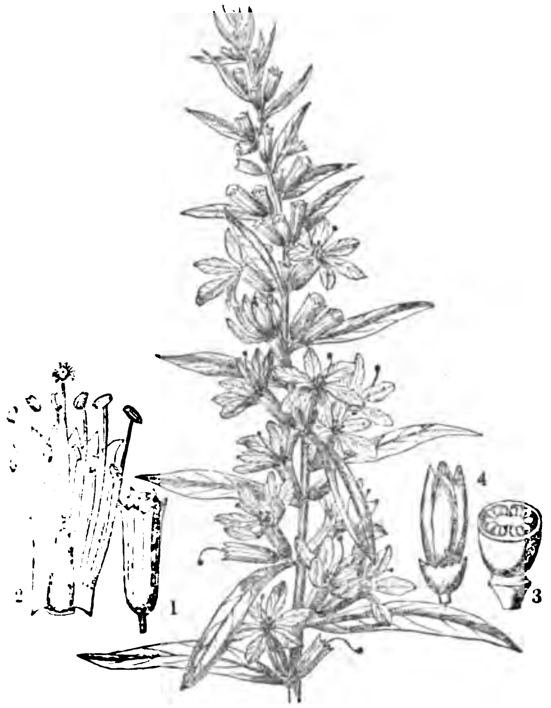
LYTHRA'CEÆ, a natural order of polypetalous Exogens, the essential character of which is to have a tubular calyx with conspicuous complete ribs, petals inserted into the orifice of the calyx, stamens springing from its base or middle, and a superior polyspermous ovary. They are most near Melastomaceæ and Onagraceæ. The order contains few plants of any interest. Some of the genus Lagerströmia are handsome Indian large-flowered bushes, represented in South America by Diplusodon; a few Ammannias have acrid leaves, which act as vesicants when applied to the skin: and the Henné dye used by Oriental women for their nails is the juice of the fruit of Lawsonia. Lythrum Salicaria, the subject of the preceding cut, is an English type of the order.



Lythrum Salicaria.

1, A flower-bud; 2, a calyx cut open and showing the insertion of the stamens; 3, a transverse section of an ovary; 4, a ripe capsule, with its four valves.

LYTTELTON, GEORGE LORD, born in January, 1708-9, the eldest son of Sir Thomas Lyttelton, Bart., of Hagley, in Worcestershire, was educated at Eton, and Christchurch, Oxford, at both of which his scholastic acquirements and promising talents gained him much credit. After travelling on the Continent for some time, he entered parliament in 1730, connected himself with the leaders of the opposition to Sir Robert Walpole, and acquired eminence and weight as a parliamentary speaker. He was a favourite of Frederic, Prince of Wales, at whose court he filled the office of secretary. After Walpole's retirement, Lyttelton was made a lord of the treasury, in 1744 He was raised in 1756 to be chancellor of the exchequer, a place for which his qualifications were but limited, if the story be true that he never could comprehend the simplest rule of arithmetic. He resigned that office to Mr. Legge in less than a year, and went out of office altogether on the dissolution of the ministry in 1759; at which time (his father being dead) he was raised to the peerage by the title of Baron Lyttelton of Frankley. The rest of his life was chiefly devoted to literature. He died in 1773.

Lord Lyttelton's literary talents in early life won the affection of Pope. His poetry, though elegant and tasteful, does not rise above mediocrity; it has however gained for him a place in Johnson's 'Lives.' Of his prose works the chief are: 'Observations on the Conversion and Apostleship of St. Paul,' 1747, the result of those studies by which, in middle life, he was converted from scepticism into a sincere and zealous believer in Christianity. This work has enjoyed a high reputation. 'Dialogues of the Dead,' 1760, a popular and amusing work. 'History of Henry II.,' to which is prefixed an account of the Revolutions of England, from the death of Edward the Confessor to the birth of Henry II., 1764-7. This is a learned, laborious, and valuable work, the fruit of twenty years' research. Miscellaneous Works, 1774. Poetical Works, 1785. Lord Lyttelton took a leading part, by his 'Account of a Journey in Wales,' in opening the eyes of the English to the beauties of their own country; and by the tasteful and expensive improvements in his celebrated park at Hagley, in introducing the modern practice of landscape gardening.

Lord Lyttelton's private character was exemplary; his acquirements extensive; his judgment as a politician and man of the world penetrating. But his indolence prevented him from doing justice to his own powers, exposed him to imposition, and led him into some embarrassments. His son Thomas lord Lyttelton, who died early in 1779, also possessed great abilities, but wasted and debased them in a profligate and unhappy life

M.

M is the labial letter of the liquid series. For the various forms of the characters by which it has been denoted in the chief European languages, see ALPHABET.

The changes to which it is liable are chiefly as follows:—

1. *M* is interchanged with *n*. Thus *m*, at the end of Latin cases and tenses, is generally represented by an *n* in Greek. Similarly the German dative *ihm* and accusative *ihn* have been confounded in the English *him*, which is at once dative and accusative. So again the German *boden*, *busen*, *besen*, *faden*, are in English *bottom*, *bosom*, *besom* or *besom*, *fathom*. And even in the Greek language, notwithstanding its aversion to a final *m*, inscriptions exhibit such forms as *τημ βουλην*, *τομ μεν μεγαν*, &c., where the nasal is modified so as to accord with the initial letter of the following word.

2. *M* with *b*. Thus in Latin, *hiems* coexists with *hibernus*, *tumeo* with *tuber*, *glomus* with *globus*, *fama* with *fabula*. This interchange explains the form of *summus*, the superlative of *sub*, of *summo* for *submo*, and perhaps that of *melior*, as the comparative of *bonus* or *belus*, the old form of *bonus*; whence *bene*, *bellus*, *βελτιων*, *βελτιστος*, *βουλομαι*, &c. Again, *βροτος* is equivalent to *μορτος*, and so related to the Latin *mor-t* and the Sanskrit *mri*. In our own language *husband* is a corruption of *houseman*, *dominus*, the correlative of *housewife*.

3. *M* with *p*. Hence the Greek forms *ομμα*, *τετυμμαι*, for *οπμα*, *τετυπμαι*, &c. So the Greek preposition *μετα* has a form *πεδα*, and the Greek *πελεια* is in Latin *palumbes*.

4. *M* with *v*. This is particularly the case in the Welsh language. Hence the name [illegible] was transferred into that tongue with a *v* (or rather an *f*, which is pronounced as *v*) in place of the *m*; and the Latin *amnis* is believed to be identical with the Welsh *Afon*, pronounced *Avon*. The Latin language too has *promulgare*, apparently for *provulgare*.

5. *M* with *w* probably. This interchange follows easily from the last, and is a natural step towards the next. The German *mit* seems to be identical with our own *with*. In Greek too *μια*, 'one,' and the particle *μεν* (which also appears to denote 'one,' and so to correspond to *δε*, 'two,' probably a corruption of *δυο*), seem to have passed through a form *Fια*, *Fεν*, before they became *ια* and *εν*. Compare the old Latin *oeno* and the English *one* as it is pronounced.

6. *M* disappearing. This appears to have been the case even at the beginning of words. See what is said above; and compare the Greek *μοσχος* with *οσχος*, *μοχλευω* with *οχλιζω*, the Latin *manus* with the Teutonic *hand*, the Latin *merere* with the English *earn*. At the end of words at least, the loss of an *m* is very common, particularly after *o*. Thus the Greek and Latin verb often has the first person ending in *ō*, where analogy would lead to *om*: *scribo*, *τυπτω*. Compare in Latin the words *sum*, *inquam*, besides the other tenses *scribebam*, *scribam*, &c.; and in Greek the middle forms *τυπτομαι*, *τυπτεαι*, *τυπτεται*, which would seem to have been formed from an old active, *τυπτομ*, *τυπτες*, *τυπτετ*, with the addition of a fixed suffix denoting *self*. In Latin all the adverbs ending in *o*, signifying *motion to*, appear to have lost an *m*, viz. *quo*, *eo*, &c. Hence *adeo*, *quoad*, occur in conjunction with a preposition which elsewhere requires an accusative. Again, an *m* has been lost in *posteā*, *anteā*, *postillā*, &c.; compare *postquam*, *antequam*, &c. Lastly, the use of *refert meā*, *refert Ciceronis*, *interest meā*, &c., are probably to be explained by the full forms, *rem fert meam*, *rem fert Ciceronis*, *inter rem est meam*. Such a use of *res* accords well with the phrases, *in rem meam est*, *e re tua est*.

7. *M*, like the other liquids, but not so frequently, is liable to change its position with regard to the vowel of a root. Thus in Greek the root *τεμ*, *cut*, may take the form *τμη*, and *δαμ-αω* has derivatives where the *μ* is next to the *δ*.

The letter M, or rather a symbol somewhat like it, for which modern printers have found it convenient to substitute that letter, was used by the Romans to denote a thousand. It is commonly said that this character was thus used because it is the initial of *mille*; but see NUMERALS.

MAAR, the German term for certain extinct volcanic craters, especially in the Eifel, which are filled with lakes. Others not different in origin are called *See*. Each term alludes to the watery expanse. Thus the Laacher See, the Maars of Daun, Ulmen, &c., are all volcanic craters, situated on eminences, but sunk so much below the level of the country as to have received the surface drainage, and to have formed a series of lakes. Those which have no apparent outlet for the waters are considered by Dr. Daubeny specially to have claims to the title of 'Maars.'

MAAS. [MEUSE.]

MAASLUYS (or Maaslandsluys) is a pretty considerable town of the kingdom of the Netherlands, in the province of South Holland, about 10 miles west of Rotterdam, in 51° 55′ N. lat. and 4° 14′ E. long. It is situated on an arm of the Maas called t'Scheur or Sluys-diep, which here empties itself into the North Sea. It has a tolerable harbour. The inhabitants, 7000 in number, are chiefly engaged in the cod and herring fisheries, the produce of which is exported in considerable quantities.

MAASTRICHT (Mastricht, or Maestricht, *Trajectum ad Mosam*), the capital of the Dutch part of the province of Limburg, is in 50° 48′ N. lat. and 5° 40′ E. long., on the banks of the Maas (or Meuse), at the junction of that river with the small stream of the *Jaar*. It is divided by the Maas into two parts, which are connected by a handsome stone bridge 500 feet in length. The part on the right bank is properly a suburb, called Wyck. Maastricht is a pretty, regular, and well built town. It contains some large squares, such as the extensive market-place, and the parade, which is surrounded with avenues of trees. Among the public buildings the most remarkable are the very handsome townhall, with a public library, in the great market-place, and the church of St. Gervais. There are six Roman Catholic, one Lutheran, and three Calvinist churches, twenty-one churches belonging to dissolved monasteries, two hospitals, two orphan asylums, and a Lyceum. The population is 22,000 inhabitants, who have considerable manufactories of woollen cloth, flannel, leather, fire-arms, soap, and extensive breweries and distilleries. In the adjacent country they likewise cultivate madder, tobacco, and succory.

Maastricht is one of the strongest fortresses in the Netherlands, and the key to the kingdom on that side. On the west side of the Maas is St. Peter's mountain (Petersberg), upon which a citadel was erected in the year 1702. The level tract between the town and St. Peter's mountain can be laid under water by means of sluices. This mountain is very remarkable on account of its fine stone quarries, to which there is an entrance on the side next the Maas, through which waggons are driven and loaded with the blocks of stone, which they convey to the banks of the river. This quarry, extending over a tract twelve leagues in circumference, is traversed by a great number of horizontal passages, which are supported by square pillars. In various places there are openings for the admission of air and light, and small water cisterns. At one place, called the Fountain, there is a pretty large basin of water, into which a small stream flows, that issues from the foot of a fossil tree. In time of war, the inhabitants of the surrounding country, with their cattle, found a secure refuge in this quarry, which is said to be capable of receiving 40,000 persons. The passages, said to be 20,000 in number, intersect and cross each other in all directions, forming such an intricate labyrinth, that it is dangerous to venture into it without an experienced guide.

(*Beschryving van het Kon. der Nederlanden*, &c., van N. G. van Kampen; Hassel's *Handbuch*; Stein, *Geog. Lexicon*; Cannabich, *Lehrbuch*.)

MAASTRICHT ROCKS. The rock of St. Peter's mountain is generally of a granular texture, and to geological observers presents a sort of middle character between chalk and particular parts of the 'calcaire grossier' of the Paris basin. The geological relation thus suggested is confirmed by the organic remains, which, with many points of specific resemblance to the ordinary fossils of the chalk, exhibit likewise some generic relations to the Tertiary series. Accordingly, the place in the scale of strata now assigned by common consent to the Maastricht rocks is in immediate superposition above the chalk of England, and at some small interval below the calcaire grossier of Paris. It may be considered as an upper part of the chalk formation, and is paralleled by observed cases in the south-west of France. It is principally to Dr. Fitton (‘Proceedings of Geol. Soc. of London,’ 1829) that English geologists owe the establishment of this important classification.

St. Peter's mountain is rich in fossils, some of which lie in flint nodules, and others in the stone. A few years ago the bones of some ruminant quadrupeds were offered for sale at Maastricht, and were described as from this hill, but they did not really belong to the antient rock. The genuine remains are however very remarkable; in particular the great aquatic reptile, imagined to be a crocodile by Faujas St. Fond, but determined to have other analogies to the Lacertiadæ by Cuvier, who named it Mosasaurus: vertebræ of this animal have been found in the chalk of England and Sweden. A very large species of marine turtle (Chelonia) has also been completely examined by Cuvier from this locality. Beautiful teeth of fishes, shells of Nautili, Baculites, Belemnites, Hippurites, Inocerami, Ostreæ, Echinida, Terebratulæ, and Polypiaria may be seen in some of the interesting collections at Maastricht, and go far to prove the truth of the prevalent opinion, that the strata of St. Peter's mountain are more allied to the chalk than to the calcaire grossier—the newest of the Secondary, rather than the oldest of the Tertiary rocks.

(Dr. Fitton in *Geol. Proceedings and Transactions;* Meyer, *Palæologica;* Von Dechen, *Handbuch*, &c.)

MABILLO'N, JEAN, born in 1632, studied at the college of Rheims. He took vows in the congregation of St. Maur, belonging to the order of Benedictines, in 1654. He afterwards assisted Father D'Achery in his collection entitled ‘Spicilegium,’ and also edited the works of St. Bernard. In 1668 he published the first volume of his ‘Acta Sanctorum Ordinis S. Benedicti,’ being the Fasti of his order, preceded by a learned introduction, ‘Præfationes in Acta Sanctorum.’ Mabillon was afterwards sent to Italy by Louis XIV. to make a collection of books and MSS. for the royal library. On his return he published his ‘Museum Italicum,’ 1689, a kind of literary and antiquarian itinerary of Italy, in which he briefly describes the towns that he visited, and more at length the churches and convents, especially those of his order, such as Monte-Casino, Vallombrosa, &c., the libraries and colleges, the rare MSS., inscriptions, and other curiosities. This work is followed by learned dissertations upon subjects of ecclesiastical history and palæography. The second volume of the ‘Museum Italicum’ is occupied by a ‘Commentarius in Ordinem Romanum,’ or Commentary on the ritual of the various services, or liturgy, and ceremonies of the Roman Church, which are there exhibited at full length. He had previously published ‘De Liturgia Gallicana libri tres,’ 1685, in which he compares the Gallican with the Mozarabic liturgy

Mabillon wrote also the ‘Iter Germanicum,’ being a similar tour through part of Germany, namely, Suabia, Helvetia, and Bavaria, which he likewise undertook by order of Louis XIV. In this journey he visited the abbeys and libraries of St. Gall, Augsburg, &c., and among others the secluded Benedictine convent of Tegern See, where he and his companion met with a very scurvy reception from the librarian, a rough Bavarian, who hated them as being Frenchmen, and the more so as they caused him to be called out of the refectory to attend upon them. He also wrote an ‘Iter Burgundicum,’ which is among his posthumous works: ‘Ouvrages Posthumes de D. Jean Mabillon et D. Thierri Ruinart, Bénédictins de la Congregation de St Maur,’ 3 vols. 4to., Paris, 1724. This interesting collection contains, among other valuable matter, Mabillon's correspondence, and his ‘Reflexions sur les Prisons des Ordres Religieux,’ in which he censures the cruelties practised in several monastic houses against those monks who transgressed the rules of their order, and speaks among others of the famous *Vade in Pace*, or subterraneous dungeons in which some were confined till they died. This strange authority exercised by communities over the liberty and life of individuals, uncontrolled by and unknown to the state, is one of the most repulsive features of the monastic system.

In the above collection of Ouvrages posthumes are: ‘scours sur les Anciennes Sepultures de nos Rois,’ ‘Remarques sur les Antiquités de l'Abbaye de St. Denis,’ ‘Histoire de la Contestation sur l'Auteur de l'Imitation de Jesus Christ’ [KEMPIS, THOMAS A], ‘Lettres et Ecrits sur les Etudes Monastiques.’ These last concern a curious controversy between the Abbé de Rancé, the founder of the order of the Trappists, and the Benedictines. De Rancé, in his ascetic enthusiasm, had forbidden his monks all scientific studies, and indeed all reading except the Breviary and a few monastic tracts. The rest of the clergy, both secular and regular, took the alarm, and Mabillon was requested to defend monastic studies and learning as perfectly compatible with piety and religious discipline, as the Benedictine order had fully proved. Mabillon accordingly wrote his ‘Traité des Etudes Monastiques,’ in 1691, which was received with great applause, and was translated into Latin and other languages. This led to a controversy with Rancé, who had the worst of it: ‘Réflexions sur la Réponse de l'Abbé de la Trappe,’ 1692. Another controversy which Mabillon had with Rome concerning the worship of relics of unknown persons whose bones were found in the catacombs, fills part of the posthumous works: ‘Lettres et Ecrits sur le Culte des Saints inconnus.’ They contain also a ‘Votum D. Io. Mabillonis de quibusdam Isaacii Vossii Opusculis.’ While Mabillon was at Rome, he was asked his opinion by the Congregation of the Index concerning some writings of Isaac Vossius, in which that scholar gave the preference to the chronology of the Septuagint over that of the Hebrew text, and in another place maintained that the deluge had not been universal. Mabillon said that although he believed that the opinions of Vossius, especially the latter, were not correct, yet he did not think that they constituted heterodoxy, and accordingly the Congregation did not place Vossius in the Index.

Mabillon wrote also ‘De Re Diplomaticâ libri sex accedit Commentarius de antiquis Regum Francorum Palatiis;’ ‘Veterum Scripturarum varia Specimina,’ &c., a work much esteemed. In 1701 he was chosen member of the Academy of Inscriptions, and in 1703 he published the first volume of his ‘Annales Ordinis S. Benedicti,’ which he brought down to the year 1157, 6 vols. folio. He died at Paris, in 1707. Mabillon was one of the most learned men of his age, and his liberal and candid disposition is clearly exhibited in his ‘Correspondence,’ and in his other posthumous writings.

MABLY, ABBE' DE, born at Grenoble in 1709, studied at Lyon in the Jesuit College, and afterwards went to Paris, where he was introduced to the Cardinal de Tencin, who was then minister. He wrote in 1740 his ‘Parallèle des Romains et des Français,’ which acquired him a kind of popularity. He was employed by the cardinal as his secretary, and while in that office he compiled his ‘Droit public de l'Europe, fondé sur les Traités,’ a useful work derived from good sources. Mably was employed in several secret negotiations between 1743-6, after which he appears to have quarrelled with the cardinal, in consequence of which he gave up his official prospects for a studious retirement. His historical works are:—1. ‘De la manière d'écrire l'Histoire;’ 2. ‘De l'étude de l'Histoire;’ 3. ‘Observations sur l'Histoire de la Grèce;’ 4. ‘Observations sur les Romains;’ 5. ‘Observations sur l'Histoire de France,’ 2 vols. 12mo., [illegible], with a posthumous continuation in two more volumes, published in 1790 (this is the best of his historical works); 6. ‘Entretiens de Phocion sur le Rapport de la Morale avec la Politique.’ Many of the author's views, especially in this last work, are visionary; such as a community of goods; he would also banish commerce and the fine arts from a republic. Mably was a great admirer of the institutions of Sparta. He died at Paris in 1785.

MABOU'IA, Fitzinger's name for a genus of Saurians allied to the Skinks (*Scincus*).

MABUSE, or MAUBEUGE, JOHN. This eminent painter, whose proper name was John Gossaert, was born at Maubeuge in Hainault, in 1499. Nothing is known of his parents, or of the name of the master under whom he studied. It is evident however that in early life he must have very assiduously devoted himself to the study of nature, and have acquired habits of industry. Considering that he was in after-life of a most restless ardent temperament, indulging in dissolute and licentious habits, and especially addicted to immoderate drinking, we cannot but admire the patience, fidelity, and labour which appear in his works. Most writers have affirmed that he went early to Italy, but even this is not clearly ascertained; but whatever advantage he may have derived from the study of the great masters and of the antique, he never attained the elegance of the Roman school.

After his return from Italy he lived for some time at Utrecht, in the service of the bishop, Philip of Burgundy. From Utrecht he went to Middelburg, where he painted the celebrated altarpiece, representing the Descent from the Cross, for the great church. This picture, which was of extraordinary dimensions, was highly admired by Albert Durer. The church, with this picture and all the treasures of art that it contained, was destroyed by lightning. He seems to have lived in a very extravagant manner at Middelburg, and was at last thrown into prison; but whether for debts or for some excesses is not known. It seems to have been after the recovery of his liberty that he came to London, where he was employed in the service of Henry VIII. He painted the king's children, and many portraits of the nobility, which gained him great reputation. Several of his pictures painted in England are still in existence, and others were destroyed in the fire at Whitehall Palace. One of his finest works is at Castle Howard, the seat of the earl of Carlisle. It represents the Wise Men's Offering, and is a rich composition, in which there are thirty principal figures. Dr. Waagen, in his 'Arts and Artists in England,' speaks in the highest terms of this picture, which is in as good a state of preservation as if it had been finished only yesterday. Most of the great galleries on the Continent have specimens of his works. Among these are three in the celebrated collection formed by Messrs. Boisserée, which contained above 300 pictures by the antient German masters, which they saved from neglect or destruction during the wars of the French revolution, and which are now in the possession of the king of Bavaria. These pictures are a very large and splendid composition, representing the Crucifixion, the archangel Michael overcoming Satan, and a small highly-finished picture representing the Virgin Mary as Queen of Heaven. This is conjectured to be the picture which was most highly extolled during his lifetime, and which he painted while in the service of the marquis of Verens, a wealthy Flemish nobleman, and in which he took the marchioness and her son as models for the Virgin and Child. This nobleman having to entertain the emperor Charles V., put all the persons in his service into new and splendid liveries, and among the rest ordered suits of rich white brocade for his painter and two others of his household. Mabuse, under some pretence, got possession of the brocade, which he sold, and spent the produce at a tavern. When the great day came, and the retainers and servants were to pass in procession before the emperor, the dress of Mabuse appeared to be of such superior whiteness and beauty, that the emperor desired to examine it, and, to his astonishment, discovered it to be paper: thus the secret came out, and greatly amused the company. It is said that Mabuse died in 1562, but neither the place nor manner of his death is known.

Such are the particulars which we have been able to collect of the life of this artist. Three different accounts of him now before us agree in giving the dates of 1499 and 1562 as those of his birth and death. There is however one circumstance which is absolutely irreconcileable with these dates. In the catalogue of the pictures belonging to King Charles I. is 'The children of Henry VII.: Prince Arthur, Prince Henry (afterwards Henry VIII.), and Princess Margaret.' Dr. Waagen, who saw this picture at Hampton Court, says, 'As Prince Henry, who was born in 1492, appears to be about seven years old, the picture was painted about 1499, which fixes the time when Mabuse was in England;' but 1499 was the year in which all the accounts fix the birth of the artist himself.

MACA'CO. [Lemuridæ, vol. xiii., p. 419.]

MACA'CUS, a barbarous word founded on the term *Macaco* (written by the French *Macaque*), which, according to Cuvier and the author of 'Natural History of Monkeys, Lemurs, and Opossums,' appears for the first time in Marcgrave's 'Nat. Hist. of Brazil,' as the native appellation of a kind of monkey found in Congo and along the coasts of the Gulf of Guinea. The author of 'The Natural History of Monkeys,' &c. observes that its application to an Asiatic species, of a genus totally distinct from that to which the animal properly bearing it really belongs, is one of the many similar errors of nomenclature committed by Buffon, at that time indeed unavoidable from the very limited knowledge which naturalists possessed on the subject of specific distinctions, and especially from the confusion which reigned in the geographical part of zoology.

Lacépède seems to have been the first who Latinized this term, and he was followed by other French zoologists as well as by those of other countries. The *Ouanderow* or *Wanderow* appears to be considered the type of the genus, at least it stands at the head of the heterogeneous species comprehended under the title.

Thus Cuvier arranges under the *Macaques* the following *Simiadæ*: *Silenus*, *Sinica*, *radiata*, *cynomolgus* and *cynocephalus*, *rhesus*, *nemestrina*, &c.

Mr. Gray arranges the genus as the last of his subfamily *Cercopithecina* (family *Hominidæ*).

M. Lesson, who makes the characters of the genus consist in a facial angle of from 40 to 45 degrees; in a very strong development of the supraciliary and occipital crests; the presence of pouches and callosities, and a tail more or less long, gives as its dental formula that which is common to so many of the *Simiadæ*, viz.:

$$\text{Incisors } \frac{4}{4};\ \text{Canines } \frac{1-1}{1-1};\ \text{Molars } \frac{5-5}{5-5}=32:$$

and he arranges under it the following species: *Silenus*, *Sinicus*, *carbonarius*, *radiatus*, *cynomolgus*, *rhesus*, *nemestrinus*, and *speciosus*.

Sir William Jardine adopts the genus with the following species: *Macaci*, *Silenus*, *Sinicus*, *radiatus*, *cynomolgus*, *rhesus*, *nemestrinus*, and *niger*.

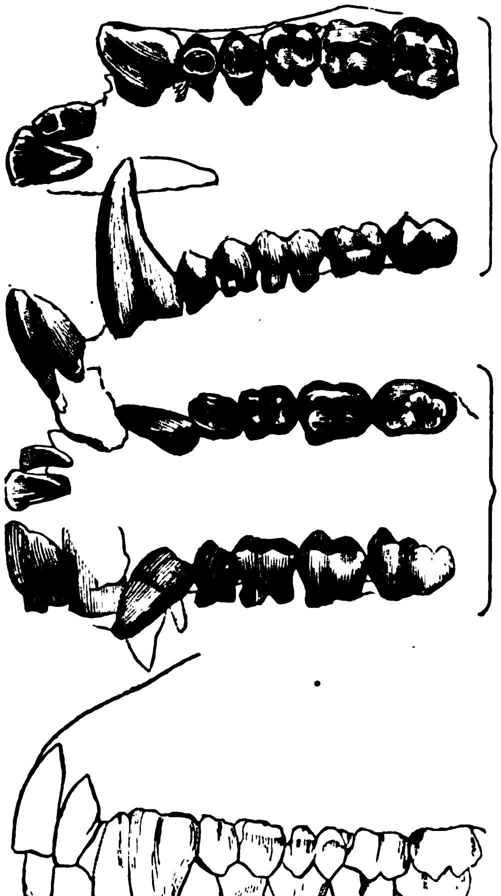
Mr. Swainson, who also adopts the genus, gives the species the English appellation of *Ape-Baboons*, and he considers that they are distinguished by an elongated muzzle, as in *Macacus carbonarius*, much more prominent than in the *Cercocebi*, and by a tail more or less lengthened: he is also of opinion that they differ from the *Cyanocephali* (Cynocephali) of Cuvier, or True Baboons, because their nostrils 'open obliquely on the upper part of the muzzle.' Mr. Swainson thinks that the form of these animals, nevertheless, shows a strong resemblance to the *Cercocebi*, which is further increased by their possessing a tail; although this member is generally so short that it seldom equals a third of the length of the body. The muzzle, he observes, is so much elongated, that the facial angle does not exceed 45°, and the canine teeth are strong and large. He further remarks that it deserves attention, that some of the species (as *M. Silenus*, *Sinicus*, and *radiatus*) are remarkable for having crests, which either assume the form of a mane or of a radiated tuft. The Chinese Bonnet Monkey has the hairs disposed in this manner, while its elongated muzzle, in Mr. Swainson's opinion, is very characteristic of the genus, and he states that the form of these animals separates them widely from the monkeys: it is, he says, strong and compact, while their disposition is cunning and mistrustful. He concludes by remarking, that the crested species inhabit India, and that the others are African. (*Nat. Hist. and Classification of Quadrupeds.*)

The author of the 'Natural History of Monkeys, Lemurs, and Opossums' rejects, for substantial reasons given in that work, the genus *Macacus*, and applies the term *Baboons*, as usually understood and applied in the English language, to a group of *Simiæ* co-ordinate with the *apes* and *monkeys*, as described by him, distinguished from the apes by the equality of their members, their cheek-pouches and ischial callosities, and from the monkeys by the short robust make of their bodies and extremities, their tubercular tails, too short to execute the functions usually assigned to that organ, and the mountain rather than sylvan habitat which this conformation necessarily induces.

'The most prominent of these traits of structure,' continues the author, 'the abbreviated or tubercular nature of the tail, is the idea usually attached to the word *baboon*, and it is certainly the most prominent and characteristic attribute of the group; since, as we have frequently had occasion to observe, the comparative development of this organ, if not the immediate cause, is at all events the most certain index of the habits and economy of these animals:' and he makes the baboons thus defined comprise two distinct genera, *Papio* and *Cynocephalus*, respectively confined, with one or two exceptions, to the continents of Asia and Africa.

The author then introduces to the reader's notice the genus *Papio* as the last and lowest of the groups which inhabit the Asiatic continent and the great islands of the Indian Archipelago, and which appear to occupy in these regions the situation which the *Cynocephali* fill in Africa. Of the forms placed by the author under this genus the *Wanderoo* and *Gelada* (*Papio Silenus* and *Papio Gelada*) are the only species in which the tail acquires any length: it never reaches, he remarks, beyond the houghs, nor is it ever employed to assist the progressive motions of the animals as among the *Cercopitheci*. These species, therefore, he thinks cannot be separated with any kind of propriety from the *Papios* with tuberculous tails, merely on account of their comparative length; because that organ, though rather more developed in the Wanderoo and Rhesus than in the Magot and Papio niger, is still greatly abbreviated as compared with the tails of the *Cercopitheci*, and entirely devoid of influence as an element in the habits and economy of animal life.

The following is given by M. F. Cuvier as the dental development of the *Macaques* and *Cynocephales*, and is taken from the Chinese Bonnet Monkey (*Macaque Bonnet Chinois*)



Teeth of Macacus, &c.

Reverting to the arrangement of the author of the *Natural History of Monkeys*, &c., we find the Papios divided into two small groups, distinguished by the greater or less length of the tail on the one hand, and its tuberculous form or total absence on the other; of the latter the well-known *Magot*, or Barbary Ape, is an example, and the Wanderoo[*] (*Macacus Silenus* of authors, *Papio Silenus* of the author of the *Nat. Hist. of Monkeys*), is an illustration of the former.

Description of the Wanderoo.—Hair deep black throughout, with the exception of the long beard or mane, which descends on each side of the face in the form of a ruff, extending downwards over the chest, and varying from an ash-gray to a pure white. The upper part of the face between the eyes naked and flesh-coloured; the muzzle perfectly black. Cheek-pouches large, callosities of considerable size, and flesh-coloured. Tail about half as long as the body, and when perfect, which in captivity is not often the case, terminating in a brush of tufted hairs (Bennett.)

Geographical Distribution.—Peninsula of India, Ceylon? (Knox). M. Duvaucel saw the animal in the menagerie at Barracpore, and states, according to M. F. Cuvier, that the Indians give it the name of *Nil bandar*, or perhaps, as the author of *Nat. Hist. of Monkeys* observes, more properly *nyl* or *neel bhunder*, signifying the dark blue or black bhunder; but this, continues the last-mentioned author, evidently refers merely to the colour of the hair, and can scarcely be the real appellation of the animal, which, not being a native of Bengal, is not likely to have a Bengalee name.

Habits, &c.—Father Vincent Maria gives the following quaint account of this species. 'There are found,' says the Padre, 'four sorts of monkeys on the coast of Malabar; the first is quite black with glossy hair and a white beard round the chin, measuring rather more than a palm in length. The other monkeys pay to this so profound a respect that they are humble in his presence, as though they appreciated his superiority. The princes and mighty lords hold him in much estimation for his endowments of gravity, capacity, and the appearance of wisdom above every other monkey. He is readily trained to enact a variety of ceremonies and affected courtesies, which he goes through with so grave a face, and so perfectly, that it is a most wonderful thing to see them so exactly performed by an irrational creature.'

The general posture of the species is on all fours or seated; in which positions it usually takes its food, either by the hands or by bringing the mouth to it. Its first operation in feeding is generally to fill the cheek-pouches.[*] It sleeps either on its side or sitting, bent forward, and with the head on the breast. Those which we have seen in captivity have exhibited varied temperaments. One in particular was all life, spirit, and mischief, while another was melancholy and staid in its deportment; and yet the health of both these animals appeared to be equally good, nor was there much difference in their ages.

Wanderoo.

MACAO, a town in China, situated at the southern extremity of the æstuary of the Choo Kiang, or Canton river, 22° 13′ N. lat. and about 113° E. long., about 80 miles from Canton by sea. It is built on a low sandy promontory, stretching southward from the island of Macao, which is separated by a narrow channel from the larger island of Kiang-shan-shien. The town extends across the central part of the peninsula from the roadstead of Macao on the east to the interior harbour on the west, and is somewhat more than half a mile wide in that direction, whilst from north-east to south-west it occupies about two miles. The streets are regular, but mostly narrow. A considerable number of houses have been built by the Portuguese and other European inhabitants in the European style, but the greater part are Chinese buildings. There are some churches and convents in the town, and also three small fortresses in the neighbourhood. A wall built by the Chinese across the isthmus is carefully guarded by them, and the Europeans are not permitted to pass it. The roadstead of Macao is much exposed to the prevalent gales during the monsoons. The interior harbour is spacious, well sheltered, and has excellent anchoring ground; but being situated out of the route to Canton, and open only to the south-west, it cannot well be used during the south-western monsoons. For that reason it is rarely entered by vessels, which commonly lie in the harbour, called Typa Cabrado, which is formed by four small rocky islands, lying south of the southern extremity of the peninsula on which Macao is built. This harbour is not large, but as these islands are high and enclose it almost completely on all sides, it is perfectly safe, even during the heaviest gales. The entrance for vessels is from the east, but boats may pass through the northern channel direct to the town, which is only about two miles distant. About 20 miles north-east of Macao, farther up the estuary, is the rocky island of Lintin, on the western side of which is excellent anchor-ground, where the larger vessels lie-to before they proceed to Canton, and where an extensive smuggling trade is carried on.

---

[*] Lion-tailed Baboon of Pennant.

[*] 'First mouthed, last swallowed.'—Hamlet.

It is commonly supposed that the Portuguese possess the sovereignty of Macao; but that is so far from being the case, that they pay a ground-rent amounting to 500 taels per annum, and Chinese mandarins inspect periodically the Portuguese forts, as well as levy a duty on the Macao shipping. A civil mandarin, called Tso-tang, resides within the town, as governor in the name of the emperor of China; he keeps a watchful eye on the inhabitants, and communicates information to his superiors. The only privilege which the Portuguese possess is to govern themselves; while the Chinese population of the town are entirely under the control of the mandarins. The former, including slaves, does not exceed 5000, while the Chinese are calculated to be above 30,000. Besides the Portuguese, individuals of other European nations reside in the town, especially Englishmen, who pass the summer months there, and go to Canton in autumn, when the vessels arrive.

The trade of Macao was formerly considerable, but it has been continually decreasing. The Portuguese are permitted to employ twenty-five vessels in this trade, but they actually do not possess much more than half that number. The most lucrative branch was the smuggling trade in opium, which has almost entirely passed to the island of Lintin. (Horsburgh; *The Chinese*, by Davis.)

MACARTNEY, GEORGE MACARTNEY, EARL OF, was the only surviving son of George Macartney, Esq., a gentleman of Scottish descent, but whose family had been for some generations settled on their estate of Lissanoure, near Belfast in Ireland, where the subject of the present notice was born on the 14th of May, 1737. At the age of thirteen he was admitted a fellow-commoner of Trinity College, Dublin, and in 1759, after having obtained his degree of M.A., he came to London, where he entered himself of the Inner Temple, but without any intention of prosecuting the profession of the law. He then made the tour of Europe, and on his return home in 1764 it was arranged, through the interest of Lord Holland, with one of the members of whose family he had formed an intimacy on the Continent, that he should be returned to the British parliament for Midhurst, under the patronage of the earl of Sandwich, then one of the secretaries of state; but this destination was changed by his appointment, 22nd August of the same year, as envoy extraordinary to the empress of Russia, for the purpose of concluding a commercial treaty with that country. He was knighted before proceeding on this business, which, after a long and arduous negotiation, in the course of which he was not only opposed by rival ministers at the court to which he was sent, but thwarted by very annoying conduct on the part of the British cabinet, he at last brought to a satisfactory conclusion. He returned to England in June, 1767, and soon after received the appointment of ambassador extraordinary and plenipotentiary to Russia, which however circumstances induced him to resign.

In February, 1768, he married Lady Jane Stuart, second daughter of the earl of Bute; and in April was returned to parliament for Cockermouth. In July following he exchanged this seat for one in the parliament of his native country, having been elected for Armagh in contemplation of his appointment to the office of chief secretary for Ireland, which took place on the 1st of January, 1769, on the nomination of Lord Townshend as lord-lieutenant, and the adoption of a new scheme of government, under which the lord-lieutenant should be, not, as heretofore, an occasional visitor only, but a permanent resident in the country.

Macartney, who was now sworn of the Irish privy-council, greatly distinguished himself by his exertions in the debates of the House of Commons against Flood, Dr. Lucas, and the other leaders of the opposition. He held his office till June, 1772, when he was made a Knight of the Bath, and in 1774 was appointed to the sinecure of governor of Toome Castle, which produced an income of above 1000*l*. In October, 1774, he was returned to the British parliament as member for the Ayr burghs; but in December, 1775, he was sent abroad as governor of the island of Granada. He was raised to the Irish peerage by the title of Baron Macartney, 10th of June, 1776. He remained in Granada till July, 1779, when after a most gallant defence he was compelled to surrender the island at discretion to the French admiral Count d'Estaing, and was himself sent prisoner to France. He was however very soon exchanged, and after having been employed by Lord North in a confidential mission to Ireland, was in September, 1780, again returned to the British parliament for Beeralstone.

On the 14th of December of the same year he was appointed by the East India Company governor of Madras. Having returned to England in January, 1786, he found that before his arrival he had been appointed governor-general; but the state of his health and other considerations induced him to decline that post, and it was eventually given to Lord Cornwallis. Very soon after his return home Macartney was severely wounded in a duel with Major-General Stuart, an officer whom he had when in India found it expedient to remove from the service. In 1788 he took his seat for the first time in the Irish House of Peers, and he resided chiefly in his native country till 1792, when he was appointed to his most memorable public employment as ambassador extraordinary to Pekin. Having on the 28th of June been made an Irish viscount, he sailed on the 26th of September, taking with him as his secretary his old friend Sir George Staunton, by whom the account of the embassy was afterwards given to the public. The amount of the benefit gained by this first diplomatic communication on the part of England with the court of Pekin has been matter of dispute; but it is generally agreed that no other person could have accomplished more than was done by Lord Macartney, whose conduct at least was well calculated to impress the subjects of the Celestial empire with a respect for the country which he represented. He left China on the 17th of March, 1794, and landed at Portsmouth on the 5th of September of the same year, having on the 1st of March previous been made Earl Macartney in the Irish peerage.

In June, 1795, he was sent on a confidential mission to Italy, from which he returned in May, 1796; and having on the 8th of June been made a British peer by the title of baron Macartney, he was in the end of the same year appointed governor of the newly captured territory of the Cape of Good Hope. Here he remained till November, 1798, when his impaired health compelled him to return to England. The same cause induced him to refuse the office of president of the Board of Control, with a seat in the cabinet, which was offered him on the formation of the Addington ministry in 1801; and he lived in retirement, suffering severely from gout, till his death, at Chiswick, 31st March, 1806. The manner in which Lord Macartney discharged his duty in the various public services in which he was employed procured him from all parties the reputation of very considerable ability and the highest honour. An account of his public life, with a selection from his unpublished writings, has appeared by Mr. (now Sir) John Barrow, in 2 vols. 4to, London, 1807, with his portrait prefixed. His writings here printed, which occupy the second volume, consist of extracts from an 'Account of the Russian Empire,' 'A Sketch of the Political History of Ireland,' and 'A Journal of his Embassy to China.' The manuscript of the 'Account of Russia' is in the king's library at the British Museum, and also a printed but not published copy of the same tract, in 8vo., dated London, 1768. The Life occupies the first four hundred and twelve pages of the first volume of Sir John Barrow's work.

M'CARTHY, SIR C. [ASHANTEES.]

MACASSAR. [CELEBES, vol. vi., p. 400.]

MACAUCO. [LEMURIDÆ, vol. xiii., p. 419.]

MACAULAY, CATHARINE, was the daughter of John Sawbridge, Esq., of Ollantigh, in Kent, where she was born in 1733. She took the name by which she is best known from her first husband Dr. George Macaulay, a London physician, to whom she was married in 1760. It was soon after this date that she commenced authoress, by the publication of her 'History of England from the accession of James I. to the elevation of the House of Hanover,' the first volume of which, in 4to., appeared in 1763, and the fifth and last, which however only brought the narrative down to the Restoration, in 1771. The work also went through more than one edition in 8vo. On its first publication it attracted considerable attention, principally from the double piquancy of the sex and the avowed republicanism of the writer; but, notwithstanding some occasional liveliness of remark, and its notice of a good many facts omitted by most of our other historians, it has not been found to have merit enough to compensate for its inflamed and narrow partisanship, the loose shambling gallop of the style, and its general character of common-place and superficiality, so that it has long passed into the oblivion of waste paper. The five volumes of the History were followed, in 1778, by another, entitled 'The History of England from the Revolution to the present time, in a series of Letters to the Reverend Dr. Wilson, rector of St. Stephen's, Walbrook, and prebendary of Westminster,' 4to., Bath. The six letters of which this volume consists come down to the termination of the administration of Sir Robert Walpole, in 1742.

In 1778, or according to another account, in 1785, Mrs. Macaulay, having lost her first husband, married a Mr. Graham, of whom all that is told is that he was so many years her junior as to expose the lady to much irreverent remark. She also wrote several pamphlets, both during the progress of her great work, and after its completion. Of these the catalogue-makers have preserved the following titles:—'Remarks on Hobbes's Rudiments of Government and Society,' 1767, enlarged and republished in 1769, with the more striking title of 'Loose Remarks on some of Mr. Hobbes's Positions;' 'Observations on a Pamphlet (Burke's) entitled Thoughts on the Causes of the present Discontents,' 1770; 'An Address to the People of England, Scotland, and Ireland, on the present Important Crisis of Affairs,' 1775; 'A Treatise on the Immutability of Moral Truth,' called in a second much enlarged edition, 'Letters on Education,' 1790; and 'Observations on the Reflections of the Right Hon. E. Burke on the Revolution in France, in a Letter to the Right Hon. the Earl of Stanhope,' 1791. In 1785 she made a voyage to America to visit Washington. On her return, she retired with her husband to a small house in Leicestershire, where she died on the 22nd of June, 1791. In 1790 was printed a little volume entitled 'A Catalogue of Tracts,' which a manuscript annotation on the copy in the royal library in the British Museum states to be 'Mrs. Macaulay's,' meaning apparently the tracts in her library. The titles are between 5000 and 6000 in number, besides about 1300 sermons. Chalmers (*Biog. Dict.*) refers for further information respecting Mrs. Macaulay to the *Gentleman's Magazine*, vols. xl. and lxi.; *British Critic*, vol. iv.; Baldwin's *Literary Journal*, vol. i.; Boswell's *Life of Johnson;* and Wilkes's *Life and Letters*. There is a medallion profile of Mrs. Macaulay prefixed to the 3rd vol. of the original edition of her History, published in 1767; and the frontispiece to the volume of letters to her friend Dr. Wilson presents a monumental full-length figure of her, apparently copied from a monument which the zeal of Wilson had induced him to erect to her in his church, but which was removed by the opposite zeal of his successor in the living.

MACAW. [PSITTACIDÆ.]

MACCABEES (οἱ Μακκαβᾶιοι), a Jewish family celebrated for their heroic resistance to the oppression of the Greek kings of Syria in the second century before the Christian æra. Their genealogy has been given under ASMONÆANS. Though the name Maccabees is applied to the whole family of Mattathias, and is often used even with a wider signification, it belonged properly only to Judas, the third son of Mattathias, who was surnamed Maccabæus (מַקָּבִי, *the hammerer*) on account of his prowess in war. (1 *Macc.*, ii. 4.) Others derive the name from the initial letters of the phrase מִי כָמֹכָה בָּאֵלִם יְהֹוָה, 'Who among the gods is like thee, O Jehovah?' (*Ex.*, xv. 11), which they suppose to have been inscribed on the banner of the Maccabees. If this were the case the Greek form would be Μαχαβᾶιοι, not Μακκαβᾶιοι.

Antiochus Epiphanes, on his return from his second campaign in Egypt, took Jerusalem by storm, polluted the Temple, carried away from it the sacred utensils and treasures, and made Philip the Phrygian governor of Judæa (B.C. 169). Two years later, after his last Egyptian expedition, he commenced a furious persecution of the Jews. Apollonius, his chief collector of tribute, was sent to Jerusalem, which he attacked and plundered, massacring many men, and making the women and children captives. He fortified Mount Sion, and placed in it a Syrian garrison. At the same time Antiochus issued an edict that all his subjects should adopt the same usages; and not content with this blow at the religion of the Jews, he sent orders forbidding them the exercise of their religious rites, and commanding them to sacrifice to idols, to profane the Sabbath, and to discontinue circumcision. Resistance to these commands was made a capital offence, and many of the Jews were put to death; while some saved themselves by fleeing into the wilderness, and others conformed to the idolatrous rites imposed upon them. The books of the law were sought for and destroyed, and whoever kept them was put to death. Jerusalem was deserted, and the Temple was polluted a second time. An old man, named Athenæus, who was sent by Antiochus to instruct the Jews in the Greek religion, placed on the great altar a smaller altar to Jupiter Olympius, which the author of the first book of Maccabees calls 'the abomination of desolation' (1 *Macc.*, i. 54), alluding, it is generally supposed, to the prophecy of Daniel (viii. 13; xi. 31; xii. 11). In consequence of this the daily sacrifice ceased on the 15th of the month Chasleu, which answered to parts of December and January, B.C. 168-7. (Clinton's *Fasti*, vol. iii., p. 321.) The officers of Antiochus were sent through the cities of Judæa to enforce the king's edict. Some of them came to Modin, where Mattathias dwelt and lamented with his five sons over the state of Israel. Upon the attempt being made to compel the people of the city to sacrifice to idols, Mattathias made an open resistance, killed a Jew who came to sacrifice, slew the king's officer, and pulled down the altar. He then fled to the mountains with his sons and their adherents. About the same time some Jews who had taken refuge in the wilderness were attacked on the Sabbath by Philip, the governor of Judæa, and massacred without resistance to the number of a thousand. In consequence of this Mattathias and his party resolved not to abstain from fighting on the Sabbath. Being now joined by the Assidæans, a sect of very strict religionists, and others, Mattathias went through the Jewish cities destroying the altars of idols, punishing the apostate Jews, and enforcing the law of Moses. In the midst of this successful course Mattathias died, having appointed his third son, Judas Maccabæus, his successor in the military-command, and his second son Simon Matthes, to be his brother's counsellor (B.C. 166). Judas pursued his father's career of victory. He defeated and slew Apollonius, the governor of Samaria; and with a small force put to flight a large army under Seron, the lieutenant of Ptolemy Macro, governor of Cœle-Syria. Antiochus now gathered an immense army, with part of which he marched against the Armenians and Persians, leaving the remainder under Lysias to act against the Jews. Judæa was presently invaded by 40,000 infantry and 7000 horse, under Ptolemy Macro, Nicanor, and Gorgias. Judas had only 6000 men; but by a skilful manœuvre he surprised the Syrians in their camp, and completely routed them. Next year he defeated an army of 60,000 foot and

3000 horse, commanded by Lysias himself, and by this victory became master of Judæa. His first care was to purify the Temple, which he did on the 25th of the month Casleu, B.C. 165-4, exactly three years after its pollution. An annual feast of eight days was established in commemoration of this event. In the mean time Judas attacked the Syrian garrison on Mount Sion, which however he was unable to reduce, and fortified the Temple and the fortress of Bethsura, near Jerusalem. His attention was now occupied by the attacks of the neighbouring idolatrous nations, whom he and his brothers Simon and Jonathan repeatedly defeated. Enraged at these events, Antiochus marched in great haste to invade Judæa, but died on his way in the greatest agony, confessing that he suffered for his cruelty to the Jews (B.C. 164 or 3). The Jews now enjoyed a short interval of peace with Ptolemy Macro, upon whose death however the war with the neighbouring nations broke out afresh, and Judæa was once more invaded by Lysias, who had possession of the person of Antiochus Eupator, the infant second successor of Epiphanes. Lysias was defeated, and concluded a peace with Judas. But not long after this, at the instigation of some idolatrous Jews who had escaped from the castle on Mount Sion, Lysias and the king again invaded Judæa with 100,000 foot, 20,000 horse, 32 elephants, and 300 war chariots. Before this force Judas was compelled to retreat, after fighting one great battle, in which his younger brother Eleazar Savaran died in performing an heroic action. (1 *Macc.*, vi. 43-46.) Bethsura was taken, and the Jews were closely besieged in the Temple, when Lysias was compelled, by the state of affairs in Syria, to grant them peace on favourable terms; but before leaving Jerusalem he demolished the fortifications of the Temple. Under Demetrius Soter the war was renewed at the instigation of Alcimus, who aspired to the high-priesthood. The Syrian armies sent under Bacchides and Nicanor to support his claims were defeated by Judas, and Nicanor himself was killed in battle at Capharsalama. During the short interval of peace which followed, Judas made an alliance with the Romans. But in the next year (B.C. 160) another army entered Judæa under Bacchides and Alcimus, and Judas Maccabæus fell in battle.

The Syrians were now for a time masters of the country, and Alcimus was established in the priesthood. About this time John, the eldest son of Mattathias, fell into an ambush of the enemy, and was put to death. In the following year Alcimus died in agony while engaged in violating the sanctity of the Temple; and Bacchides left Judæa, which remained in peace for two years under the government of Jonathan Apphus, the youngest of the Maccabæan family. At the end of this period another invasion of the Syrians was repelled, and Bacchides made peace with Jonathan, whose authority became fully established. The subsequent history of the Maccabees has already been given fully enough under ASMONÆANS. See also ANTIOCHUS; JEWS; JUDAS MACCABÆUS; JONATHAN APPHUS; and SIMON MACCABEE.

(The 1st and 2nd books of *Maccabees*; Josephus; Jahn's *Hebrew Commonwealth*; Prideaux's *Connection*; Winer's *Biblisches Realwörterbuch*.)

MACCABEES, THE BOOKS OF THE. Five books have come down to us under this title.

1. The *First Book of the Maccabees* contains the history of the Jews during forty years, from the accession of Antiochus Epiphanes to the death of Simon Maccabæus, B.C. 135.

The author is unknown. Some suppose the book to have been compiled from the memoirs of the Maccabæan princes, perhaps by John Hyrcanus, about the close of whose reign internal evidence would lead us to fix its date. (1 *Macc.*, xvi. 23.) The general opinion of critics is that it was written in Hebrew. Origen and Jerome assert that they had seen the Hebrew original, and the Greek copy which we possess bears internal evidence of being translated from Hebrew. It forms part of the Septuagint, and there is an ancient Latin version made from the Greek, and a Syriac version, which Michaelis supposes to have been translated from the Hebrew. This book is considered the best authority for the history of the period to which it relates.

2. The *Second Book of the Maccabees* begins with two letters which are not connected with each other, nor with the rest of the book. It then mentions some events which preceded the persecution of Antiochus Epiphanes, relates the acts of Judas Maccabæus, and concludes with the defeat of Nicanor, recorded in 1 *Macc.*, vii.

This book is abridged from an earlier work in five books, by one Jason of Cyrene. (2 *Macc.*, ii. 23-32.) The author is unknown, but from the style he is supposed to have been an Hellenistic Jew. It exists in the Greek of the Septuagint, which is considered to be the original, and there are ancient versions in Syriac and Latin. Its authority is greatly inferior to that of the first book, from which it often differs.

The first and second books of Maccabees are received as canonical by the Greek and Roman churches, but not by Protestants. Josephus intimates that they were not reckoned by the Jews as inspired (*Cont. Apion.*, i., § 8), and Jerome says,—'The church does indeed read the books of the Maccabees, but does not receive them among the canonical Scriptures.' (*Præfat. in Prov. Salomonis.*)

3. The *Third Book of the Maccabees* is prior in time to the first and second, and in fact has nothing to do with the history of the Maccabees. It contains the history of the Jews at Alexandria during eight or nine years, from the battle of Raphia, in B.C. 217. The author is unknown. The Greek of the Septuagint is supposed to have been the original. There is a Syriac version in the Paris and London Polyglots, but no ancient Latin version exists. Its canonical authority has been maintained by some of the fathers and by the Greek church; but the Western churches have never received it. In historical value Dr. Cotton places it above the second book, but others esteem it very lightly.

4. The *Fourth Book of the Maccabees* contains an account of the martyrdom of Eleazar and the Seven Brethren (2 *Macc.*, vi., vii.), and of the attempt of Heliodorus to plunder the temple. (2 *Macc.*, iii.) It is found in Greek in the Alexandrian and Vatican MSS., and in some editions of the Septuagint. It is generally supposed to be the same as the treatise of Josephus, 'De Maccabæis,' or 'De Imperio Rationis.' It is praised as a composition by Jerome and Augustin, but it has never been received into the canon.

5. The *Fifth Book of the Maccabees* only exists in Arabic and Syriac. Calmet supposes it to have been written in Hebrew, and thence translated into Greek. It extends from the attempt of Heliodorus to plunder the Temple to within a few years of the birth of Christ. It must have been written after the taking of Jerusalem by Titus, for it refers to that event (chaps. ix. and xxi.). The author is unknown. Some suppose it to have been compiled from the acts of the successive high-priests.

MACCLESFIELD, a market-town and borough, in the county palatine of Cheshire, is situated in the hundred of Macclesfield and parish of Prestbury. Under the Municipal Corporation Act it is divided into six wards, with twelve aldermen and thirty-six councillors. By the Reform Act the townships of Sutton and Hurdsfield were annexed to the parliamentary borough, which sends two members to parliament. The population of Macclesfield in 1801 was 8743; in 1811 it amounted to 12,299; in 1821 to 17,746; and in 1831 to 23,129. The number of inhabited houses in 1831 was 4543; of families, 4740, of whom 4366 were employed in trade and manufactures. Sutton contained 5856 inhabitants, and Hurdsfield 3083. The united population of Macclesfield, Sutton, and Hurdsfield was at that time 32,068, and is now computed to be 40,000. Macclesfield is 166 miles north-north-west from London, and 18 from Manchester.

The son of Henry III., as earl of Chester, made Macclesfield, in 1260, a free borough, consisting of 120 burgesses. Various advantages were afterwards granted to the burgesses by Edward III., Richard II., Edward IV., Elizabeth, and Charles II.

The town of Macclesfield is now the chief seat in the island of the silk-throwing trade, which progressively advanced from 1808 to 1825, when it attained its greatest prosperity. From this prosperity it rapidly declined, and in 1832 there were only forty-one mills at work out of seventy-two. In 1824 not fewer than 10,299 throwsters or spinners were employed: but so many were thrown out of work that the number was reduced to 3622 in 1832. This valuable trade of spinning raw silk flourished in consequence of the protection it received against the introduction of thrown silks from France and Italy. Some notion of the growth of the silk-trade in Macclesfield may be formed, when it is considered that every variety of silk article is now produced in this town, from the narrowest ribbon to the different kinds of sarsnets, plain and figured gros de Naples, satin, silk vestings, and velvets. It is likewise the chief place for the manufacture of silk handkerchiefs of every description, although it suffers from the competition of bandana handkerchiefs from India. This last circumstance, combined with the introduction of the broad silks from the Continent, has reduced wages in Macclesfield more than one-half, and occasionally involves the silk-weavers in the greatest distress

Macclesfield is situated on the west side and at the base of a range of high land which is on the borders of Cheshire and Derbyshire, and is a part of the mountain-region of the latter county. The Bollen, an affluent of the Mersey, runs through the town, the lower part of which is called the Waters. A canal which unites the Grand Trunk and Peak Forest canals passes close to Macclesfield, and thus opens a water communication with most parts of England.

Macclesfield contains four principal streets, diverging from the market-place in various directions; and there are four chief entrances from London, Chester, Manchester, and Buxton. The town-hall is a good building, designed by Goodwin, and decorated with great taste, and the public room is well adapted for concerts and meetings. A subscription library, founded in 1770, contains nearly 20,000 volumes, and is also a depository of the public records. The butchers'-market is a very neat, compact, and suitable range of buildings adjoining the general market. The court-house and gaol for the hundred of Macclesfield are also situated in the market-place. The town is supplied with water conducted in pipes from the adjoining hills, and the money paid for it goes to the borough fund. There are two fire-engines, and the town is lighted with gas. The various factories are situated on the Bollen. One of the cotton-factories cost 30,000*l*, and some of the silk factories 14,000*l*.; but the value of the latter has been much depressed by the deterioration of the silk-trade. The common at the foot of the range of hills on the east side of the town has been enclosed in consequence of an act passed for that purpose in 1791; it is now partly built upon, and the rest highly cultivated. There is an excellent steam-mill for grinding corn in this part of the town. There are two banking establishments, and a branch from the Imperial Bank of Manchester. The corn and butchers' markets take place on Tuesday and Saturday. The fairs for cattle, cloth, toys, &c., are, May 6th, June 22nd, July 11th, October 4th, and November 11.

The dispensary, erected in 1814, has one physician, three honorary surgeons, and one house-surgeon, with a salary of 100*l*. per annum. There is one savings'-bank, eight benefit societies for males, each consisting of 400 or 500 members, and four for females, of about 300 to 400 members each. There are many trusts for charitable purposes. The free grammar-school was endowed with lands in 1502 by Sir John Percyval, sometime lord-mayor of London, who is said to have been born in this city. It afterwards fell into the hands of the crown, and in April 26th, 6th of king Edward VI., a new foundation took place. The annual revenue now amounts to 1300*l*. per annum. By act of parliament (1838) four exhibitions of 50*l*. each for Oxford and Cambridge are established, and a commercial school is to be connected with the grammar-school.

St. Michael's church was founded by Eleanor, queen of Edward I., in 1278. Its architecture is partly Gothic; the chancel end, which has been rebuilt, contains a painted window representing our Saviour, the four Evangelists, and Moses delivering the Ten Commandments. There are two chapels adjoining this church; one belonged to Thomas Savage, archbishop of York, whose heart was buried here in 1508: this chapel now belongs to the marquis of Cholmondeley. The other chapel belongs to the Legh family of Lyme, one of whose ancestors, as appears from a brass plate in it, served king Edward III. and his son the Black Prince, during all their wars in France, and the estate of Lyme was given him for recovering a standard at the battle of Cressy. He afterwards served Richard II., and was beheaded at Chester. Sir Peers, the son of Perkins, served Henry V., and was slain at the battle of Agincourt.

Christ Church was built by Charles Roe, Esq., who acquired a fortune in the silk trade, and was among the first to establish it. The two churches of St. Michael and St. George have sittings for 4500. St. George's church, Sutton, and Trinity church, Hurdsfield, have 1300 seats. There are various meeting-houses belonging to the different classes of Dissenters.

A mechanics' institution was formed a few years ago by one of the principal manufacturers of this town, with the view of encouraging the efforts of some young men who had already been associated for scientific purposes. Various branches of the arts and sciences are now taught to 150 members, and the musical class has made such progress as to treat the town with a concert, which was attended by 1500 persons. When the Factory Commissioners first visited Macclesfield, a census was taken by the manufacturers of the state of education of the children in their employment, and it was found that 96 per cent. could read: the inability of the remaining four parts was accounted for by the circumstance of their belonging to families newly arrived from the country, and their wanting such dress as they thought necessary for appearing at school.

The following was the state of education as ascertained in June, 1838. The whole number of schools was 52, which contained 2109 scholars. Of this number of pupils 1106 also attend Sunday-schools; 1003 frequent only day-schools; 469 are under five years of age, 1586 between five and fifteen, and 54 above fifteen years old. The monitorial system is adopted in only two of the 38 common day-schools, which are attended by 1219 scholars. The number of Sunday-scholars amounts to 7842. Of these 149 are under five years of age, 5716 between five and fifteen, and 1977 are above fifteen. The Established Church has two Sunday-schools and 770 scholars; the union of church and Dissenters 2129, the Wesleyan Methodists three schools and 1175 scholars, Primitive Methodists 585, New Connexion Methodists 1248, Independents 871, Baptists 490, and Catholics 594. The average attendance of children on each Sunday is 5639.

(Corry's *History of Macclesfield*; Ormerod's *History of Cheshire*; Aikin's *Manchester*; *Report on the Silk Trade*, 1832; Charity Commissioners' *Report on the Grammar School*; *Population Returns*; *Communications from Macclesfield*.)

MACE, originally a club of metal, whence it derived its name of Maçe or Maçue, and whence its diminutive Mazuelle is also derived. In a more ornamental form it is used as an ensign of authority borne before magistrates.

The mace as a military weapon was peculiarly appropriated to the cavalry, and in the Bayeux tapestry several are represented in the hands of the combatants. It is not clear when the fashion of suspending them from the saddle-bow for occasional use was first introduced into Europe, but as it seems to have been borrowed from the Asiatics, we may perhaps assign it to the middle of the thirteenth century. Muratori observes that in a close conflict of cavalry it was exceedingly difficult to overthrow or wound powerful men in armour sitting on horseback, for their persons, being enveloped in hauberks, helmets, and other iron coverings, eluded the power of swords, darts, arrows, and such like weapons. For this reason it was usual to strike men so defended with iron maces, or to turn the attack on the horses, that by making them fall they might seize the rider; or if he had tumbled on the ground, the weight of his armour might render him unable to contend with any effect.

Maces seem to have been much used from the time of Edward II., both in battles and tournaments. Meyrick says all the heavy cavalry were supplied with them in the fifteenth and sixteenth centuries, though they sometimes gave way to the short battle-axe and horseman's hammer. The invention of pistols in the reign of Henry VIII. occasioned their disuse in the time of Elizabeth.

Ellis, in his notes to the 'Fabliaux,' says the mace was a common weapon with ecclesiastics, who, in consequence of their tenures, frequently took the field, but were by a canon of the church forbidden to wield the sword. Maces are still used by the Turkish horsemen. (Muratori, *Antiq. Med.*

Rei Militari., 98; Meyrick and Skelton's *Engraved Illustrations of antient Arms and Armour*, 4to., Lond., 1830, vol. ii., pl. 97 and 131; Ellis's *Fabliaux*, edit. 1815, i., 196.)

The word Mace is sometimes used by our old writers in the sense of a *sceptre*.

MACE. [MYRISTICA.]

MACER. A medicinal bark is described in antient authors by this name. Dioscorides states that it is brought from barbarous regions; Galen and Pliny mention it as brought from India; but all agree that it is useful in dysentery. C. d'Acosta describes a tree on the Malabar coast which by the Brachmans is called *Macre*, of which the bark, he says, is used by them as a cure for dysentery, and that Europeans call it the 'arbor sancta,' and St. Thomas's tree. What tree is intended by him his description does not enable botanists to determine, but it might probably be ascertained by those resident on the coast by comparing his description with that of the trees indigenous or much esteemed by the natives of the Malabar coast. Avicenna gives *talisafar* as the Arabic synonyme of *Macer*. Dr. Royle states, in his 'Illustrations of Himalayan Botany,' p. 259, that he obtained from Cabul, under the name of *taleesfur*, leaves of a highly aromatic and stimulant nature, which, having ascertained to be those of a species of Rhododendron, he named *R. aromaticum*, but the plant had been previously called *R. lepidotum* by Dr. Wallich.

In Persian works *makir* is given as the Greek name of *talisfur*. Transcribers no doubt have here, as in the case of Lycium, changed the *k* into *f* by an error of a single point. Though the leaves do not agree with the description of *Macer*, they may long have been substituted for them; they no doubt possess some astringent with their stimulant properties, and are therefore well calculated to be useful as medicinal agents.

MACEDO'NIA (Μακεδονία). The boundaries of this country varied at different times. In the time of Strabo, Macedonia included a considerable part of Illyria and Thrace; but Macedonia Proper may be considered as separated from Thessaly on the south by the Cambunian mountains; from Illyria on the west by the great mountain-chain called Scardus and Bernus, and which under the name of Pindus also separates Thessaly from Epirus; from Mœsia on the north by the mountains called Orbelus and Scomius, which run at right angles to Scardus; and from Thrace on the east by the river Strymon. The Macedonia of Herodotus was however still more limited, as is afterwards mentioned. Macedonia Proper, as defined above, is watered by three rivers of considerable size, the Axius, the Lydias, and the Haliacmon, all which flow into the Thermaic Gulf (the modern Gulf of Salonika). The most easterly as well as the largest of the three, the Axius (*Vardar*), flows from the ranges between Scardus and Orbelus, in the north-west of Macedonia, and is increased by several tributaries, and particularly the Erigon (*Kuchuk Karasou*), which rises in the mountains which divide Macedonia and Illyria. The next river to the west of the Axius is the Lydias (called at the present day *Kara Asmak* on the coast and *Potoco* in the interior), which flowed, according to Strabo (vii., *Extracts*, sec. 9, vol. ii., p. 96, Tauchn.), from the lake on which Pella is situated. It now joins the Axius about a league above the entrance of the Axius into the sea. To the west of the Lydias is the Haliacmon (*Injeh Karasou*), which flows from the Cambunian mountains; in the time of Herodotus it joined the Lydias (vii. 127), but at present the Haliacmon and Lydias enter the sea by different mouths. The whole of the country on the sea-coast, and to a considerable distance in the interior, between the Axius and the Haliacmon, is very low and marshy. [AXIUS.]

From the mountains which divide Illyria and Macedonia two mountain-ranges run towards the south-east, separating the valleys of the Haliacmon, the Lydias, and the Axius: the most southerly of these ranges, which is between the Haliacmon and Lydias, was called Bermius; and the most northerly, between the Lydias and the Axius, Dysorum, in the part of its course at least. The only other rivers of any importance were the Strymon and the Angites, whose valleys were separated from that of the Axius by a range of mountains which runs from Orbelus on the north towards the peninsula of Chalcidice. The Strymon (*Struma*) rises in Mount Scomius and flows into the Strymonic Gulf (*Gulf of Orphano*). Not far from the sea it forms a lake, called Cercinitis (*Kerkinas*), into which the Angites flows from the north. [AMPHIPOLIS.]

P. C., No. 861.

The origin and early history of the Macedonians are involved in much obscurity. Some moderns have attempted, against all probability, to derive the name from the Kittim (כתים) or (כתיים) mentioned in the Old Testament (*Gen.*, x. 4; *Numb.*, xxiv. 24; *Jer.*, ii. 10; *Ezek.*, xxvii. 6; *Dan.*, xi. 30). This opinion appears to have arisen in part from the description of the country inhabited by the Kittim, which is supposed to answer to Macedonia; but still more from the fact that in the book of *Maccabees*, Alexander the Great is said to come from the land of Chettiim (ἐκ τῆς γῆς Χεττιείμ, 1 *Macc.*, i. 1), and *Perseus* is called king of the Kittians (Κιτιέων, 1 *Macc.*, viii. 5).

In inquiring into the early history of the Macedonians, two questions, which are frequently confused, ought to be kept distinct, namely, the origin of the Macedonian people, and the origin of the Macedonian monarchy under the Temenidæ; for while there is abundant reason for believing that the Macedonian princes were descended from an Hellenic race, it appears probable that the Macedonians themselves were an Illyrian people, though the country must also have been inhabited in very early times by many Hellenic tribes. The Greeks themselves always regarded the Macedonians as barbarians, that is, as a people not of Hellenic origin; and the similarity of the manners and customs, as well as the languages, as far as they are known, of the early Macedonians and Illyrians, appear to establish the identity of the two nations. In the time of Herodotus, the name of *Macedonia* comprehended only the country to the south and west of the Lydias, for he observes that Macedonia was separated from Bottiæa by the united mouth of the Lydias and Haliacmon. (Herodot., vii. 127.) How far inland Herodotus conceived that Macedonia extended does not appear from his narrative. According to many antient writers, Macedonia was originally called Emathia (Plin., *H. N.*, iv. 17; Justin, vii. 1; Gell., xiv. 6); but we also find traces of the name of Macedonians from the earliest times, under the antient forms of Macetæ (Μακέται) and Macedni (Μακεδνοί). They appear to have dwelt originally in the south-western part of Macedonia near Mount Pindus. Herodotus says that the Dorians dwelling under Pindus were called Macedonians (i. 56; compare viii. 43); and although it may for many reasons be doubted whether the Macedonians had any particular connection with the Dorians, it may be inferred from the statement of Herodotus that the Macedonians once dwelt at the foot of Pindus, whence they emigrated in a north-easterly direction.

There are various accounts of the origin of the Macedonian monarchy, but all agree in asserting that the royal family was descended from the race of Temenus of Argos. (Herodot., viii. 137-139; Thucyd., ii. 99.) Perdiccas is usually regarded as the founder of this empire; the dominions of which were first confined to the country in the neighbourhood of Edessa between the Lydias and the Haliacmon, but afterwards extended as far as the Axius, and subsequently along the coast as far as the Strymon. Very little however is known of the history of the country till the reign of Amyntas I., who was king of Macedon at the time of the expulsion of the Peisistratidæ from Athens, B.C. 560. This monarch submitted to Megabyzus, who had been left in Europe by Darius after the failure of his Scythian expedition; and Macedonia was considered a province of the Persian empire till the battle of Platæa delivered it from subjection to the king of Persia.

Amyntas was succeeded by his son Alexander I., who was obliged to accompany the Persian army into Greece, but was able on several occasions to render important services to the Grecian cause. Alexander was not allowed to contend at the Olympian games until he had proved his Argive descent. (Herodot., v. 22; compare Justin, vii. 2.) The time of Alexander's death is uncertain, but he lived at least to B.C. 463, when Cimon recovered Thasus. (Plutarch, *Cimon*, c. 14.) He was succeeded by Perdiccas II., a fickle and dishonourable prince, who took an active part in the Peloponnesian war and alternately assisted Athens and Sparta as his interests or policy dictated. His successor Archelaus (B.C. 413) was the wisest monarch that had yet sat upon the throne of Macedon. He effected greater improvements in his kingdom, according to Thucydides, than all the other monarchs together who had preceded him (ii. 100). He greatly improved the condition of his army, he erected forts to repress his barbarous neighbours, constructed roads, and endeavoured to diffuse among his subjects a love of Grecian literature and refinement. He is said to have invited Socrates to settle at his court, and Euripides resided there during the latter period of his life. [ARCHELAUS.]

On the assassination of Archelaus, B.C. 399, the greatest confusion prevailed for many years; and it was not till the accession of Amyntas II. (B.C. 393), that anything like order was restored to the country. But even during the greater part of his reign Macedonia was distracted by intestine commotions and foreign enemies; and on his death, B.C. 369, the same state of confusion prevailed that had followed the death of Archelaus. Amyntas was succeeded by his oldest son, Alexander II., who was assassinated at the end of the first year of his reign by Ptolemy Alorites, who held the supreme power for three years as regent during the minority of Perdiccas; but, in consequence of abusing his trust, he was cut off by Perdiccas, B.C. 364. Perdiccas, after a reign of five years, fell in battle against the Illyrians, B.C. 359, and was succeeded by his younger brother, the celebrated Philip, who succeeded to a kingdom assailed by numerous enemies and weakened by intestine commotions, and left it, to his son Alexander the Great, the most powerful monarchy in Europe. [PHILIP; ALEXANDER.] The immediate consequences of Alexander's death are given under ANTIPATER and CASSANDER; it may be sufficient to state here, that in the commotions consequent upon that event, the royal family was finally destroyed, and Cassander obtained at first the power, and eventually the title of king of Macedon. Cassander was succeeded by his son Philip, B.C. 296, who reigned only two years; and on his death, in B.C. 294, his two younger brothers, Antipater and Alexander, having quarrelled respecting the succession, the throne was seized by Demetrius, the son of Antigonus, who reigned for seven years. He was driven from his kingdom, B.C. 287, by Pyrrhus, king of Epirus, who was however deposed in his turn, after a short reign of seven months, by Lysimachus, king of Thrace. [LYSIMACHUS.]

On the death of Lysimachus, who fell in battle, B.C. 281, the country remained in almost a state of anarchy for many years. The invasion of the Gauls from B.C. 280 to B.C. 278, and the contests between the numerous pretenders to the throne, brought the country to the brink of ruin. Eventually Antigonus (surnamed Gonnatas), the son of Demetrius, was proclaimed king; but was dethroned by Pyrrhus, who again obtained the kingdom on his return from Italy. After the death of Pyrrhus, Antigonus regained possession of the throne, which he retained till his death, B.C. 239. The two following monarchs, Demetrius II. (B.C. 239-229) and Antigonus II. (B.C. 229-220), were principally occupied in the Grecian wars which followed the formation of the Achæan league. [ANTIGONUS.]

Philip V., who succeeded Amyntas, alarmed at the increasing power of the Romans, entered into an alliance with Hannibal; but was never able to afford him any effectual assistance, in consequence of continual wars with the Ætolians and Illyrians, whom the Romans had found means to excite against him. On the conclusion of the war with Carthage, Philip found that he was unable to cope with the Roman power; and after continuing the contest for a few years, was obliged to sue for peace on such terms as the victors chose to grant. Philip was succeeded by Perseus, B.C. 178, who carried on war against the Romans, and was finally conquered, B.C. 168. [ÆMILII.] Macedonia was not immediately converted into a Roman province, but was divided into four districts, which were considered independent, and governed by their own laws, and of which the capitals were respectively—Amphipolis, Thessalonica, Pella, and Pelagonia. Macedonia was reduced to the form of a Roman province, B.C. 142.

It is very difficult to determine the boundaries of the Roman province of Macedonia. According to the 'Epitomizer' of Strabo (vii.), it was bounded by the Adriatic on the west; on the north by the mountains of Scardus, Orbelus, Rhodope, and Hæmus; on the south by the Via Egnatia; and on the east it extended as far as Cypsela and the mouth of the Hebrus. But this statement with respect to the southern boundary of Macedonia cannot be correct, since we know that the province of Macedonia was bounded on the south by that of Achæa; and although it is extremely difficult, if not impossible, to fix the precise boundaries of these provinces, yet it does not appear that Achæa extended further north than the south of Thessaly.

Macedonia was inhabited from the earliest times by numerous tribes, whose names continued to be given till a late period to various districts of the country. The [illegible] important of these divisions were—Mygdonia, Bottiæis [illegible] Bottiæa, Pieria, Elimea, Stymphalia, Orestis, Ly[illegible] Eordia or Eordæa, Emathia, Pæonia, and Chalcidice.

Mygdonia, on the Thermaic Bay, was separated [illegible] the district of Bottiæis, or Bottiæa, by the Axius (He[illegible] dot., vii. 123); but its boundaries on the east are [illegible] ful. Thucydides makes it extend as far as the Stry[illegible] (ii. 99); but this is at variance with the statement [illegible] Herodotus, who speaks of the land to the west [illegible] Strymon under the name of Bisaltia. (Herodot., [illegible]) Mygdonia was originally occupied by the Edones, a T[illegible] cian people, who were expelled thence by the Temen[illegible] (Thucyd., ii. 99.) The principal town in this district [illegible] Therme, afterwards called Thessalonica by Cassander [illegible] honour of his wife, who was daughter of Philip. ([illegible] vii., *Excerpta*, sec. 10, vol. ii., p. 131.) It was a large [illegible] prosperous town, and exists at the present day under [illegible] name of Saloniki. The Apostle Paul addressed two [illegible] to the Christian converts in this town. The lake B[illegible] called at the present day Betchik, was either in or [illegible] Mygdonia (Thucyd., i. 58); it is said by Dr. Clarke [illegible] about twelve miles in length, and six or eight in breadth.

The Bottiæis, or Bottiæa of Herodotus, was bounded [illegible] the east by the Axius, on the west by the united [illegible] the Haliacmon and Lydias (vii. 127), and on the north [illegible] Emathia.* The principal town of Bottiæis was P[illegible] situate on the lake through which the Lydias flows, [illegible] afterwards became the residence of the kings of Mac[illegible] Pella was a small place till the time of Philip, by wh[illegible] was greatly enlarged and beautified. (Strabo, [illegible] vol. ii., pp. 130-131.) The ruins of Pella may still [illegible] at Alakilisseh. Near the mouth of the Lydias was t[illegible] of Ichnæ, celebrated for an antient temple. (Her[illegible] 123; Pliny, *H. N.*, iv. 17; Mela, ii. 3; Hesych[illegible] Ἰχναίην.) Thirty miles to the south of Pella, at t[illegible] Mount Bermius (Plin., *H. N.*, iv. 17), was the [illegible] of Berrhœa, or Berœa, which is mentioned in the *Acts* [illegible] *Apostles* (xvii. 10).

Proceeding along the coast we come to Pieria. T[illegible] antient district of Macedonia originally intervened be[illegible] Bottiæa and Pieria. According to Strabo (vii., sec. 8, [illegible] p. 130), and Livy (xliv. 9), Pieria was bounded on [illegible] by Dium; but in more antient times the name was [illegible] applied to all the country between Macedonia and the P[illegible] Ptolemy calls the country between the mouth of the [illegible] and that of the Peneus by the name of Pieria. Pi[illegible] celebrated in Grecian mythology as the first se[illegible] muses. Pydna, the chief place in this district, a[illegible] Cydna (Steph. Byz.), and Citron, according to S[illegible] sec. 8, vol. ii., p. 130), known at the present day [illegible] name of Kidros, is said to have been a Greek city, a[illegible] for some time in possession of the Athenians. [illegible] afterwards taken by Philip and given to Olynth[illegible] battle between Perseus and Æmilius, which decide[illegible] of the Macedonian monarchy, was fought near P[illegible] South of Pydna was the town of Dium, at the f[illegible] Olympus, of which Livy has given a short descr[illegible] 6, 7). It afterwards became a Roman colony [illegible] *H. N.*, iv. 17.) Forty stadia to the north of Py[illegible] Methone (Strabo, vii., sec. 8, vol. ii., p. 130), at t[illegible] which Philip, the father of Alexander the Great, [illegible]

In the interior, to the west of Pieria, in the [illegible] Haliacmon, was the district of Elimea, the inh[illegible] which were called Elimiotæ. In the time of T[illegible] Elimea was subject to the Macedonian monar[illegible] governed by its own princes (ii. 99). There was a [illegible] from Elimea to Thessaly over the Cambunian m[illegible] (Liv., xlii. 53), and another to Ætolia (Liv., xliii [illegible]

South-west of Elimea was the district of St[illegible] which was annexed to Macedon on the conquest of [illegible] by the Romans (Liv., xlv. 30), together with the [illegible] the Atintani and Paravæi, which extended to the [illegible] Elimea, in Illyria and Epirus.

North-west of Elimea was the district of Orest[illegible] xviii. 30; Liv., xxxiii. 34), which probably derived its [illegible] as Müller has remarked, from the mountains [illegible] the country (ὄρος, *mountain*), and not from Orest[illegible] of Agamemnon. The Orestæ appear to have be[illegible] pendent of the Macedonian kings for a considera[illegible] they were however obliged at length to submit to their authority, but were declared independent again on the conquest of Macedonia by the Romans. (Liv., xxxiii. 34.) The principal town in this district was Celetrum, situate on a peninsula which ran into a lake of the same name (the modern *Kastoria* or *Kesrie*).

---

* The Bottiæa of Thucydides is a different country, being a part [illegible] the Isthmus, to the east of Potidæa and the west of Torone, after [illegible] driven out of Bottiæa. ([illegible] Journal of Education, [illegible])

Lyncus, the country of the Lyncestæ (Thucyd., iv. 83, 124; Liv., xxvi. 25; xxxi. 33; xxxii. 9), north of Orestis, was surrounded by mountains on all sides. It contained no towns of any importance except Heraclea, which was situated on the great Egnatian road. The Lyncestæ were governed by an independent prince of the name of Arrhibæus during the early part of the Peloponnesian war. (Thucyd., iv. 124.)

To the east of Lyncus, and north of Elimea and the Bottiæa, was the district of Eordia, or Eordæa, in the valley of the Lydias. The Eordians are said to have been driven out of their country, which however still continued to bear the name of Eordia, by the Temenidæ, and to have settled afterwards about Physca, which was probably a town in Mygdonia. (Thucyd., ii. 99.)

Emathia, which was afterwards limited to the country north of Bottiæa, in the valley of the Lydias, was the name, as has been already remarked, by which the country was originally called, according to many ancient writers. The chief town in this district, *Ægæ*, afterwards called Edessa (*Vodena*), was the capital of the Macedonian kingdom in the earliest times; and even when it had ceased to be the royal residence, it still continued the burial-place of the kings. It was a large city in the time of Livy (xlv. 30). It stood on the Via Egnatia, 30 miles west of Pella.

The northern part of Macedonia was inhabited by various tribes of Pæonians; of which the principal were the Pelagonians, who dwelt north of Lyncestis. The chief town of the district was also called Pelagonia. The Agrianes, north-east of the Pelagonians, were a powerful Pæonian tribe, living near the sources of the Strymon (Strabo, vii., c. 18, vol. ii., p. 122.)

The peninsula south of Mygdonia, between the Thermaic and Strymonic gulfs, was called Chalcidice from the Chalcidians of Eubœa, who formed settlements in this country at very early times. The peninsula of Chalcidice comprised in the south three smaller peninsulas: Pallene, formerly called Phlegra (Strabo, vii., c. 12, vol. ii., p. 121), between the Thermaic and Toronaic gulfs; Sithonia, between the Toronaic and Singitic gulfs; and Actê, as Thucydides calls it (iv. 109), or Athos, according to Herodotus (vii. 22), between the Singitic and Strymonic gulfs. [ATHOS.] The peninsula of Chalcidice, together with the three smaller peninsulas, contained several important towns, which are frequently mentioned in Grecian history.

Potidæa, afterwards called Cassandria from Cassander, king of Macedon, founded by the Corinthians (Thucyd., i. 56), stood on the narrow isthmus which connects the peninsula of Pallene with the mainland. It sent 300 men to Platæa (Herodot., ix. 28), and after the Persian war was subject to the Athenians. Potidæa revolted from Athens, B.C. 432; and was not taken till after a siege of two years; when the Potidæans surrendered and were allowed to quit the place. A mutilated inscription in elegiac verse, now in the British Museum, commemorates the courage of those Athenians who fell in a battle before this town, B.C. 432 (*Elgin Marbles*, No. 345.) An Athenian colony was afterwards sent to occupy the town. (Thucyd., ii. 70.) It subsequently fell under the power of Philip of Macedon, and continued from that time subject to the Macedonian kings. The other towns of Pallene were Aphytis, with a celebrated temple of Bacchus; Mende, a colony of Eretria in Eubœa (Thucyd., iv. 123), which revolted from the Athenians, B.C. 423, and was retaken by Nicias and Nicostratus; and Scione, said to have been founded by the Pellenians from Achaia in Peloponnesus, which also revolted from the Athenians, B.C. 423, but was retaken, and the inhabitants treated with great cruelty; the town and lands were afterwards given to the Platæans. (Thucyd., v. 32.)

At the head of the Toronaic Gulf was the important town of Olynthus, founded by the Chalcidians and Eretrians of Eubœa. [OLYNTHUS.] The chief town in Sithonia was Torone, on the south-western coast, which was also probably founded by the Eubœans. Torone was for a long time subject to the Athenians, but afterwards belonged to the Olynthian confederacy, and was eventually united to the Macedonian monarchy by Philip.

The peninsula of *Actê*, or *Athos*, was inhabited in the time of Thucydides by a few people of Chalcidic origin, but principally by Pelasgians, Bisaltæ, Crestonians, and Edonians, who dwelt in small fortified villages. (Thucyd., iv. 109.) At the extremity of this peninsula was Mount Athos, called at the present day *Monte Santo*. The canal of Xerxes can still be distinctly traced. Herodotus enumerates six towns within this peninsula: Sane, founded by the inhabitants of Andros (Thucyd., iv. 109); Dium, Olophyxus, Acrothoon, Thyssus, and Cleonæ. Acanthus, situate on the low flat isthmus which connects the peninsula of Actê with the mainland, was once an important town. [ATHOS.] The chief towns in the interior of the peninsula of Chalcidice were Chalcis and Apollonia, mentioned in the *Acts of the Apostles* (xvii. 1).

The Via Egnatia, which formed one great line of communication between the Ionian Sea and Byzantium, commenced at Apollonia in Illyria, and was joined at Clodiana on the Genusus by the Via Candavia, from Dyrrhachium, which however is also called the Via Egnatia (Strabo, vii. § 4). The Via Egnatia entered Macedonia in the district of Lyncus, and passed by the towns of Edessa, Pella, Thessalonica, Apollonia, and Amphipolis, where it entered Thrace. [THRACE.]

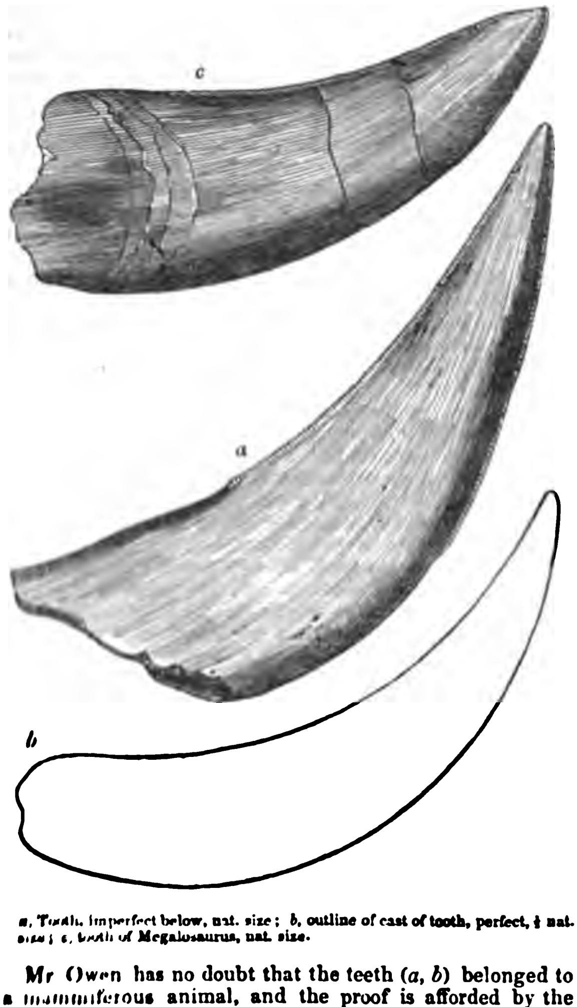
MACERA'TA E CAMERI'NO, DELEGAZIONE DI, a province of the Papal State, forming part of the old division called the Marches, is bounded on the north by the provinces of Ancona and Urbino e Pesaro, on the east by the Adriatic, on the west by the province of Perugia, and on the south by those of Spoleto and Fermo ed Ascoli. Its population amounts to 243,000 inhabitants, distributed among 12 walled towns, or *terre* with communal councils, and 235 villages and hamlets. The general inclination of the surface of the country is to the north-east, as it spreads from the foot of the central Apennine chain to the coast of the Adriatic. The principal rivers are the Potenza, Chienti, and Musone, which rise in the Apennines and flow into the Adriatic.

The principal towns are: 1, Macerata, on a hill in a fine country watered by the Chienti, a neat, well-built, cheerful town, with 15,000 inhabitants, several churches and convents with good paintings, a college, and a university, with a library containing 20,000 volumes, a court of appeal for all the provinces of the Marches, a handsome town-house, and several fine private palaces, amongst which the Palace Compagnoni is the most remarkable. Macerata is a bishop's see and the residence of the delegate. It carries on a considerable trade in corn, silk, and cattle. An annual fair for horses is held at Macerata. 2, LORETO. 3, Recanati, near the Adriatic, with 4000 inhabitants, and several churches and convents. 4, Tolentino, farther inland, near the foot of the Apennines, with 3000 inhabitants, and known in modern history for the treaty of peace of February, 1797, between General Bonaparte and Pope Pius VI.; and also for a battle on the 3rd of May, 1815, between the Austrians under General Bianchi and the Neapolitans under Joachim Murat, which by the defeat of the latter decided the fate of Naples. 5, Camerino, the ancient Camerinum, an old town among the Apennines, and a bishop's see, with 7000 inhabitants, several churches and convents, and some silk manufactories. It is the birth-place of the painter Carlo Maratti. 6, Fabriano, farther north, a bishop's see, with 7000 inhabitants, manufactories of paper and parchment, and a considerable trade in wool. 7, S. Severino, with 3000 inhabitants. 8, Matelica, an old town, with 3000 inhabitants.

The province of Macerata is in part very mountainous and barren, but the valleys and plains towards the sea-coast produce abundance of corn, wine, most kinds of fruit, and very good silk. The coast along the Adriatic has no harbour which deserves the name. Recanati has a kind of port or anchoring-place for small vessels at the mouth of the river Potenza, where some trade is carried on. (Calindri's *Saggio Statistico*; Neigebaur.)

MACERATION is the exposing of any substances, and generally those of vegetable origin, when reduced to coarse powder, to the action of water or any other liquid, without the assistance of heat, in which last circumstance it differs from digestion. The object of maceration is twofold: either merely to soften the parts of the substance operated on, so as to allow of the more ready subsequent action of heat, as when cinnamon or cloves are macerated in water, previously to distillation; or it is employed to dissolve the aromatic parts of a substance, when digestion would not merely dissolve but dissipate them.

MACHA'IRODUS, a genus of extinct animals established by Professor Kaup upon those canine teeth with serrated or dentilated edges which have been attributed to bears (*Ursus cultridens*, &c.) by Cuvier and others, and to great cats (*Felis*) by Bravard. Dr. Buckland (*Bridgewater Treatise*), in his catalogue of the animal remains found in strata of sand, referrible to the second period of the tertiary formations (Miocene of Lyell), at Epplesheim near Altzey, about twelve leagues to the south of Mayence, and recorded by Kaup, includes *Machairodus*, which Dr. Buckland places between *Felis* and *Gulo*, and notes as 'allied to bear, *Ursus cultridens*.' Professor Kaup however remarks, that these 'canine teeth' and even the dentilations on their edges have a complete resemblance to those of *Megalosaurus*, and indeed their flatness and thinness do not correspond with the canine teeth of any of the existing *Carnivora*, while the dentilations strongly resemble those of the Saurian above mentioned. We here figure a tooth of *Megalosaurus*, a tooth of *Machairodus* (*Ursus cultridens*) and a cast of another, from specimens in the museum of the Geological Society of London.



a, Tooth, imperfect below, nat. size; *b*, outline of cast of tooth, perfect, ½ nat. size; *c*, tooth of Megalosaurus, nat. size.

Mr Owen has no doubt that the teeth (*a*, *b*) belonged to a mammiferous animal, and the proof is afforded by the cast (*b*), which shows that the tooth was originally lodged in a socket, and not anchylosed to the substance of the jaw, and that the fang is contracted and solidified by the progressive diminution of a temporary formative pulp, and does not terminate in an open conical cavity like the teeth of all known Saurians, which are lodged in sockets. Careful comparison will show that the canine teeth of Machairodus are very far from those of the bears, and sufficiently removed from those of the tiger, though those of the latter present serrated edges. On looking at the catalogue of the extinct species found at Epplesheim, we do not find any large fossil ruminant noticed, though we find large cats, some as large on, and another carnivorous animal (*Agnotherium*) to the dog and also as large as a lion · and we are not without existing ruminants with very long canine teeth in the upper jaw with serrations on their edges, though not so broad in proportion as those of *Machairodus*. [BEAR, vol. iv., p. 95.]

MACHE'TES, Cuvier's name for the Ruff (*Tringa pugnax*, Linn.). [SCOLOPACIDÆ.]

MACHIAVE'LLI, NICCOLO', was born at Florence in 1469, of an old though not wealthy family of that republic. Having received a liberal education, he was employed in the office of Marcello Adriani, chancellor of the community of Florence, and afterwards, when twenty-nine years of age, he was made secretary of the 'Ten,' a board entrusted with the management of foreign affairs and diplomatic negotiations. Machiavelli's abilities and penetration being soon perceived by his superiors, he was successively employed on many and some very important missions. The first was in 1498, to Jacopo Appiani, lord of Piombino, for the purpose of engaging him to join the Florentine troops which were besieging Pisa, whilst their general Vitelli was defending the Florentine territory against the Venetians, who, joined to the emigrant partisans of the Medici, were making incursions from the borders of Romagna. In the following year, 1799, Machiavelli was sent to Catherine Sforza, countess of Forli, in order to make arrangements with her son Ottaviano to engage as a condottiero in the service of the republic. The instructions given by the Ten to Machiavelli for each of his missions. and his letters or reports to them written during the course of his negotiations, have been published, at least in great part, and they occupy volumes iv. and v. of the 4to. edition of his works (Florence, 1782). They are most curious and valuable documents for the history of the times, and they are also most useful for the understanding of Machiavelli's political and historical works which he wrote later in life. Many letters however, and some of great importance, written to or by Machiavelli, remain still inedited. There is a collection of them in the hands of M. S. at Paris; three more volumes of autographs were purchased in 1826, at Florence, by Lord Guilford; and another part remains at Florence in the libraries Pitti, Rinuccini, and others. (Valéry, *Voyages en Italie;* Avenel, three articles on the French translation of the works of Machiavelli by Périès, which appeared in vols. 41 and 42 of the *Révue Encyclopédique.*)

In the year 1500 Machiavelli was sent as a commissioner to the Florentine camp before Pisa. He was present at the arrival of a body of French and Swiss auxiliary troops under De Beaumont, sent by Louis XII., who had just reconquered Lombardy and had formed an alliance with Florence. Dissensions however arose between the allies concerning the pay of the auxiliaries. The Swiss mutinied, and insulted Luca degli Albizzi, one of the Florentine commissioners; and the French abandoned the attack against Pisa, throwing all the blame upon the Florentines, and took possession of Pietrasanta, of Massa and Carrara, and other districts belonging either to Florence or its allies. This was an anxious period for Florence, which saw itself entirely at the mercy of France, while it was threatened on the other side by Cesare Borgia, then the terror of central Italy, who, supported by his father Pope Alexander VI., and also by the French, was making himself master of Romagna by force and treachery, and threatening Florence, where he wished to re-establish the Medici. [BORGIA, CESARE.] In July, 1500, Machiavelli was despatched to France in order to explain to Louis XII. the untoward occurrences at Pisa, to endeavour to keep the king, or rather his all-powerful minister Cardinal d'Amboise, archbishop of Rouen, in a friendly disposition towards Florence, and thus screen the republic from the ambition of Borgia. This was a very delicate mission. The French king and minister were prejudiced against the Florentines; they had an interest in favouring the Borgias, and they were also instigated against Florence by Trivulzio, Beaumont, and other persons of influence at the French court. Machiavelli's mission to France lasted till January, 1501. He followed the French court to Melun, Blois, Nantes, and other places, and by dint of much skilful management, of fair promises and professions, and of timely suggestions, he left Louis better disposed towards Florence than he had found him, and made him watchful and jealous of the movements of Cesare Borgia. This jealousy of the French king proved the salvation of the republic a few months after, when the ferocious and unprincipled Borgia entered Tuscany with 8000 men, and encamped a few miles from Florence. The citizens showed firmness, and in the meantime letters came from the French king forbidding Borgia from molesting the republic. A convention was concluded in May, 1501, between Florence and Borgia, by which the latter, after receiving a sum of money, went his way to Piombino, and left the Florentine territory after committing many depredations. But in the following year Borgia, having returned to Romagna, drove away Guidobaldo, duke of Urbino, and took possession of Camerino, whose lord, Giulio Varano, he caused to be strangled with his three young sons, while his subordinate Vitellozzo Vitelli supported the revolt of Arezzo, Cortona, the Val di Chiana and other districts against Florence, and in favour of the Medici. Here again the French interfered, and Vitelli, who began to be alarmed at the cruelty of Borgia, entered into an agreement with the French and with Florence, by which Arezzo and other towns were restored in August, 1502. On this occasion Machiavelli, being requested by the government, wrote his opinion concerning the manner in which the revolted districts ought to be treated: 'Sul modo di trattare i popoli di Val di Chiana.' Quoting the opinion of L. Furius Camillus after the subjugation of Latium, and the conduct of the Roman senate towards the Latin cities, he advised moderation in the present instance, except towards Arezzo, which he compared to Velitræ, and advised to be treated accordingly. (Livy, viii.)

In September of the same year, 1502, the Florentines, alarmed at the dangers by which they were encompassed, saw the necessity of giving greater stability to their executive, by appointing a gonfaloniere perpetuo, a kind of dictator for life. They chose for this office Piero Soderini, a man upright and disinterested, and without children, and therefore less likely to excite suspicions or jealousy. About the same time Machiavelli was sent on a mission to Duke Valentino, the formidable Borgia, who was then at Imola in Romagna. Borgia had just returned from Lombardy, from an interview with Louis XII., in which he endeavoured to clear himself from the charge of having countenanced the insurrection against Florence, and moreover to obtain assistance from the French king for the purpose of subduing Bologna, which he intended to make the capital of his duchy.

During his absence in Lombardy, his own friends and former colleagues, Vitellozzo Vitelli, Baglioni of Perugia, the Orsini, and Oliverotto da Fermo, alarmed at the increasing ambition and cruelty of Borgia, determined to forsake him, and entered into a secret league with Bentivoglio of Bologna and Petrucci of Siena, who were his declared enemies. At the same time they invited the Florentines to join them. But as Borgia was protected by France, whose displeasure the Florentines were afraid of incurring, they sent Machiavelli to make professions of friendship to Borgia, and at the same time to watch his movements, to discover his real intentions (which was not an easy thing, for Borgia was the closest man of the age), and to obtain something in return for their friendship. The account of this mission is extremely curious: there was deep dissimulation on both sides: Borgia hated Florence as much as the Florentines hated him; but they were both kept in check by the fear of France, and both Borgia and Machiavelli made the fairest and apparently most candid professions towards each other. Borgia even assumed a confidential tone, and began to tell Machiavelli of the treachery of his former friends; he added that he knew how to deal with them, and was only waiting for his own time; he also expatiated on his well-disciplined forces, his artillery, and the assistance he expected from France; and all this in order to persuade the Florentines of the great value of his friendship, and that they should give him a condotta, that is to say, the chief command in their army. Borgia however had to do with a negotiator who, though young, was a match for him. 'I answered,' says Machiavelli in the 21st letter of that mission, 'that his excellency the duke must not be compared to the generality of other Italian lords, but that he must be considered as a new potentate in Italy, with whom it is more fit and becoming to make a treaty of alliance than a mere condotta or mercenary convention. And I added, that as alliances are maintained by arms, which are the only binding security for either party, your lordships (the magistrates of Florence) could not see what security there would be for them if three-fourths or three-fifths of your forces were to be in the hands of the duke.' Still the negotiations went on about the condotta, whilst Borgia was meditating another stroke of his usual policy. Machiavelli had a foretaste of it at Cesena, where a certain Ramiro, a confidential agent of Borgia, and, as such, hateful to the people, was suddenly arrested by order of his master, and the next morning (on the 26th of December) was found in the middle of the square cut into two pieces; 'Such,' says Machiavelli, 'has been the duke's pleasure, for he wishes to shew that he can do and undo his own men as he thinks proper.' On the last day of December, Borgia, followed by Machiavelli, marched with his troops to Sinigaglia, where the Orsini, Vitellozzo, and Oliverotto were waiting for him, to have a conference and settle matters. As soon as his troops had entered the town he arrested these chiefs, strangled two of them that very night, and kept the Orsini in prison until he heard that his father, the pope, had secured the person of their relative Cardinal Orsini at Rome, after which they also were put to death. On that very night Borgia sent for Machiavelli, and said that he had done a great service to Florence in ridding the world of those men who were the sowers of discord. He then expressed his wish to attack Siena and revenge himself on Petrucci; but the Florentines, being cautioned by Machiavelli, took measures to thwart his plans, and Petrucci was saved. Machiavelli returned to Florence in January, 1503, after three eventful months passed in the court and camp of Borgia, which was the most complete school of that policy which he afterwards illustrated in his treatise 'Del Principe.' His letters (fifty-two in number) written during that mission have a certain dramatic character which awakens feelings of surprise, terror, and intense curiosity. Machiavelli wrote also a detached report of the Sinigaglia tragedy: 'Descrizione del modo tenuto dal Duca Valentino per ammazzare Vitellozzo Vitelli, Oliverotto da Fermo, il Sigr. Pagolo e il Duca di Gravina Orsini.' He obtained one thing from Borgia by this mission, a free passage through Romagna to all Florentine travellers and merchants, and their goods and other property. This document is headed 'Cæsar Borgia de Francia, Dei gratia Dux Romandiolæ, Valentiæque, Princeps Hadriæ et Venafri, Dominus Plumbini, &c., ac Sanctæ Romanæ Ecclesiæ Confalonerius et Capitaneus Generalis,' and dated 'Imolæ, 19 Octobris, A.D. 1502. Ducatus vero nostri Romandiolæ secundo.'

In August of that same year, 1503, Alexander VI. died, and his successor, Pius III., died a few days after. A new conclave being assembled in October, the Florentines sent Machiavelli to Rome, where he was present at the election of Julius II., and soon after witnessed the fall of Cesare Borgia, who was arrested at Ostia by order of the pope, and all his ill-gotten dominions were taken from him. His troops, in passing through Tuscany, were disarmed and disbanded agreeably to Machiavelli's secret advice.

In January, 1504, Machiavelli was sent to France to rouse Louis XII. to the danger threatening both Florence and the state of Milan from the Spaniards, who were advancing from Naples towards North Italy. The truce between France and Spain put an end to this mission.

After several minor missions to Piombino, to Baglioni of Perugia, Petrucci of Siena, and the duke of Mantua, Machiavelli was sent, in August, 1506, to Pope Julius II., whom he met on his march to dispossess Baglioni of Perugia and Bentivoglio of Bologna, whither the Florentine envoy followed him, and returned in October. (*Opere di Machiavelli: Legazione seconda alla Corte di Roma.*) He then wrote 'Provvisione per istituire Milizie Nazionali nella Republica Fiorentina.' He had always blamed the employment of mercenary troops and condottieri, which was an old custom of the Florentines.

In December, 1507, Machiavelli was sent to the emperor Maximilian in Germany, who had signified his intention of going to Italy to be crowned, and had demanded money of the Florentines. He proceeded by Geneva and Constance, where, finding that the emperor had moved southwards by the Tyrol, he followed him to Bolzano. The Venetians however opposed the passage of Maximilian, and Machiavelli returned to Florence in June, 1508. On his return he wrote several reports on the affairs of Germany, besides the letters which he had sent home during his mission: 'Rapporto sulle cose di La Magna;' 'Discorso sopra le cose dell' Alemagna;' 'Ritratti di Lamagna.'

In February, 1509, he was sent to the camp before Pisa, which was again besieged by the Florentines, and he thence addressed a report on the state of affairs: 'Discorso fatto al Magistrato dei Dieci sulle cose di Pisa.' In June of that year Pisa surrendered, through famine

In July, 1510, Machiavelli was sent to France a third time. The Cardinal d'Amboise was lately dead. The object of this mission was to encourage the French court to maintain the alliance with the pope and the emperor against the Venetians (the league of Cambrai), and to induce Louis to prevent the Swiss from enlisting in great numbers in the service of the pope, for fear that Julius, feeling himself independent, should take some new whim into his head. And this in reality happened soon after; for, while Machiavelli was in France, Julius formed a league to drive the French out of Italy. The letters of this mission are very important. The audiences of Louis to Machiavelli, and the conferences of the latter with the cardinal of Paris, the chancellor of France, and others, and his reflections on the pope, on the projects of Louis, on the proposal made by the emperor Maximilian to Louis, of dividing Italy between them, which Louis refused to accede to, are extremely interesting. Machiavelli returned to Florence in September, 1510, having consolidated the alliance of Florence with France.

On his return he wrote his second 'Decennale,' or short chronicle, in terza rima. The first 'Decennale' went as far as 1504, after the fall of the Borgias. It thus alludes satirically to the death of Alexander VI.:—

'Malò Valenza; e per aver riposo
Portato fù frà l'anime beate,
Lo spirto d'Alessandro glorioso.
Del qual seguirno le sante pedate
Trè sue famigliari e care ancelle,
Lussuria, simonia, e crudeltade.'

The second 'Decennale' comes down only to the year 1510, but Machiavelli intended to complete it till 1514. In September, 1511, he was sent again to France, concerning the council which assembled at Pisa, by order of Louis XII., to try and depose Pope Julius, which council however broke up without effecting anything. Machiavelli fell ill, and soon returned home. In 1512 the battle of Ravenna was fought, Gaston de Foix was killed, and the French lost Italy. Julius, who was irritated against Florence for having sided with the French, engaged the Spanish viceroy of Naples to send a body of troops against it, and re-establish the Medici by force. The catastrophe took place soon after.

In September, 1512, when Giuliano and Giovanni de' Medici, the sons of Lorenzo, re-entered Florence by means of the Spanish infantry, and overthrew the popular government, the gonfalonière Soderini made his escape, and the secretary Machiavelli, with others of the popular party, was dismissed from office, and banished for a time from the city. In the following year a conspiracy was discovered against the Medici, in which Machiavelli was accused of having participated; being arrested in February, 1513, he was put to the torture, which was the usual means then employed under all the governments of Florence and of Italy, of examining persons accused of state crimes. He however maintained that he had nothing to confess. From his prison of Le Stinche he wrote a sonnet to Giuliano de' Medici, who was then governor of Florence, his brother Giovanni having gone to the conclave at Rome, where he was elected pope by the name of Leo X. The sonnet, which is half sad, half humorous, describing his sufferings, his own torture, the annoyance of hearing the screams of the other prisoners, and the threats he had of being hanged, is given by Artaud in his biography, entitled 'Machiavel, son Génie et ses Erreurs,' 2 vols. 8vo., Paris, 1833.

He was soon after released, in consequence of a pardon sent from Rome by Leo X. to all those concerned in the conspiracy. Before however the pardon arrived, two of them, Pietro Boscoli and Agostino Capponi, had been executed.

Machiavelli now withdrew for several years from public life, and retired to his country-house at San Casciano, about eight miles from Florence. During this retirement he wrote his discources upon Livy his books on the art of war, and his 'Principe.' The last work has been the subject of much controversy, which is now at an end. The book 'Del Principe,' or 'De Principatibus,' for that was the original title, was not intended for publication; it was written by the author for the private perusal first of Giuliano, and then of Lorenzo de' Medici, afterwards duke of Urbino, son of Piero and grandson of Lorenzo the Magnificent, who was appointed by Leo X. governor of Florence, his uncle Giuliano having removed to Rome.

Machiavelli, in a letter discovered only in 1810, and addressed to his friend Vettori, then at Rome, 10th December, 1513, after humorously describing his mode of life in the country, mentions this treatise on which he was then engaged, and tells him that he wishes to show to the Medici 'that he had not spent the 15 years in which he had studied the art of government in sleeping or playing, so that they might think of employing a man who had acquired experience at the expense of others;' and he adds, 'I wish that these signori Medici would employ me, were it only in rolling a stone. They ought not to doubt my fidelity. My poverty is a testimony of it.' These expressions show clearly enough that Machiavelli's object in writing the 'Principe' was to recommend himself to the Medici. All the ingenious surmises of later critics about his wishing to render absolute princes odious to the people, or to induce the Medici, by following his precepts, to render themselves insupportable and thus bring about their own fall and the restoration of the republic, are completely overthrown. Machiavelli saw clearly enough that the Medici were too firmly seated at Florence to be dislodged, and although he was himself partial to a rational system of civil liberty, if consistent with a strong government, he was still more attached to the national honour and independence of his country; and what he dreaded most was, that, through some rash ebullitions of party spirit, foreigners might be enabled to interfere and enslave Florence, as they had enslaved Lombardy and Naples. At the end of his 'Principe' (ch. xxv.) he displays this feeling with great energy. After examining the strong and the weak parts of the armies of other nations, Spanish, French, Swiss, and German, who had by turns invaded Italy, he says that it was still possible to form a native Italian army, on a new system of discipline and tactics, which might unite the advantages of each, and be able to resist them all; 'which would reflect a great credit upon a new prince, who would be looked upon as the liberator of Italy, especially by those provinces which have suffered most from foreign irruptions, and which would hail him with tears of joy and gratitude. What gates would be closed against him? what people of Italy would deny him obedience? Every one is sick of this barbarous domination. (Ad ognuno puzza questo barbaro dominio.) Let your illustrious house undertake this mission with the spirit and hope which ought to accompany just undertakings,' &c. This passage explains sufficiently that Machiavelli wrote his 'Principe' to please the Medici and to encourage them in their views of Italian dominion.

Machiavelli says, at the beginning of his treatise (ch. 2), that he does not intend to treat of republics, of which he had spoken in former works, nor of hereditary principalities because these are by precedent and custom firm and secure: but he intends to treat of what he styles mixed principalities, that is to say, where a new ruler or prince takes possession of a country, in which he must necessarily have many enemies. He illustrates, by examples from antient and modern history, how a new ruler can secure himself in his recently acquired possessions. In the 7th chapter he gives a sketch of the method pursued by Cesare Borgia, whose political art he extols. The 8th chapter treats of those who usurp the government of their own country, and he instances Oliverotto, the petty tyrant of Fermo, who after one year of usurped power fell by the arts of a greater and more able tyrant, Cesare Borgia. The 9th chapter treats of those new princes who, without any criminal violence, but with the consent of their countrymen, have risen to the supreme power. Chapter 10 treats of the strength of the various principalities. Chapter 11 concerns ecclesiastical states, and especially that of Rome. Chapters 12, 13, 14, treat of the military force, mercenary, auxiliary, and native, showing the danger of relying upon the first two species of troops. Chapter 15 treats of the things which bring to princes praise or blame. Chapter 16, of liberality and parsimony. Chapter 17, of cruelty and clemency, and whether it is better to be loved than feared. He says the sovereign should be feared without being hated, and with this view he ought to abstain from touching the women and the property of his subjects: and he repeats, that even in cases of punishment for treason, he ought not to resort to confiscation, 'because men sooner forget the death of their father than the loss of their patrimony.' The 18th chapter, which has been considered as the most obnoxious, is in answer to the question, 'In what manner ought a prince to keep faith?' Machiavelli begins by observing that everybody knows how laudable it is for a prince to keep his faith, and to are good liberality and bad in practice unsafe; but yet, he adds, we have seen in our own times that those princes who have cared little about faith and have known how to deceive mankind have effected great things. There are two ways of ruling, one by the laws and the other by force; the first is proper for men, the other for beasts; but as the former is not always sufficient, one must resort to the second, and adopt the ways both of the lion and of the fox. If all men were good, this lesson were not good; but as they are bad, and would not keep faith with you, you must not keep faith with them. And then he cites the example of Alexander VI., who did nothing else but deceive men, and never thought of any other means, always confirming his promises with the most solemn oaths, and always succeeding in deceiving others. In chapter 19 Machiavelli among other things praises the institutions of the kingdom of France at that time; and he approves of the parliament as a check upon the nobility. Chapter 20 speaks of fortresses, of factions, of the balance to be kept between various parties in the state. He says the best fortification for a prince is to be loved by his people. Chapter 21 is entitled, 'How is a Prince to conduct himself in order to acquire reputation?' and the author adduces the example of Ferdinand the Catholic. Chapter 22 treats of the secretaries of princes. 23, That flatterers ought to be shunned. 24, Why and how have the Italian princes lost their states? 25, That fortune has a great share in human affairs, and how we can resist its influence. 26, Exhortation to deliver Italy from the barbarians. Had Machiavelli written his book in the form of a commentary upon history, instead of adopting a didactic style, all that he says would be no more than matter of fact, for it was openly practised in his age and had been practised long before him. Moral considerations are of course totally out of the question in such a work. But even in its didactic form, most of its precepts were not new. Gilles Colonna (*Frater Ægidius Romanus*), an Austin friar, preceptor to Philippe le Bel, wrote for the instruction of his pupil a treatise 'De Regimine Principum,' afterwards printed at Venice in 1473, and translated into Spanish under the title of 'Regimiento de los Principes,' for the instruction of the Infante Don Pedro of Castile. This book was probably before the eyes of Machiavelli when he composed his 'Principe.' Several of the obnoxious principles of that treatise are also found in the 'Memoirs' of Comines, and in the 'Politics' of Aristotle.

The 'Principe' was first published, after Machiavelli's death, at Rome in 1532, with the permission of Clement VII. The 'Legazioni,' or letters of the political missions of Machiavelli, which are the key to his 'Principe,' were not made public till the middle of the last century.

In 1516 Machiavelli wrote his 'Discorsi sulla prima Deca di Tito Livio,' or commentary on the first ten books of Livy, which are still much admired. After the death of Lorenzo de' Medici, in 1519, Cardinal Giulio having become governor of Florence, both he and Leo X. seem to have recommended Machiavelli, and it was at Leo's request that he wrote a 'Discorso sopra Riformare lo stato di Firenze,' which was a plan of a new constitution for that state.

After 1521 Machiavelli was again employed on various missions. He was sent once to Venice, in 1525, and several times to his friend Guicciardini, who was governor first of Modena and then of Parma, for the pope. This was the time when Pope Clement VII. and the French were allied against Charles V., and when the Imperial army under Bourbon was threatening to cross the Apennines, no one knew whether to fall upon Tuscany or upon Rome. Machiavelli was sent to Parma to spy their motions. He returned to Florence in May, 1527, after Bourbon's army had gone to Rome. Being unwell in the stomach, he took some medicine of his own, upon which he grew worse, and died, after receiving the sacrament, on the 22nd June, at the age of fifty-eight. A letter of one of his sons describes the particulars of his death. He left five children by his wife Marietta Corsini, but little or no fortune. He was buried in the family vault in the church of Santa Croce; but it was only in 1787 that a monument was raised to his memory, through the exertions and liberality of Earl Cowper.

The other works of Machiavelli, not mentioned above, are:—1, 'Storie Fiorentine,' which he presented to Clement VII. in 1525, and which come down to the death of Lorenzo the Magnificent, in 1492. They rank among the best works on Italian history. The style of Machiavelli is remarkably nervous, concise, and comprehensive, and very different from that of his contemporary (and, it may be said, continuator) Guicciardini. Machiavelli has left fragments which bring down the history of Florence to 1499. 2, 'La Mandragora,' and 'La Clizia,' two comedies; 3, 'L'Asino d'Oro,' an imitation of the 'Golden Ass' of Apuleius; 4, 'Vita di Castruccio Castracani,' incomplete; 5, 'Sommario delle cose di Lucca,' which is a political and statistical account of that republic; 6, 'Sette Libri dell' Arte della Guerra,' which were highly esteemed by Frederick the Great of Prussia and other competent judges; 7, 'Discorso se la Lingua di Dante, Boccaccio, e Petrarca, debba chiamarsi Italiana, Toscana, o Fiorentina;' besides minor productions and a multitude of letters. The best editions of his works collectively are those of Florence, 1783, 6 vols. 4to.; 1796, 8 vols. 8vo.; and 1818, 10 vols. 8vo.

MACHICOLATION. [GOTHIC ARCHITECTURE, p. 221.] This term, which is obviously enough from the two French words *mèches* and *couler*, afterwards compounded into the barbarously Latinized one *machicolatum* or *machicolamentum*, was significantly bestowed on those openings in the parapet of a fortified building through which ignited combustibles (*mèches*), or melted lead, stones, &c., were poured and hurled down upon the besiegers. The apertures were formed in the soffit or under surface of the projecting parapet, which was supported upon corbel stones, the perforations themselves being in the soffit, between those stones. By this ingenious contrivance the besieged were enabled to harass their assailants in a most formidable manner, while they themselves were protected by the parapet and its battlements. Machicolations were, as frequently as not, confined to particular situations, such as over an entrance gateway and the towers flanking it, or other parts most likely to be assaulted. In ancient castellated structures the hanging parapet and machicolations contribute very much both to expression and architectural effect; but in modern buildings affecting the same style, although eminently characteristic of it, they are palpable incongruities in themselves, not so much because unmeaning, as because they carry along with them a false meaning.

MACHIN, JOHN, succeeded Dr. Torriano as professor of astronomy in Gresham College, 16th May, 1713. His death is announced in the 'Gentleman's Magazine,' 7th June, 1751, but the date of his birth is unknown. He is the author of a method for determining the quadrature of the circle, by means of the known development of an arc according to the ascending powers of its tangent, which he so modified as to render rapidly convergent. It was however by means of Dr. Halley's method that he computed the ratio of the circumference of the circle to its diameter as far as one hundred places of decimals. In the 'Philosophical Transactions' he wrote: 1, A paper 'On the Curve of quickest Descent,' xxx., 1718; 2, 'A Case of distempered Skin,' xxxvii., 1732; 3, 'Solution of Kepler's Problem,' xl., 1738. Besides the above, he published a pamphlet on the 'Laws of the Moon's Motion according to Gravity,' which was printed at the end of Motte's Translation of Newton's 'Principia,' 8vo., 1729.

(Hutton's *Tracts*, vol. i.; *Philosophical Trans.*, &c.)

MACHINE, an object by the intervention of which a motive power is made to act upon any body and overcome the force by which the latter resists the effort to change its state of rest or motion. A machine differs in no respect from a tool, an instrument, or an engine, and any one of these terms might be used indifferently for the same thing; the word tool is however generally applied to an object containing in its construction some mechanical power, and which, when in use, is held in the hand of the operator.

The advantage which any machine affords for overcoming resistance, consists in the reaction by which it supports a certain portion of the weight producing that resistance, so that the motive power has only to counteract the remainder. This may be immediately observed in those simple machines called the mechanical powers. For example; in the lever, the wheel and axle, and the pulley, whose properties depend on the theory of parallel forces (when, consequently, of the resistance, the moving power, and the reaction of the machine, some one is equal to the sum of the two others), any convenient portion of the resistance may be made to rest on the point of support, or the point of suspension.

Again; in the inclined plane, the wedge, and the screw, whose properties depend on the theory of forces concurring in a point, the motive power, the resistance, and the reaction of the support, are represented by the three sides of a triangle; and the ratio of the first to either of the others may be varied at pleasure by the construction of the machine.

The powers employed to give motion, through machinery, to any object, are produced by the muscular strength of men or animals; the actions of weights, springs, wind, water, steam, or fired gunpowder; and these powers may generally be considered as pressures exerted during certain portions of time. Even that power which is produced by a sudden impulse, as when a rammer descending by its weight falls on the head of a pile, is only a pressure existing during an indefinitely short interval of time. The point in any machine to which the moving power is applied is called the impelled, and that against which the resistance acts is called the working point.

In the employment of any machine a certain portion of the power is expended in overcoming the inertia and friction of the materials, and that which remains is the only efficient force by which the useful effect is to be obtained. Thus, in pushing or drawing a body up an inclined plane, the effective motive power is less than that which is actually expended by as much as is necessary to overcome the inertia of the body and its friction on the plane; and these might be avoided if it were possible or convenient to raise the body vertically to an equal height by the descent of a body of greater weight, when both are connected together by a string passing over a pulley. The loss of power from inertia is doubled when a reciprocating motion exists in the same machine; for a momentary state of rest takes place between every two contrary directions of the movement, and immediately afterwards a new inertia is to be overcome. The retarding forces above mentioned are evidently greater as the quantity of machinery in an engine is augmented; and hence every machine should be as simple as possible consistently with the requisite relation between the moving power and the opposing resistance.

In the construction of machinery it is evident that all abrupt variations of velocity should be prevented, on account of the irregularity which they induce in the action. When, for example, one wheel drives another by means of the teeth on their circumference, the pressure of the teeth takes place wholly on one side of the latter, and the movement may be steady if the teeth are well formed; but on a sudden diminution of the velocity of the driving wheel, that which is driven, continuing for a time to move with its actual velocity, tends further to retard the movement of the other, and the pressure of the teeth against each other takes place on the opposite side. Thus a shaking motion is produced which diminishes the efficacy of the machine. The disadvantage attending such variations in the movement of the machinery renders it advisable to gain the required effect by continued pressure, if possible, rather than by the employment of percussive forces.

It is also a maxim assented to by engineers that the impelled point of a machine should not be allowed to move with a greater velocity than that with which the motive power can act upon it; since in this case the excess of velocity in the machine will be employed in accelerating the motion of the power, and thus the general acceleration of the machine will suffer a corresponding diminution. The velocities of the impelled and working points should therefore be properly adjusted to the pressures, the inertia, and the friction, in order that all possible advantage may be derived from the machine.

A just estimate of the power of a machine ought to include the effects of all the momentary accelerations and retardations of motion to which it is subject, and all the losses arising from inertia and friction; but as the introduction of these circumstances would excessively complicate the investigation, it is usual to make the measure of the power depend on the condition that the impelled and working points shall be in a state of uniform motion. For then, agreeably to the property of the simple lever, the velocities of those extreme points will be inversely proportional to the forces which would be in equilibrio at the same points; and the rule propounded by Euler is, that in every machine, simple or complex, the pressure at the impelled point, multiplied by the velocity of that point, is equal to the product of the resistance at the working point by the velocity of the same point; or the momentum of resistance (commonly called the *performance* of the machine) is equal to the momentum of impulse. Whatever objection may be made to this rule with respect to the measure of the power in action, no doubt can exist that it affords a correct value of the useful effect; and the latter may therefore be measured by the weight which might be raised by the machine to a given height vertically in a given time. The fact is sufficiently evident when a mass of any material is to be conveyed from one place to another, or when a body is let fall on any object from a given height. It follows that, if an algebraical expression be obtained for the momentum of the resistance in terms involving that resistance, the motive power and the distances of their points of application from the axis of motion; on making the differential of that expression equal to zero, the ratio of the resistance to the moving power, when the useful effect of the machine is a maximum, may be found from the resulting equation.

If M represent the mass of any body moved, W its weight, which is equal to Mg, g (=32¼ feet) expressing the force of gravity; also, if H be the height to which the body may be raised in one second of time, and V the velocity which a body would acquire by falling vertically through a height equal to H, we shall have, by the theory of motions, $V^2=2gH$; whence $W.H$ (the momentum of resistance, or the useful effect of a machine) $=\frac{1}{2}MV^2$. This last expression is designated the living, or active, force of the body moved; and it expresses the force of a body in motion, in contradistinction to the simple pressure exercised by a body at rest.

It is commonly asserted that, in the employment of machinery, as much is lost in time as is gained in power, or that the momentum of resistance is proportional to the power employed; but this rule requires some modification. It can be shown to hold good in a well-constructed machine when the object moved resists by its inertia only; but if the inertia is but a small part of the resistance, the momentum of the latter, or the work done, is found to increase nearly as the square of the power employed.

The various ingenious contrivances which have been adopted in machines for regulating the velocities, and for converting one species of motion into another, are noticed in the article Wheels.

Descriptions of the several mills, engines, and machines used in manufactures and the arts will be found in Robison's 'Mechanical Philosophy,' in Gregory's 'Mechanics,' and under the word Manufactures in the 'Encyclopædia Metropolitana.'

MACKENZIE, SIR GEORGE, of Rosehaugh, son of Simon Mackenzie (brother of the earl of Seaforth) by a daughter of Dr. Bruce, principal of St. Leonard's College, St. Andrew's, was born at Dundee in 1636, and having finished his grammar education, which he did with much applause, he proceeded to Bourges, 'the Athens of Scottish lawyers,' as he calls it, to study the civil law. On his return he passed advocate, January, 1659, being then about 23 years old. The next year he published his 'Aretina, or the Serious Romance,' where, says Ruddeman, he gives 'a very bright specimen of his gay and exuberant genius.' The year following we find him in the important situation of justice-depute, an office in the nature of an English justice in eyre, or of assize; and in that character appointed to repair with his colleagues 'once a week at least to Musselburgh and Dalkeith, and to try and judge such persons as were there or thereabout accused of witchcraft.' Not many years afterwards, though at what time is not quite certain, he had the honour of knighthood. In the meantime he continued his literary labours. In 1663 his 'Religio Laici, or Short Discourse upon several Divine and Moral Subjects,' appeared; two years afterwards, his 'Moral Essay upon Solitude,' in which he exalts that state above public employment with all its advantages; and in 1667, his 'Moral Gallantry,' a treatise in which he attempts to establish the moral duties on the principles of honour. It was shortly after this time he entered parliament, representing the county of Ross, where the influence of his family was powerful and extensive; and in 1674 he was appointed king's advocate in the room of Sir John Nisbet of Dirleton. He continued in the office till the accession of King James, when it was given to Sir John Dalrymple; but in a short time he was reinstated and continued in office till the Revolution. Previous to this last event he had published several of his legal works, and had been instrumental in founding the Advocates' Library. It was in 1682 that this library was founded; and at its foundation he delivered an inaugural oration setting forth its advantages. In 1678 he published his 'Discourse on the Laws and Customs of Scotland in Matters Criminal.' In 1684 he published his 'Institutions of the Laws of Scotland,' a concise and, generally speaking, excellent compendium of the law; and in 1686 he published his 'Observations on the Scotch Acts.' He seems also to have attempted the establishment of a chair of law in the University of Edinburgh, but was unsuccessful in obtaining that object.

After the Revolution Sir George retired to Oxford, where he was admitted a student on the 2nd of June, 1690; but he did not live long afterwards to enjoy the retirement which he had early praised and had now begun to experience. He died on the 2nd of May, 1691; and after lying several days in state in the abbey of Holyrood House, Edinburgh, his body was conveyed to Greyfriars church-yard, attended by a procession consisting of the council, the nobility, the college of justice, the college of physicians, the university, the clergy, and many others.

Sir George was the correspondent of Dryden and other writers of England; and he was among the first Scotchmen who wrote the English language in a style approaching to purity. But it was as a lawyer, and still more as an officer of state, that he was principally distinguished; and in this last character he received the appellation, which will live with his name, of 'The blood-thirsty Advocate.'

MACKENZIE, SIR ALEXANDER, is said to have been a native of Inverness in Scotland, from which he emigrated to Canada when a young man, and there obtained a situation in the counting-house of Mr. Gregory, one of the partners of the North-West Fur Company. He had resided for about eight years in the service of Mr Gregory at Fort Chipewyan, at the head of the Athabasca lake, in the savage country to the west of Hudson's Bay, when the knowledge he had acquired of the country and the people, and his intelligence and enterprising character, determined his employers to send him out on an exploring expedition through the regions lying to the north-west of that station, and conjectured to be bounded by the Arctic Ocean, a part of which Hearne was supposed to have seen, and, as is now well ascertained, actually had seen on his visit to the Coppermine River in 1771. Mackenzie, attended by a German, four Canadians, and three Indians, together with two Canadian and two Indian women, left Fort Chipewyan, 3rd June, 1789. Embarking in their four canoes on the Slave River, the party reached the Slave Lake, with which it communicates by a course of 170 miles, on the 9th of the same month. Resting there six days, during which the ice somewhat gave way, they launched their canoes again on the 15th, and skirting the margin of the lake, reached the entrance of the river which flows from its western extremity, and is now called the Mackenzie river, on the 29th. Mackenzie pursued the north-westward course of this river, with a perseverance and intrepidity which no dangers or difficulties could subdue, till on the 15th of July it brought him to the object of his hopes, the great Northern Ocean, in lat. 69°. Returning by the same route, the party regained Fort Chipewyan on the 12th of September. On the 10th of October, 1792, Mackenzie set out from the same point on another adventurous journey, the object of which was to reach the Pacific; an attempt, the first made in North America, in which he was also successful. Proceeding partly by the Unjigah or Peace river, and partly by land, after encountering still greater difficulties than on his former expedition, he reached the sea on the 22nd of July, 1793, and returned in safety by nearly the same route. Of both his journeys Mackenzie has himself given a full account in his 'Voyages from Montreal, on the river St. Lawrence, through the Continent of North America, to the Frozen and Pacific Oceans, in the years 1789 and 1793,' 4to. Lond., 1801. The account is preceded by a general history of the fur trade (130 pages), and the volume is embellished with a portrait of the author, who soon after received the honour of knighthood. We have not been able to ascertain the date of Sir Alexander Mackenzie's death, but his name is inserted in 'A Biographical Dictionary of the Living Authors of Great Britain and Ireland,' 8vo., Lond. 1816.

MACKENZIE RIVER. [Hudson's Bay.]

MACKEREL. [Scomber.]

MACKEREL FISHERY. [Fisheries.]

MACKINTOSH, SIR JAMES, was born at Aldourie, on the banks of Loch Ness, within seven miles of Inverness, on the 24th of October, 1765. He was the son of Captain John Mackintosh, the representative of a family which for above two centuries had possessed a small estate called Kellachie, which Sir James inherited from him. Sir James Mackintosh received his education at the universities of Aberdeen and Edinburgh, at the latter of which places he took the degree of M.D., intending to practise medicine, with which view he repaired to London. He afterwards however changed his destination, and was called to the bar in 1795, by the Society of Lincoln's Inn. In 1804 he went to India as recorder of Bombay. He returned to England in 1812; in 1818 he was appointed to the professorship of law and general politics in the college instituted for the education of the civil servants of the East India Company at Haileybury. In 1830, when the Whigs came into office, Sir James was appointed a commissioner for the affairs of India. He died on the 30th of May, 1832.

Sir James's principal works are his 'Vindiciæ Gallicæ,' his 'History of England' (which he left unfinished at his death), and his 'Dissertation' prefixed to the 'Encyclopædia Britannica,' a new edition of which has lately appeared, with notes, &c., by Professor Whewell.

The 'Vindiciæ Gallicæ' is written in an easy flowing style, and displays a considerable surface of reading, the effect of which was the greater from its lying out of the track of English study at that time. This gave him some advantage over his opponent Burke, whose ignorance of the writings of the French *Economistes* was happily exposed. The 'Vindiciæ Gallicæ' obtained for its author great and sudden reputation.

The 'History of England' (published in Dr. Lardner's 'Cyclopædia,' in which work the 'Life of Sir Thomas More' is also from his pen) he left unfinished by his somewhat premature and unexpected death; and this may in part account for its being unequally executed. Particular passages of the story are rather carefully investigated; the survey of others is very slight and unsatisfactory. The remarks on some constitutional points are interesting. The general spirit is that of a very cautious and tolerant whiggism. Besides the history above mentioned, Sir James published a History of the Revolution in England in 1688, a fragment 'completed by the editor.'

In respect to his 'Dissertation' prefixed to the 'Encyclopædia Britannica,' and purporting to be 'A General View of the Progress of Ethical Philosophy, chiefly during the Seventeenth and Eighteenth Centuries,' it will be necessary to say a few words.

To write a good outline of the progress of ethical philosophy, from Socrates to Brown, tracing the course of error to its exposure, and of truth to its establishment, would require extensive reading, patient thinking, and rigid impartiality, and remains to be done; to compose a smooth, readable, drawing-room essay, is easier, and Sir James Mackintosh has done it. The retrospect of antient ethics (s. 2) is fairly written, and may have been the result of a careful perusal of Enfield, with occasional references to Cudworth. The retrospect of scholastic ethics (s. 4) bears a like relation to Bayle. The sections on 'Modern Ethics,' the 'Controversies on the Moral Faculties' (5), and the 'Foundations of a more just Theory of Ethics,' contain a review of the principal authors, and some ingenious efforts to establish Dugald Stewart's opinions on the moral sense. There is little to show that Sir James had studied any of the authors whom he criticises, except Stewart; and from the hasty and rather flippant way in which he speaks of some, particularly Mandeville and Mill, it would be less injurious to his memory to suppose that he adopted the opinions of others, than that he expressed his own after actual reading.

The language of the 'Dissertation' is fluent, but not clear and precise, and thought seems to be often sacrificed to expression, or perhaps expression studied as a substitute for thought. As a guide to the student of morals and metaphysics, it is of little value; on the contrary, from the want of clearness and precision in the language, and the habit of mistaking words for thoughts, and paying in the former coin instead of the latter, we should consider it as rather a pernicious book to place in the hands of the young. There is little danger of the more mature (at least of those whose taste has been formed on a severe and masculine standard) reading or being influenced by such works as this.

Besides the above-mentioned works, Sir James Mackintosh contributed largely to the 'Edinburgh Review.'

(*Memoir of the Life of the Right Honourable Sir James Mackintosh*, edited by his son Robert James Mackintosh, Esq., Fellow of New Coll., Oxf., 2 vols. 8vo.,London, 1835.)

MACKLIN, CHARLES, an actor and dramatic writer. His family name was Maclaughlin. The exact place and date of his birth are unknown; but according to the account of a female relative, 'he was two months old at the battle of the Boyne' (July 1, 1690), a few days previous to which event his mother travelled with him from Drogheda to a little village six miles off, in which they resided for some years. At the age of fourteen he was apprenticed to a saddler, but soon ran away and came over to England, where he contracted a marriage with the widow of a publican in the Borough. The circumstance coming to the ears of some friends, the marriage was dissolved on the grounds of *nonage*, and he was sent back to Ireland, when he became a badgeman in Trinity College, Dublin. At the age of twenty-one he again visited England, joined a strolling company, and played Harlequin, returned to Trinity College, and again to England in 1716, when he recommenced actor at Bristol. In 1725 he was a member of Mr. Rich's company at the Lincoln's Inn Fields theatre, London. On the 10th May, 1735, he unfortunately killed a brother performer, named Hallam, by accident in a quarrel, for which he was tried and found guilty of manslaughter. On the 14th February, 1741, Macklin established his fame as an actor in the character of Shylock. In 1753 he took leave of the stage, and on the 11th March, 1754, opened a tavern and public ordinary in the Piazza, Covent Garden, adding to it 'a school of oratory and criticism,' in which he gave lectures, full dressed, only to be laughed at by Foote and other wags of the day. This scheme failing, Macklin became a bankrupt, and in 1757 went to Dublin, where he assisted in laying the first stone of the Crow-Street theatre. In 1759 he accepted an engagement at Drury-Lane, and from thence went to Covent-Garden. On the 18th November, 1773, he was driven from the stage by a cabal, but brought an action, and obtained damages against the ringleaders. On the 28th November, 1788, while representing the character of Sir Pertinax MacSycophant, in his own comedy, 'The Man of the World,' his memory suddenly and entirely failed him. He made a last attempt for his own benefit, May 7, 1789, in the character of Shylock, but was unable to complete the part.

Macklin died July 11, 1797, at the great age (it is supposed) of 107, and was buried in the chancel of St. Paul's, Covent Garden.

There are ten dramatic pieces ascribed to him, but two only have kept possession of the stage, 'Love à la Mode,' a farce, and 'The Man of the World,' a comedy. His memoirs, written by J. T. Kirkman, Esq., were published in two vols. 8vo., London, 1799.

MACKNIGHT, JAMES, D.D., born 1721, died 1800, a divine of the Church of Scotland, of distinguished eminence among the theological writers of the last century. He was born in Argyleshire, studied in the university of Glasgow, but, like many of the Presbyterian divines both of his own country and of England, went abroad and finished his studies at Leyden. On his return he became a minister in the Scotch Church, and was appointed, in 1753, pastor of Maybole. In this situation he spent sixteen years, during which time he prepared two works; one, 'A Harmony of the Gospels,' with copious illustrations, being in fact a life of our Saviour, embracing everything which the evangelists have related concerning him; the other, 'A new Translation of the Epistles.' Both these works were favourably received, and are by many persons highly esteemed. The 'Harmony' has been repeatedly printed, and to the later editions there are added certain dissertations on curious points in the history or antiquities of the Jews. The theology of them is what is called moderately orthodox. While at Maybole he published also another theological work, which is held in great esteem, in defence of 'The Truth of the Gospel History.' For these his valuable services to sacred literature, Dr. Macknight received such rewards as a Presbyterian church has it in its power to give. The degree of D.D. was conferred upon him by the university of Edinburgh. In 1769 he was removed from Maybole to the more desirable parish of Jedburgh, and in 1772 he became one of the ministers of the city of Edinburgh. Here he continued for the remainder of his life, useful in the ministry, though not accounted one of the most attractive and engaging of the preachers in that city. His attention to his theological studies was unabated, and in 1795, at the age of 74, he produced his 'Literal Translation of all the Apostolic Epistles,' with a large apparatus of Commentary and Notes, and a Life of the Apostle Paul.

There is an account of the life of Dr. Macknight by his son.

MACLAURIN, COLIN, one of the most eminent of Scottish mathematicians, was descended of an antient family in Argyleshire, and was born at Kilmoddan, in that county, in February, 1698. His father was a minister of the kirk, and died shortly after the birth of his third son Colin: his mother also died when he was very young, and the care of his education devolved upon an uncle, who sent him to the university of Glasgow at the age of eleven. It is said that in the following year, meeting accidentally with a copy of Euclid, he made himself master of the first six books in a few days, a story utterly incredible upon the mere statement. It is said also, and with much more likelihood, that at the age of sixteen he had invented many of the propositions afterwards published in his 'Geometria Organica.' However this may be, he took the degree of Master of Arts with distinction in the fifteenth year of his age (1713), and afterwards lived in studious retirement till the autumn of 1717, when, after a severe competition and ten days' examination, he obtained the professorship of mathematics at the Marischal college, Aberdeen. In 1719 and in 1721 he visited London, and formed the acquaintance of many eminent men, particularly of Newton. In 1722 he travelled on the Continent as tutor to a son of Lord Polwarth; but the death of his pupil during their tour occasioned his return to Aberdeen.

In 1725 he was appointed to assist James Gregory, whose strength was declining, in the duties of his chair at Edinburgh. The want of funds to pay an assistant placed difficulties in the way of this arrangement, which were removed, but how is not clearly stated. We mention them here to record, in honour of Maclaurin, that Newton, on hearing of the obstacles, offered to pay twenty pounds a year, till Gregory's death, towards the assistant's salary, if Maclaurin were to be appointed. At Edinburgh he remained almost all the remainder of his life. When the Rebellion broke out in 1745, he exerted himself vigorously for the existing government, and the hasty works which were thrown up for the defence of Edinburgh were planned and superintended by him: fatigue and exposure laid the foundation of a mortal disorder. When the pretender entered Edinburgh, Maclaurin withdrew, to avoid making the submission which was demanded of all who had volunteered to defend the town: but he had previously managed to introduce a good telescope into the castle, and to contrive a method of supplying the garrison with provisions. He accepted the invitation of Dr. Herring, archbishop of York, with whom he remained till it was safe to return to Edinburgh. Shortly after his return he died of dropsy, June 14, 1746, aged 48 years and four months. The preceding particulars come originally from a eulogy spoken before the university by his friend and colleague Dr. Monro, the substance of which was affixed, in a biographical form, to the posthumous work on Newton's discoveries, by the editor, Patrick Murdoch. This has been copied into the 'Biographia Britannica,' Martin's 'Biographia Philosophica,' &c.: being the only authentic account of which we know.

Maclaurin married in 1733, and his wife, with two sons and three daughters, survived him. Of his character it can only be stated, from the general eulogy, that it was such as secured him the highest regard of his contemporaries.

The writings of Maclaurin are not numerous, but they have exercised considerable influence upon the mathematical studies of this country; more however we think in what has been taken from them, or on their model, by others, than in the extensiveness of their own circulation. There is both originality and depth in all of them, and we shall proceed to notice them separately.

1. The various papers which he published in the 'Philosophical Transactions' are on subjects intimately connected with his separate works. The numbers of the 'Transactions' in which they occur are 356, 359, 364, 377, 394, 408, 439, 461, 467, 469, 471.

2. 'Geometria Organica, sive descriptio linearum curva-

rum universalis,' Londini, 1720. This is an elaborate treatise on the description of curves by the intersections of moving straight lines.

2. In 1724 he gained the prize of the Academy of Sciences for an essay, proposed by that body, on the Leibnitzian method of measuring the force of bodies in motion. In 1740 he divided with Daniel Bernoulli, Euler, and Cavallieri, the prize of the same academy for an essay on the tides. This work is printed in what is called the Jesuits' edition of Newton.

3. 'A Treatise of Fluxions,' Edinburgh, 1742 (2 vols. 4to.; a second edition about 1801, 8vo.). The immediate cause of this work was the attack of Berkeley upon the first principles of Fluxions, in his 'Analyst:' it is of great prolixity, as might be expected in an elementary treatise which is written entirely on the defensive; but it must always be remarkable as having been the first work in which the principles of fluxions were placed in logical connexion with each other. The details are very extensive, forming a great body of applications, several of them quite new at the time. Among others is the theorem now known by the name of Maclaurin, but which had been previously noticed by Stirling. [TAYLOR'S THEOREM.] Of all the treatises which have been organized upon the fluxional principle, this is undoubtedly the most sound as well as complete.

4. 'A Treatise on Algebra,' 1748 (sixth edition, 1796). This work certainly surpassed all its predecessors in clearness, though far from being so logical a work as the 'Fluxions.' It contains two appendices on the general properties of curves. It was left not quite complete, and was finished by an editor.

5. 'An Account of Sir Isaac Newton's Philosophical Discoveries,' London, 1748. This work also was published from the author's papers; the editor was Patrick Murdoch. After the death of Newton, his nephew Mr. Conduitt proposed to publish his Life, and applied to Maclaurin for assistance. The latter immediately prepared an account of the philosophical systems which preceded that of Newton. But Mr. Conduitt's death frustrated the plan, and Maclaurin extending his design to the length of explaining all Newton's mechanical and cosmical discoveries, left this work in the state in which it was printed. The optical discoveries were omitted, and the editor states that the author's intention seems to have been the explanation of those parts only of Newton's discoveries which had been and were controverted. In the present day, when popular explanation of scientific points has been well studied, it would be easy to name works which are preferable to that of Maclaurin in matter and form; but in style it would be difficult to do the same. At a time when the theory of gravitation was hardly admitted by many at home, not yet received by any of note abroad, and really understood by very few, such a work was of peculiar value.

Besides the preceding, Maclaurin edited in 1745 an edition of David Gregory's 'Practical Geometry.' He was also actively engaged in many matters closely connected with scientific publication. We need do no more than mention his exertions to found an observatory at Edinburgh, which did not succeed, and a medical society: to the latter he contributed several papers. He was engaged at one time in promoting the survey of part of the north of Scotland; at another in examining and reporting on the manner of gauging vessels; and he organized and computed tables for a provident society for the widows and orphans of the Scottish clergy, in a manner which secured the stability and usefulness of the scheme.

MACLAURIN'S THEOREM. [TAYLOR'S THEOREM.]

MACLE (*Chiastolite*) occurs crystallized. Primary form a right rhombic prism. Cleavage parallel to the lateral faces of the primary form. The crystals appear to be composed of two substances: one of a yellowish white, sometimes translucent and of a glassy fracture; the other bluish black, opaque and dull. Fracture scaly, slightly conchoidal. Hardness 5·0 to 5·5. Streak white. Lustre vitreous, or vitreo-resinous. Specific gravity 2·944.

The white portion is infusible by the blow-pipe, but becomes whiter; with borax it fuses difficultly into a transparent glass. The black portion fuses into a black glass. Nitric acid dissolves it entirely.

It occurs imbedded in clay-slate on Skiddaw in Cumberland, in Wicklow, in the Pyrenees, and in many other places.

It yields, by the analysis of Landgrebe,—

Silica	68·49
Alumina . . .	30·17
Magnesia . . .	4·12
Oxide of iron . .	2·70
Water	·27
	105·75

MACLUREITE (*Condrodite*, *Brucite*) occurs imbedded in rounded masses, the larger of which present occasional crystalline appearances of rhombic prisms with dihedral terminations. Cleavage parallel to the lateral planes. Fracture uneven. Hardness 6·5. Specific gravity 3·12 to 3·25. Colour yellowish or brown. Lustre vitreous. Becomes negatively electrical by friction. Transparent, translucent.

Infusible by the blow-pipe, but becomes colourless. With borax fuses into a transparent glass, coloured by oxide of iron. Not affected by acids.

It occurs in New York and New Jersey, and also at Pargas.

Analyses—No. 1, by D'Ohsson, from Pargas; No. 2, from New Jersey, by Seybert:—

MACO'MA, Leach's name for the Venus tenuis of De Blainville, and similar species. [VENERIDÆ.]

MÂCON, a town in France, capital of the department of Saône et Loire, situated on the right or west bank of the Saône, in 46° 18′ N. lat. and 4° 50′ E. long.; 205 miles from Paris in a direct line south-east, or 244 miles by the road to Lyon through Sens, Auxerre, Autun, and Châlons sur Saône.

Mâcon was one of the towns of the Ædui, and is mentioned by Cæsar (*De Bell. Gall.*, lib. vii., c. 90) under the name of Matisco, from the oblique cases of which the present name, which was formerly written Mascon, is derived. It is mentioned in the 'Itinerary' of Antoninus, and in the 'Notitia Imperii,' in which latter it is designated Castrum, a fortress, and is noticed for the manufacture of arrows. It suffered much from the barbarians who overran the Roman empire, especially from Attila. It passed into the hands of the Burgundians and the Franks; was included in the kingdom of Bourgogne under Boson, and in the duchy of Bourgogne under the later dukes. It was much injured in the religious wars of the sixteenth century. Before the Revolution it was a bishop's see.

The town is on the declivity of a hill sloping down to the Saône, along the bank of which is a noble quay, from which the distant Alps may be seen. A green island occupies the centre of the stream opposite to the quay: and an ancient, perhaps Roman bridge, of thirteen arches, more remarkable for solidity than beauty, connects the town with the village of St. Laurent on the other side of the river, in the department of Ain, which is commonly regarded as a suburb of Mâcon. The streets of Mâcon are crooked, narrow, and ill paved: the houses are usually of stone, and substantially built. Considerable improvements have been made of late years. The ramparts of the town have been demolished and their site laid out in promenades. The former cathedral was ruined in the troubles of the Revolution, but the episcopal residence escaped, and is used for the prefect's office. The chief public buildings are the town-hall, the ancient palace of Montrevel, the theatre, and the baths, all on the quay; the general hospital, on the parade; the new church of St. Vincent, and the new prison. Among the Roman antiquities are a triumphal arch and the ruins of a temple of Janus. The population in 1831 was 10,998; in 1836 it was 11,944. The inhabitants carry on a considerable trade in the wines of the district, some of which are excellent. There are some manufactures of hosiery, linens, linsey-woolsey, earthenware, clocks and watches, and especially confectionary. There are several tan-yards and cooperages. There is a well frequented weekly market in the town, and a large corn-market is held in the village of St. Laurent. There are several yearly fairs.

Mâcon has a high school, a school of mutual instruction, and a drawing-school. There is a society of agriculture, science, and art, which possesses a good library. There are three hospitals or poor-houses, and a society for relieving the poor at their own homes. There are a primary court of justice, a tribunal de commerce, and several government offices.

The arrondissement of Mâcon has an area of 474 square miles, and comprehends 133 communes, and 9 cantons, or districts, each under a justice of the peace. The population in 1831 was 114,061; in 1836 it was 115,777. The environs of the town are delightful and productive.

Mâcon had in the middle ages counts of its own. Their county constituted the district of the Mâconnois, which nearly coincided with the present arrondissement. This district had its own states or assembly for assessing the taxes. Louis IX., otherwise Saint Louis, purchased the county of Mâcon and united it to the domains of the crown. It formed part of the duchy of Bourgogne, either at its reformation in the reign of Jean II., or by subsequent cession of Charles VII. to the duke Philippe le Bon. [BOURGOGNE.] Louis XI. reunited it to the crown of France.

MACPHERSON, JAMES, was born in 1738, at the village of Ruthven in Inverness-shire, and was sent in 1752 to King's College, Aberdeen, with a view to be educated for the Scotch church. On leaving college he was appointed schoolmaster of his native village; and it was while holding this situation that he gave to the world what appears to have been his first publication, a poem entitled 'The Highlander,' in 1758. Before this date however he had written some other poetical pieces, among which are mentioned one called 'Death,' and another called the 'Hunter,' which last is said to have been only a rude sketch of the 'Highlander.' Soon after he sent to the 'Scots Magazine' several contributions in verse, which have been preserved from oblivion by the great controversy that afterwards arose about his capacity for manufacturing the poems ascribed to Ossian, which he professed to have only translated. Some attention appears to have been first given to the traditional poetry preserved in their native dialect among the Scotch Highlanders, by Dr. Adam Ferguson, the well known historian, himself a mountaineer; by him an interest in the subject was communicated to his friends the Rev. Dr. Carlyle, minister of Inveresk, a gentleman of extensive connexions among the literary men of his day, and John Home, the author of 'Douglas.' The two latter met with Macpherson in the autumn of 1759, when he showed them some fragments of Gaelic verse, of which they prevailed upon him to furnish them with translations. These were shown to Dr. Blair, and the poets Shenstone and Gray, by all of whom they were greatly admired; and in 1760 they were published under the title of 'Fragments of Antient Poetry, collected in the Highlands of Scotland, and translated from the Gaelic or Erse Language,' with an anonymous preface by Blair. A reprint of this publication is given in the 2nd volume of Dodsley's 'Fugitive Pieces,' Lond., 1761, pp. 117-163. The fragments are sixteen in number. The effect was to induce the faculty of advocates in Edinburgh to raise a subscription for enabling Macpherson to make a tour through the Highlands with the object of collecting more poetical treasure of the same kind. What he found, or pretended to have found, he brought to London, and published there in two successive volumes, the first of which appeared in 1762, under the patronage of Lord Bute, with the title of 'Fingal, an Epic Poem in six books, with other lesser Poems;' the second in 1763, with the title of 'Temora, an Epic Poem in eight books, with other Poems.' From the first, the genuineness of these Gaelic epics was questioned by many persons; but it was more zealously asserted by more, and to Macpherson himself the notoriety which he acquired was the beginning of a long course of good fortune. In 1764 he obtained the situation of private secretary to Captain Johnstone, on the appointment of the latter as governor of Pensacola; and he was also made surveyor-general of the Floridas, in which capacity he went out to America and the West Indies, and returned to England in 1766, retaining his salary of 200*l.* a year for life. Some of the years that followed he spent chiefly in literary labour, much of it, from the popularity of his name, highly profitable. In 1771 he published, in one vol. 4to., a disquisition on the antiquities of the Scottish Celtic race, under the title of 'An Introduction to the History of Great Britain and Ireland;' in 1773 a prose translation of the 'Iliad' of Homer; in 1775 a 'History of Great Britain from the Restoration to the accession of the House of Hanover,' in 2 vols. 4to., together with 2 vols. of 'Original Papers,' which last work he sold to the booksellers for 3,000*l.* During this period of his life he also wrote several pamphlets for the ministry, in support of the war against the American Colonies, which are now all nearly forgotten. At last his appointment to the lucrative office of agent to the nabob of Arcot turned his versatile mind and pen to Indian affairs, upon which he also produced a succession of publications of temporary interest. This post brought him into parliament in 1780, as member for Camelford, for which he sat till 1790. He then retired to a considerable property which he had purchased in his native county of Inverness, where he died 17th February, 1796. His body was brought back to England for interment in Westminster Abbey. (*Edinburgh Encyclopædia*, the editor of which, Dr. (now Sir David) Brewster, married a daughter of Mr. Macpherson.) [OSSIAN.]

MACQUARIE, river. [AUSTRALIA.]

MACRA'SPIS (*MacLeay*), a genus of Coleopterous insects of the section *Lamellicornes*, and, according to Latreille's classification, belonging to the third division of that group, the *Xylophili*. The genera *Macraspis* and *Chasmodia* constitute two closely allied groups of the family *Rutelidæ*, the species of which inhabit the warmer parts of South America, and are remarkable for the large size of their scutellum. They are of tolerably large size (averaging about three-quarters of an inch in length, or rather more), usually very smooth and glossy, and often exhibit brilliant colours, green, brown, and yellow being the most common hues observable in the various species. There are some however which are of a glossy-black colour, and others which have yellow markings on a black ground (*Macraspis quadrivittata*, Olivier). The body is of an ovate form (the head and thorax having an outline continuous with that of the abdomen, or nearly so), convex above and beneath. The sternum is produced anteriorly into a pointed process, which projects between the anterior pair of legs.

In the genus *Macraspis* the mentum is longer than broad, slightly contracted anteriorly, and without any fringe of hairs on the anterior margin; the mandibles are almost triangular, and have the apex pointed and notched; the maxillæ have several denticulations.

The genus *Chasmodia* (MacLeay) is chiefly distinguished from Macraspis by the obtusely terminated mandibles, which have no notch at the extremity; the maxillæ having a tuft of hairs and only two denticulations, and the mentum being of a somewhat ovate form, distinctly contracted towards the apex and furnished with hairs. The claws of the tarsi are simple, whereas in Macraspis one of the claws of each tarsus, at least of the four anterior legs, is bifid.

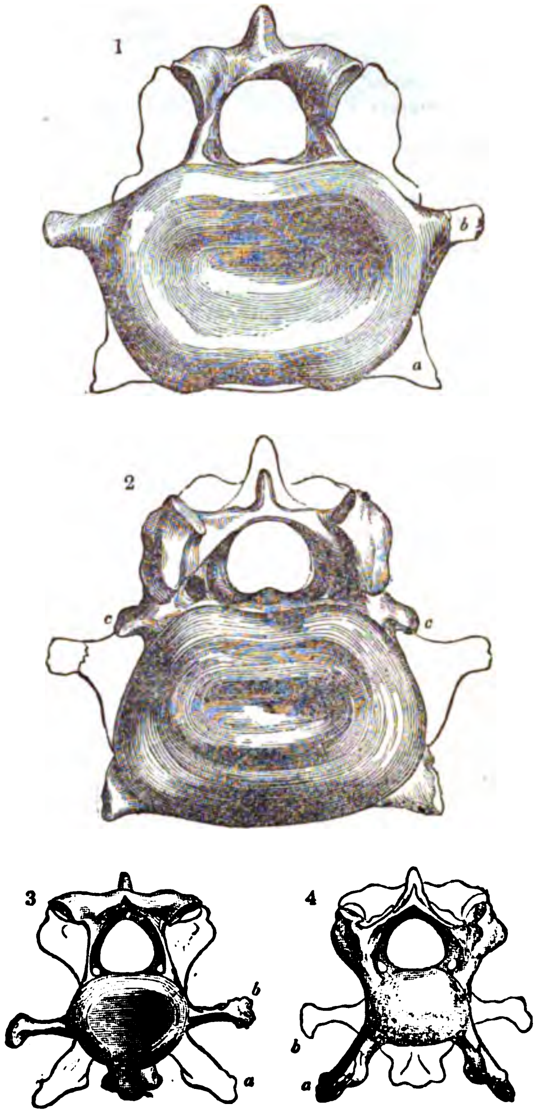
The insects of these two genera fly by day about trees, emitting a humming noise, and feed upon flowers. Collections formed in Brazil usually contain many of these insects.

Dejean, in his 'Catalogue des Coléoptères,' enumerates twenty-six species of *Macraspis* and five of *Chasmodia*.

MACRAUCHE'NIA, Professor Owen's name for a large extinct Mammiferous animal, referrible to the order *Pachydermata;* but with affinities to the *Ruminantia* and especially to the *Camelidæ*.

The remains on which the professor founded this genus included two cervical vertebræ, seven lumbar vertebræ, all more or less fractured; a portion of the sacrum and ossa innominata; fragments of the left scapula; of the right radius and ulna, and right fore-foot; the right femur nearly entire, the proximal and distal extremities of the right tibia and fibula; and a metatarsal bone of the right hind-foot. These portions of the skeleton were discovered by Mr. Darwin in an irregular bed of sandy soil, overlying a horizontal accumulation of gravel on the south side of Port St. Julian, on the east coast of Patagonia, and belonged to the same individual.

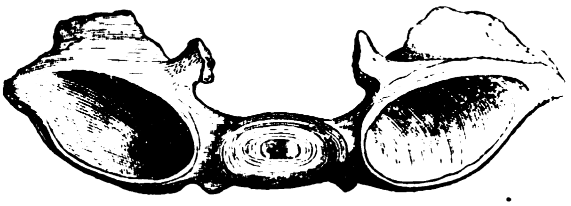
Mr. Owen observes that what is described as a perforation of a single transverse process in a cervical vertebra is essentially a space intervening between two transverse processes, a rudimental rib, and the body of the vertebræ, and the professor alludes to the manifestation of this structure in the cold-blooded saurians and in the *Ornithorhynchus*. He observes that the *Camelidæ* differ not only from the other ruminants, but from all other existing *Mammalia*, in the absence of perforations for the vertebral arteries in the transverse processes of the cervical vertebræ, the atlas excepted; and though it is true that in other *Mammalia* the two transverse processes are manifested on each side with their extremities united by a distinct cartilage, this appears in the fœtal state only, for the cartilage afterwards becomes ossified and anchylosed to them. After referring to the structures of the inferior transverse process or its representatives in the *Hippopotamus*, the *Marsupials*, and the *Giraffe*, Mr. Owen proceeds thus: 'In the long cervical vertebræ of the *Camel* and *Llama*, the upper and lower transverse processes are not developed in the same perpendicular plane on the side of the vertebræ, but at some distance from each other; the lower transverse processes (*fig.* 1, *a*) being given off from the lower part of the anterior extremity of the body of the vertebra; the upper ones (*fig.* 1, *b*) from the base of the superior arch near the posterior parts of the body of the vertebræ. The extremities of these transverse processes do not become united together, but they either pass into each other at their base, or continue throughout life separated by an oblique groove. This groove would not however afford sufficient defence for the important arteries supplying those parts of the brain which are most essential to life; and accordingly the vertebral arteries here deviate from their usual course, in order that adequate protection may be afforded to them in their course along the neck. From the sixth to the second cervical vertebra inclusive in the *Aucheniæ*, and from the fifth to the second inclusive in the *Cameli*, the vertebral arteries enter the vertebral canal itself, along with the spinal chord, at the posterior aperture in each vertebra, run forwards on the outside of the dura mater of the chord, between it and the vertebral arch, and when they have thus traversed about two-thirds of the spinal canal, they perforate respectively the superior vertebral laminæ, and emerge directly beneath the anterior oblique or articulating processes, whence they are continued along with the spinal chord into the vertebral canal of the succeeding vertebra, and perforate the sides of the anterior parts of the superior arch in like manner; and so on through all the cervical vertebræ until they reach the atlas, in which their disposition, and consequently the structure of the arterial canals, resemble those in other Ruminants. The two cervical vertebræ of the *Macrauchenia* present precisely the structure and disposition of the bony canals for the vertebral arteries which are peculiarly characteristic of the *Camelidæ* among existing *Mammalia*.' *Fig.* 2 shows the groove and orifices of the canal for the vertebral artery in a section exposing the spinal canal. Mr. Owen then goes on to show that the vertebræ of the Macrauchenia also closely resemble the middle cervical vertebræ of the Vicuña and Llama in their elongated form; approaching the Auchenial division of the *Camelidæ*, and deviating from the true camels in the relations of the length of the body of the vertebra to its breadth and depth, and in the much smaller size of the inferior processes. The author observes that, excepting the Giraffe, there is no existing Mammal which possesses cervical vertebræ so long as the Macrauchene; but that the cervical vertebræ of the Giraffe differ in the situation of the perforations for the vertebral arteries, and in the form of the terminal articular surfaces. Both the cervical vertebræ described by Mr. Owen are of the same size, and each measures 6½ inches in extreme length, 2 inches 10 lines in breadth, and 2 inches 4 lines in depth. Among the peculiarities of structure, a small longitudinal process (*fig.* 2, *c*) is given off immediately below the base of the anterior process, and this is not observable in any of the cervical vertebræ of the Giraffe or *Camelidæ*. In the form of the articulating surfaces of the bodies of the vertebræ, the Macrauchene deviates from the Giraffe and Camel, but resembles the *Aucheniæ*. The anterior articulating surface is convex and almost hemispheric in the Giraffe and Camel, whilst the posterior surface is proportionally concave, so that the vertebræ of the neck are articulated by ball and socket joints, yet not, as in most reptiles, with intervening synovial cavities, but by means of the concentric ligamentous intervertebral substance characteristic of the Mammals. The degree of convexity and concavity in the articular surface of the bodies of these vertebræ in the Llama and Vicuña is much less than in the Camels, and the former consequently carry their necks more stiffly and in a straight line. The anterior articulating surface in Macrauchenia is less convex than it is in the Llama, and the posterior surface is less concave. From an analysis of the comparative structure of these vertebræ in the Camels, the Llamas, and the Macrauchene, Mr. Owen infers that the latter carried its neck in the same stiff and upright position as is manifested in the Llamas.



Cervical Vertebræ (1, 2) of Macrauchenia, and (3, 4) of Auchenia, half nat. size.

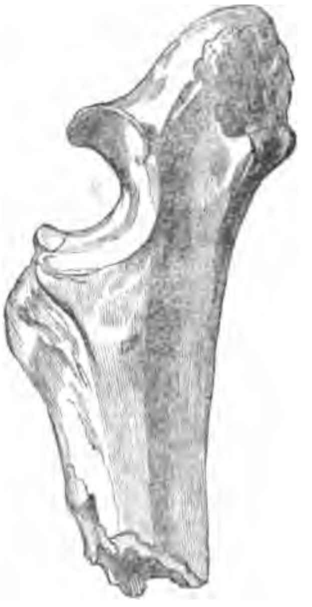
There is not in the collection a fragment of dorsal vertebræ, ribs, or sternum; but the seven lumbar vertebræ form a consecutive series from the same individual as that to which the cervical vertebræ belonged; and though these lumbar vertebræ do not possess such distinctive characters as those of the neck, they contribute not unimportantly to the illustration of the osteology of the animal and its affinities. No existing Pachyderm has more than six lumbar vertebræ; the Camels and Llamas only, among the Ruminants, possess seven; and here Mr. Owen discovered modifications of form in which the Macrauchene deviates from the *Camelidæ* and approaches the *Horse* and *Hippopotamus*. In the Macrauchenia, as in the Rhinoceros, Tapir, Hippopotamus, and Horse, the transverse processes of the last lumbar vertebræ are of considerable thickness and extent, and are joined by enarthrosis to the transverse processes of the sacrum; but the bony structure of these joints would indicate that they were not subject to be obliterated by anchylosis.

Sufficient of the sacrum and ossa innominata remain to enable Mr. Owen to state that the sacrum was anchylosed to the ilia: the lower boundary of this anchylosis is marked below by an external ridge, and by vascular canals and grooves in the substance of the bone, as in the Hippopotamus.



Last lumbar vertebra of Macrauchenia, one-third nat. size.

Of the remaining portions, the anchylosed fore-arm and leg, and the fore-foot, are the most characteristic. The portion of the antebrachium which is preserved presents a condition of the radius and ulna intermediate to those which respectively characterize the same bones in the Pachyderms and Camels. In the former, the radius and ulna are separate bones, united in the same position by a ligament, but so organized that the movement of supination cannot be effected. A bony confluence joins these bones partially in the ordinary Ruminants, but this rarely extends to the proximal extremities. In the Camel and the Llama the anchylosis is complete, so that no trace of the original separation of the radius and ulna is perceptible, and the olecranon, or elbow, appears as a mere process of the radius. The anchylosis in Macrauchenia is also complete, but the boundary-line is clearly defined, and the proportion which each of the bones contributes to the great articulating surface for the distal end of the humerus is easily distinguishable.

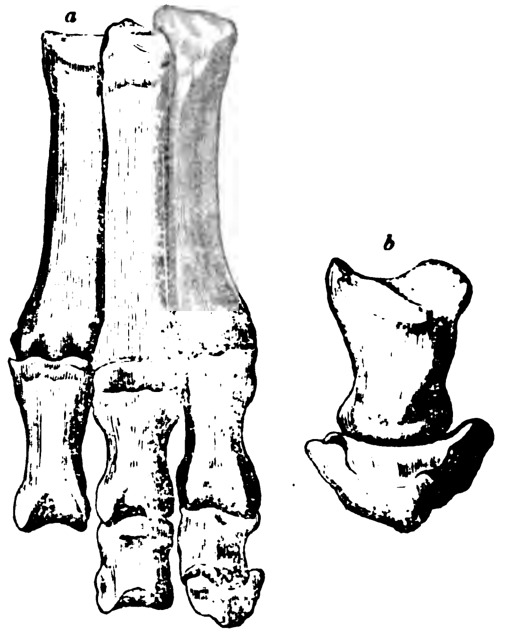


Proximal extremity of anchylosed ulna and radius of the Macrauchene, one fourth nat. size.

Mr. Owen goes on to remark that the confirmation of the close affinity of the Macrauchenia to the Pachydermatous order, which the structure of the cervical vertebræ above might have rendered very doubtful, is afforded by the bones of the right fore-foot.

These are in so perfect a condition as to make it certain that the Macrauchene had three toes on the fore-feet, and not more; and that the fully developed metacarpal bones are distinct, and correspond in number with the toes, not being anchylosed into a single cannon-bone as in the Ruminants. The bones preserved are the metacarpals, proximal phalanges, and middle phalanges of each of the three toes, and the distal or ungueal phalanx of the innermost toe.

The author observes in continuation that the bones of the leg of the Macrauchene exhibit the same transitional structure as is afforded by the definable limits of the anchylosed bones of the fore-arm. In the Pachyderms the fibula is entire and distinct. In the Ruminants (the small musk-deer excepted, and, in an inferior degree, the elk) the fibula appears only as a short continuous process sent down from the under part of the external condyle of the tibia. In the *Camelidæ* the only trace of the fibula till more rudimental state of this process, whilst in the Macrauchene the fibula is indeed entire, but it is confluent with the tibia through nearly its whole extent. The fibula and tibia are distinct bones in both the Palæothere and Anoplothere. It is to the former genus, and especially to *Palæotherium magnum*, that the Macrauchene presents the nearest approach in the general form of the tibia, the principal leg-bone; but in the Macrauchene the tibia is relatively shorter and thicker, and straighter, and less expanded at its extremities, especially the upper one, than in any of the Palæotheres.



a, Bones of the right fore-foot of the Macrauchene, one fourth natural size. *b*, second and last, or ungueal phalanx, one-half natural size.

Of the few bones of the part which are preserved the astragalus is fortunately one. Mr. Owen has compared this bone (which he justly says is the very one that an anatomist would have chosen, had his choice been limited to a single bone) with the astragalus of the Giraffe and other Ruminants, the Camel, the Anoplothere, the Hippopotamus, Rhinoceros, Tapir, and Palæothere; and he comes to the conclusion that it is with the Pachyderms having three toes to the hind-foot that the *Macrauchenia* agrees in the main distinguishing characters of this valuable bone. The results of a paper of minute detail, great research, and happy combination, are thus summed up by the professor.

'Thus we obtain evidence, from a few mutilated bones of the trunk and extremities of a single representative of its race, that there once existed in South America a Pachydermatous quadruped, not proboscidian, which equalled in stature the Rhinoceroses and Hippopotamuses of the Old World. But this, though an interesting and hitherto unsuspected fact, is far from being the sum of the information which is yielded by these fossils. We have seen that the single ungueal phalanx bespeaks a quadruped of the great series of *Ungulata*, and this indication is corroborated by the condition of the radius and ulna, which are fixed immoveably in the prone position. Now, in the ungulated series there are but two known genera—the Rhinoceros and Palæotherium—which, like the quadruped in question, have only three toes on the fore-foot. Again, in referring the Macrauchenia to the tridactyle family of Pachyderms, we find, towards the close of our analysis, and by a detailed comparison of individual bones, that the Macrauchenia has the closest affinity to the Palæotherium. But the Palæotherium, like the Rhinoceros and Tapir, has the ulna distinct from the radius, and the fibula from the tibia; so that even if the Parisian Pachyderm had actually presented the same peculiarities of the cervical vertebræ as the Patagonian one, it would have been hazardous, to say the least, while ignorant of the dentition of the latter, to refer it to the genus *Palæotherium*.

'Most interesting indeed will be the knowledge, whenever the means of obtaining it may arrive, of the structure of the skull and teeth in the Macrauchenia. Meanwhile we cannot but recognise in the coalesced and confluent state of the bones of the forearm and leg, a marked tendency in it toward the Ruminant order, and the singular modifications of the cervical vertebræ have enabled us to point out the precise family of that order with which the Macrauchenia is more immediately allied. In first demonstrating this relationship it was shown in how many particulars the *Camelidæ*, without losing the essential characters of Ruminantia, manifested a tendency to the Pachydermatous type; and the evidence which the last genera, *Macrauchenia* and *Anoplotherium*, lend to a reciprocal transition from the Pachyderms to the Ruminants through the *Camelidæ*, cannot but be viewed with extreme interest by the zoologist engaged in the study of the natural affinities of the animal kingdom.'

'The Macrauchenia is not less valuable to the zoologist in reference to the geographical distribution of animal forms. It is well known how unlooked for and unlikely was the announcement of the existence of an extinct quadruped entombed in the Paris basin, whose closest affinities were to a genus (*Tapirus*) at that time regarded as exclusively South American. Still greater surprise was excited when a species of the genus *Didelphys* was discovered to have co-existed in Europe with the *Palæotherium*. Now, on the other hand, we find in South America, besides the Tapir, which is closely allied to the Palæothere, and the Llama, to which the Anoplothere offers many traces of affinity, the remains of an extinct Pachyderm, nearly akin to the European genus *Palæotherium*; and, lastly, the Macrauchenia is itself in a remarkable degree a transitional form, and manifests characters which connect it both with the Tapir and the Llama.' (*Zoology of the Voyage of H.M.S. Beagle*, 1840.)

MACRI'NUS, OPI'LIUS, a native of Mauritania, was prefect of the prætorium under Antoninus Caracalla, whom he accompanied in his expedition against the Parthians, and caused to be murdered on the march. [CARACALLA.] Macrinus was immediately proclaimed emperor by the army, A.D. 217, and his son Diadumenianus, who was at Antioch, was proclaimed Cæsar; both elections were confirmed by the senate. Macrinus, after a battle with the Parthians near Nisibis, concluded peace with them. On his return to Antioch, he reformed many abuses introduced by Caracalla, but his excessive severity displeased the soldiers, and an insurrection, excited by Mæsa, the aunt of Caracalla, broke out against Macrinus, who, being defeated near Antioch, fled as far as Chalcedon, where he was arrested and put to death, A.D. 218, after a reign of about fourteen months. He was succeeded by Elagabalus. (Dion Cassius; Capitolinus.)

MACRO'BIUS, AMBRO'SIUS AURE'LIUS THEODO'SIUS, probably lived about the middle of the fifth century of the Christian era. We possess hardly any particulars of his life; he is generally supposed to be the person who is mentioned in the *Cod. Theod.*, vi. 8, as 'chamberlain of the royal bed-chamber' (*sacri cubiculi præfectus*), during the reigns of Honorius and Theodosius the younger, but this does not appear certain. It has also been disputed whether he was a Christian or a pagan; it has been supposed, from his occupying so high a rank at the court of a Christian emperor, that he must have belonged to the Christian religion; but this opinion seems quite at variance with the whole scope and tenor of his writings. The place of his birth is uncertain; but he informs us himself, in his preface to the 'Saturnalia,' that the Latin language was not his mother-tongue.

Three works of Macrobius have come down to us; a commentary on the 'Somnium Scipionis' in the sixth book of Cicero's 'Republic;' 'Dialogues' which were supposed to have taken place during the Saturnalia at the house of Vettius; and a 'Treatise on the Latin and Greek Verb,' which however is imperfect.

The commentary on the 'Somnium Scipionis,' which is divided into two books, is addressed to his son Eustathius. It is principally occupied with the opinions of the later Platonists respecting the laws which govern the earth and the other parts of the universe. There is a Greek version of this commentary by Maximus Planudes, in the King's library at Paris.

The 'Saturnalia' is however the most important and interesting of the works of Macrobius. Although written in very bad Latin, and full of trifling absurdities, it contains much valuable information on many subjects relating to antiquity. It is divided into seven books; the first contains a discussion on the origin of the Saturnalia and the principal Roman festivals, and on the character and history of several of the Roman deities; the second is of a more discursive nature; it unfolds at great length the whole art and mystery of joking according to the Roman notions, and relates some of the best jests of Cicero, Augustus, and other celebrated Romans, which however would scarcely excite a smile in modern society; it also gives a long account, among other things, of the luxury of the Romans, and contains a particular description of their favourite dishes. The third, fourth, fifth, and sixth books are occupied with an examination of Virgil's poems, in which a list is given of the principal passages which he imitated or copied from the Greek or preceding Latin poets; and the seventh is principally occupied with a discussion respecting the different kinds of food, and their effect on the human system.

The best editions of Macrobius are by Gronovius, Leyden, 1670; Zeunius, Leip., 1774 (which is said however, in the literary notices prefixed to the Bipont edition, to be very inaccurately printed); and the Bipont, 2 vols., 1788.

MACRODA'CTYLES, Cuvier's name for a family of Wading Birds (*Échassiers*) (GRALLATORES), which have very long *feet*, formed for running over marshy or watery plains, or even for swimming, especially in those numerous species which have the feet fringed or bordered. There is not however any membrane between the bases of their toes, not even between those of the external ones. The *bill*, which is more or less compressed on the sides, is lengthened or shortened according to the genera, without however arriving at the firmness or weakness of Cuvier's preceding family. [LONGIROSTRES.] The body of these birds is also singularly compressed, a conformation which is governed by the narrowness of the sternum; their wings are moderate or short, and their flight weak. The hind toe in all is rather long. Cuvier observes that this family has been divided into two tribes, according to the presence or absence of the spur on the wing; but he adds that this character is not without exceptions. The following genera are arranged by Cuvier under this family, which terminates his order *Échassiers*:—*Parra*, *Palamedea* (including *Chavaria*), *Megapodius*, *Rallus*, *Fulica* (including *Gallinula* and *Porphyrio*), *Chionis*, Forst. (*Vaginalis*, Lath.), *Glareola*, Gm., *Phœnicopterus*. Cuvier's sixth order, *Palmipèdes*, immediately succeeds this family, which is somewhat heterogeneous, and composed of birds whose habits are not similar. *Phœnicopterus* cannot be said to be without any membrane 'between the bases of the toes, &c.,' for its anterior toes are united to the nails by a lunated membrane. [FLAMINGO.]

MACROUDITES. [FORAMINIFERA, vol. x., p. 349.]

MA'CROPA. [MEGALOPA.]

MACROPHTHA'LMUS. [GONOPLAX.]

MACROPO'DIANS, a tribe of brachyurous decapod Crustaceans, being the first of the family of *Oxyrhynchi* (Milne Edwards), and nearly corresponding with the genus *Macropus* of Latreille, remarkable for the enormous length of their feet, which has obtained for them the name of *Sea-Spiders*.

Form of the *Carapace* various, but in general triangular, very often not extending upon the last thoracic ring. The anterior *feet* short, and nearly always very slender; those of the succeeding pairs always more or less filiform; the length of the second pair often nine or ten times the length of the post-frontal portion of the *carapace*, and always much exceeding the double of that portion; the succeeding feet in general very long also. The basilary joint of the *external antennæ* nearly always constitutes the major part of the lower wall of the orbit, and proceeds to solder itself to the front. In the greater portion of the tribe the third joint of the *external jaw-feet* is inclined to oval or triangular, longer than it is wide, and does not support the succeeding joint on its anterior and internal angle, as in the other *Oxyrhynchi*. (M. Edwards.)

Habits, Food, &c.—The localities of the Macropodians are considerable depths in the sea, where they lie hid among the sea-weeds; they are also found on oyster-banks. They walk slowly and unsteadily. The weakness of their claws must render them not formidable to other marine animals, and the probability is that they live principally on *Annelids*, *Planariæ*, and small mollusks. (M. Edwards.)

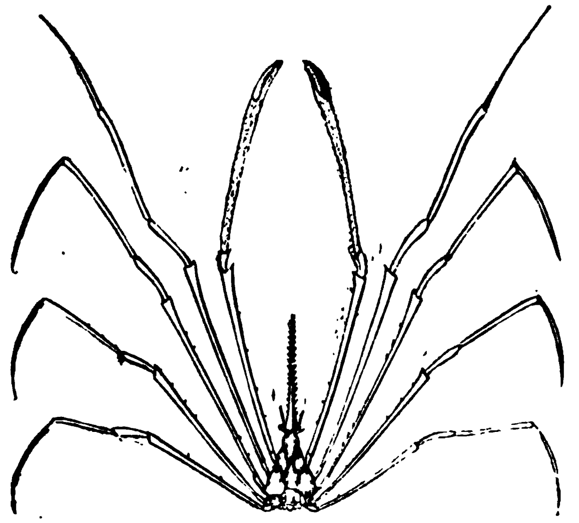
Genus, Leptopodia. (Leach.)

Established at the expense of the genera *Inachus* of Fabricius and *Macropus* of Latreille. M. Milne Edwards observes that it is very remarkable for the general form of its body and the excessive length of the feet; and states that it presents in an exaggerated manner all the distinctive characters of the family and of the tribe to which it belongs.

Generic Character.—Carapace nearly triangular, and not covering the last ring of the thorax; *rostrum* styliform and of enormous length; *eyes* large and not retractile; *internal antennæ*, when folded back, following the longitudinal direction of the body. First joint of the *external antennæ* very long and completely confounded with the neighbouring parts of the shell, the second inserted at a considerable distance in front of the orbits and below the rostrum. *Epistome* much longer than it is wide. Third joint of the *jaw-feet* nearly triangular, and carrying at its external angle the succeeding joint, which is very much developed. The *sternal plastron* as long as it is wide, but very much narrowed between the first pair of *feet*, which are very slender and extremely long, but less than any of the rest; the length of those of the second pair equals nine or ten times the length of the post-frontal portion of the carapace. *Abdomen* in both sexes composed of six joints, of which the first, which is very much developed, and as long as it is wide, occupies the dorsal surface of the body, while the last is formed by the soldering of the sixth and seventh abdominal rings. (M. Edwards.)

Geographical Distribution of the Genus. — Coasts of America and of the Antilles, as far as is at present known.

Example, *Leptopodia sagittaria*, Leach (*Cancer seticornis*, Herbst.; *Inachus sagittarius*, Fabricius).



Leptopodia sagittaria.

Latreillia. (Roux.)

Generic Character.—Carapace triangular, truncated anteriorly, and not covering the last ring of the thorax; *epistome* much longer than it is wide; second and third joints of the external *jaw-feet* very narrow; *feet* filiform and very long; *abdomen* of the female of five joints only, though the sutures of two others may be distinguished; structure of that of the male not known.

Example, *Latreillia elegans*, the only species known.

Description.—Carapace smooth, front armed above with two large divergent horns, and with a spine directed forwards between the antennæ; feet of the four last pair with the third joint spiny, the penultimate joint a little dilated above towards its extremity, and the tarsus very short; abdomen armed with six spines, two of which are situated on the median line, and four near the edges; length about an inch; colour yellowish.

Locality.—The coasts of Sicily.

M. Milne Edwards thinks that the *Maia seticornis* of Bosc should be placed near this species.

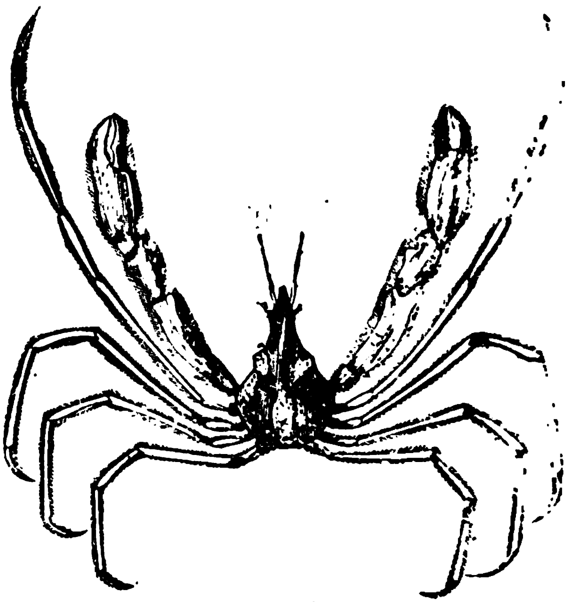
Stenorhynchus. (Lamarck; Latreille.)

Generic Character.—Carapace triangular and not prolonging itself above the last thoracic ring. *Rostrum* advanced, bifid, and sharp; *orbits* circular, eyes rather projecting and not retractile. Internal *antennæ* capable of being folded back longitudinally, and the fossets in which they are lodged not completely separated from each other. The first joint of the external antennæ confounded with the neighbouring parts and very narrow; the second inserted on the sides of the rostrum, and the third much longer than the second. *Epistome* longer than wide, and the *pterygostomian regions* rudimentary; *buccal frame* longer than it is wide: *external jaw-feet* narrow; third joint oval and the fourth rather long. *Sternal plastron* narrow between the anterior feet, but afterwards wider and presenting on the median line a suture which occupies the last segment of it. *Feet* of the first pair short, but much larger than the succeeding ones, the claw (manus) which terminates it convex, and the fingers a little curved inwards. Four last pair of feet filiform and extremely long; the length of those of the second pair equal five or six times of the width of the carapace, the others become progressively shorter; their penultimate joint is a little dilated towards the end, and the last joint is styliform and a little recurved. *Abdomen* in both sexes composed of six joints, the last of which is formed by the union (soudure) of the sixth and seventh rings. (M. Edwards.)

Geographical Distribution of the Genus.—European seas.

Example, *Stenorhynchus Phalangium* (*Cancer Phalangium*, Pennant; *Cancer rostratus*, Linn.; *Macropus Phalangium*, Latreille; *Macropodia Phalangium*, Leach).

Locality.—Coasts of the English Channel, &c.



Stenorhynchus Phalangium.

Achæus. (Leach.)

This genus is very nearly allied to *Stenorhynchus* and *Inachus*, but is distinguished from all the other genera of this family by the form of the posterior feet and some other characters.

Generic Character.—Carapace, as in the greater part of the family, not extending on the last segment of the thorax, nearly triangular, and convex on the branchial regions. *Rostrum* nearly null; eyes not retractile, and curved up on rather long peduncles; first joint of the external antennæ soldered to the front and advancing above the level of the internal canthus of the eyes; the second joint inserted on the sides of the rostrum and entirely exposed above. *Epistome* nearly square; third joint of the external jaw-feet longer than wide, nearly triangular, and giving attachment to the succeeding joint near its anterior and external angle. *Sternal plastron* suddenly narrowed between the anterior feet, which are slender and short, while those of the succeeding pairs are filiform; the second pair are nearly twice and a quarter longer than the post-frontal portion of the carapace, and terminate by a styliform and entirely straight joint; the succeeding feet are much shorter, and the terminal joint of the four last is large, compressed, and falciform. *Abdomen* composed of six joints in both sexes. (M. Edwards.)

Geographical Distribution of the Genus.—Achæus has, hitherto, been only found in the British Channel.

Example, *Achæus Cranchii*.

Description.—Rostrum formed of two small triangular teeth and not extending beyond the second joint of the external antennæ; a spine on the anterior face of the ocular peduncles; genital and cardial regions elevated in the form of tubercles; feet with very long hairs, and hooked. Length from six to eight lines. Colour brown.

Locality, Habits, &c.—Falmouth in England, and the mouth of the Rance near Saint Malo. The species lives among the sea-weeds and oysters.

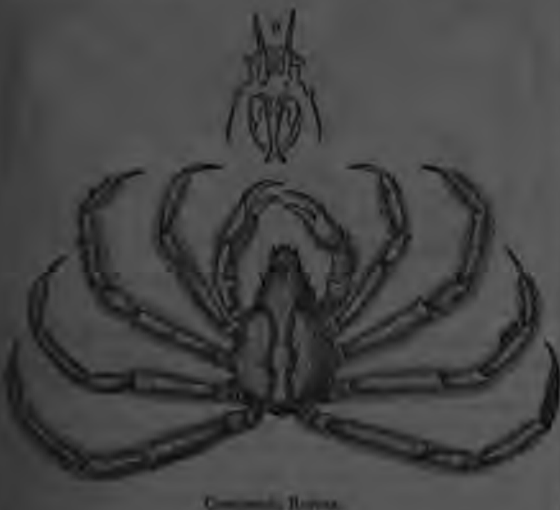
Camposcia. (Leach; Latreille.)

Generic Character.—*Carapace* convex and nearly piriform, but truncated anteriorly; *rostrum* rudimentary and scarcely reaching beyond the internal canthus of the orbits. *Eyes* supported upon peduncles, which are rather long, recurved anteriorly, and very large at their base; they are capable of being reflected backwards, but they are not retractile, for there is no post-foraminary orbital cavity for lodging them, their extremity being only protected by a spine of the lateral part of the carapace. The internal antennæ are reflected a little obliquely forwards; the fossets which lodge them have this particularity, viz. that they are not separated, as they are ordinarily, by a longitudinal partition, and form only a quadrilateral cavity. The first joint of the *external antennæ* is long and delicate, and is continued nearly as far as the rostrum, carrying at its extremity a moveable stem, which is consequently completely exposed. The *epistome* is nearly square, and the external jaw-feet are very much elongated and only close the mouth imperfectly. The *feet* are slender and very long; in the female the first pair are the shortest and are not stouter than the succeeding ones; those of the third, the fourth, and the fifth pair are a little longer, and are also terminated by a cylindrical nail slightly curved downwards. Form of the feet of the male, and disposition of the abdomen in this genus, not known. (M. Edwards.)

Geographical Distribution of the Genus.—The seas of Asia.

Example, *Camposcia retusa.*

Locality unknown.



Camposcia Retusa.
a, Inside of head.

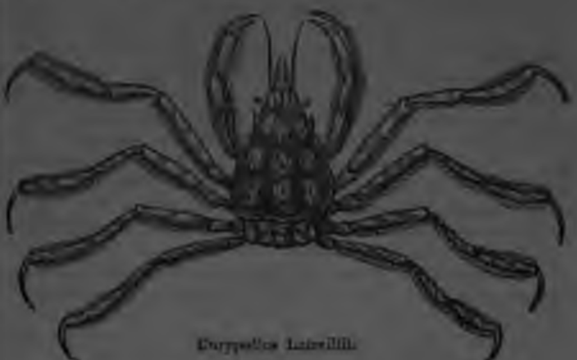
Eurypodius. (Guérin.)

A genus, forming in certain points a passage between the *Macropodians* already noticed and some of the *Maiidæ*, such as *Halimus auritus*; approaching the latter in the form of the feet, and resembling the former in the length of those members and in the disposition of the eyes.

Generic Character.—*Carapace* triangular, twice as long as it is wide, rounded posteriorly, narrow anteriorly, uneven and unequal above; *rostrum* formed by two long and horizontal horns; *eyes* carried on peduncles of moderate length and not retractile; disposition of the internal and external antennæ nearly the same as in *Stenorhynchus*, *Inachus*, &c.; epistome wider than it is long; third joint of the external jaw-feet nearly square, as wide as it is long, and deeply notched anteriorly and internally, in order to give insertion to the succeeding joint. Anterior *feet* of the length of the body in the male and much shorter in the female; they are a little convex and the fingers are slightly curved inwards. The succeeding feet are very long, their third joint is cylindrical, but the fifth is compressed and dilated below; its greatest width is below the middle; the finger is large, recurved, very sharp, and capable of being bent back against the lower edge of the preceding joint, after the manner of a subcheliform claw; the length of the second pair of feet is nearly twice and a half that of the post-frontal portion of the carapace, and the succeeding feet diminish successively in length but very little. *Abdomen* composed of seven joints in both sexes. (M. Edwards.)

Geographical Distribution.—Indian Sea.

Example, *Eurypodius Latreillii.*



Eurypodius Latreillii.

Locality.—Falkland Islands.

Amathia. (Roux.)

This genus agrees in some respects with the *Pericera* of Latreille; indeed the aspect of both is the same, but the external antennæ of *Amathia* have not the peculiar disposition which is visible in *Pericera*, and the space which the orbits leave between them is scarcely wider than the base of the *rostrum*, whilst in Pericera it is more than double.

Generic Character.—*Carapace* in the form of an elongated triangle with a rounded base; its upper surface and its borders beset with enormous spines; the *rostrum*, which is terminated by two large divergent horns, nearly as long as the post-orbitary portion of the carapace. *Eyes* small and partially protected by a spine which occupies their external canthus, but, as in the preceding genera, they are not retractile and always remain projecting. *External antennæ* presenting nothing remarkable; the basilary joint is long, very narrow, and soldered to the front; the stem is inserted under the rostrum, at some distance before the level of the eyes; it is very slender, and its two first joints are of equal length. *Epistome* large and nearly as long as it is wide; the third joint of the external jaw-feet is dilated outwards and truncated at its two internal angles. The first pair of *feet* are shorter than the succeeding ones; they are filiform in the female and a little convex or swollen in the male. The succeeding feet are long and filiform; the second pair are more than thrice as long as the post-orbitary portion of the carapace, without including the posterior spine; the others are much shorter, their terminal joint is long, sharp, and without either spines or teeth on its inferior surface. *Abdomen* composed of seven joints in both sexes. (M. Edwards.)

Example, *Amathia Rissoana.*

Description.—Carapace armed with thirteen enormous spines, three of which elevate themselves from the stomachal region, one from the cardial, and the others occupy the border of the buckler; one on the intestinal region, three on each side upon the branchial region, and one upon each of the hepatic regions: there is a small spine in front of the eyes, and a larger one at the anterior angles of the buccal frame. *Feet*, as well as the carapace, covered with a sort of down. Length about two inches; colour yellowish, with two spots, red upon the front.

Locality.—Toulon.

Inachus. (Leach.)

The genus *Inachus*, as established by Fabricius, comprehended nearly all the *Oxyrhynchi*, with the exception of the *Parthenopidæ*. The genus is now much restricted.

Generic Character.—*Carapace* nearly triangular, not much longer than it is wide, and highly embossed above.

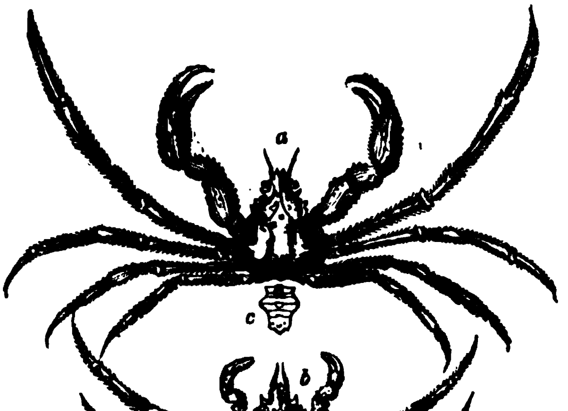
Rostrum very short; disposition of the eyes different from that in the previous genera in the system of M. Milne Edwards, the peduncles being capable of being reflected backwards, and being lodged in an orbitary cavity, which, though not deep, is very distinct. Internal *antennæ* without anything remarkable; the first joint of the external antennæ soldered to the front before the internal canthus of the eyes, and the second advanced on the sides of the rostrum. Epistome rather wider than it is long; third joint of the *jaw-feet* much longer than it is wide, nearly of the form of a triangle with its base in front, and giving attachment to its succeeding joint near its anterior and external angle. *Sternal plastron* narrowed suddenly between the feet of the first pair, and with its length not equal to its greatest breadth. *Feet* of the first pair very small in the female, but very large in the male, and sometimes thrice the length of the body; the claws always pointed and curved inwards. The succeeding feet cylindrical, slender, and more or less filiform; the second pair, always longer than the first, are thrice or four times the length of the post-frontal portion of the carapace; the others diminish successively in length, and all terminate in a very long cylindrical joint, which is pointed and but little or not at all curved. The *abdomen* is composed of only six distinct joints.

Localities and Habits of the Genus.—All the species are small, and have hitherto been found on the coasts of Europe, particularly those of England and France. In the latter country they have been taken both on the northern and Mediterranean shores. They often haunt coves where there are oysters, and all of them have the body covered with down and hairs, to which sponges and corallines attach themselves. Colour brownish. (M. Edwards.)

M. Milne Edwards divides the genus into three sections: the first containing one species, having the stomachal region furnished with five spines or tubercles, including one (median and posterior) very strong, and four small ones anteriorly on a transversal line.

Example, *Inachus Scorpio.*

Locality.—The British Channel, &c.



Inachus Scorpio.

a, male; *b*, female; *c*, abdomen of male; *d*, abdomen of mature female; *e*, abdomen of immature female.

The second section consists of *Inachi dorynchus* and *thoracicus*, and the third of *Inachus leptorhynchus.*

Egeria.

This genus is Asiatic in its geographical distribution, and M. Milne Edwards divides it into two sections; the *first* with the third joint of the external jaw-feet deeply notched at its anterior and external angle (*Egeria arachnoides* and *E. Herbstii*), and the *second* with the third joint of the external jaw-feet not notched at its anterior and internal angle (*Egeria Indica*). [EGERIA, vol. ix., p. 304.]

Doclea. (Leach.)

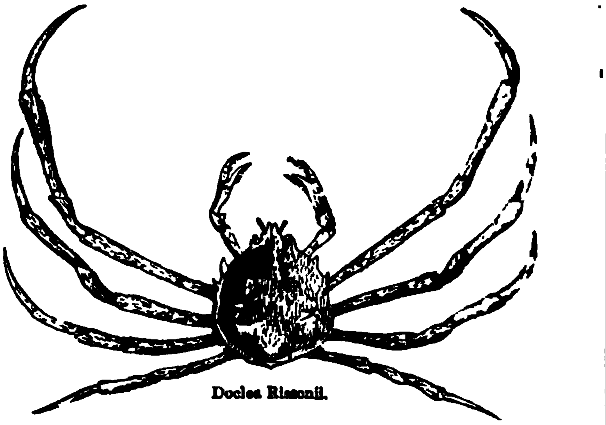
Generic Character.—*Carapace* nearly globular, hairy, and more or less beset with spines; *front* raised, and the lateral edges of the carapace, instead of joining the orbits, directed towards the anterior border of the buccal frame; *rostrum* short and very narrow; the *orbits* directed obliquely forwards, and entirely lodging the eyes, which are very small, and have no trace of a spine at the anterior angle of their upper border, a character which renders them easily distinguishable from the *Libiniæ.* The basilary joint of the external antennæ advances much beyond the internal canthus of the eyes, and terminates nearly in a point under the front, to which it is intimately united; the second joint of these antennæ is short and placed near the edge of the rostrum; the third and the fourth joints are very small. *Epistome* very little developed, and much wider than it is long. The third joint of the external jaw-feet is nearly square, slightly dilated outwards, and rather deeply notched at the internal and anterior angle. *Sternal plastron* nearly circular; the anterior *feet* weak and very small, not more than once and a half of the length of the carapace, the hand nearly cylindrical. The succeeding feet very long, though not always equalling those of the *Egeriæ*, slender, and cylindrical; their terminating joint long and styliform; the second pair from twice to thrice as long as the post-frontal portion of the carapace, and the succeeding pairs diminishing progressively. The *abdomen* varies; sometimes only five distinct joints are to be detected in that of the female; sometimes there are seven, as in the male.

M. Milne Edwards, who gives the specific character here stated, observes that the *Docleæ* bear the greatest analogy to the *Egeriæ*, and establish the passage between those *Macropodians* and the *Libiniæ* which belong to the tribe of *Maiians.* [MAIIDÆ.]

Geographical Distribution of the Genus.—Where known, the Indian Seas.

Example, *Doclea Rissonii.*

Locality unknown. (*Hist. Nat. des Crustacés.*)



Doclea Rissonii.

MA'CROPUS, the scientific name for the Kangaroo. [MARSUPIALIA.] The term is also used by M. Latreille to designate a genus of brachyurous decapod crustaceans. [MACROPODIANS.]

MACRORHAMPHUS. [SCOLOPACIDÆ.]

MACROURA, or MACRU'RA, the scientific name for that section of Crustaceans which have the abdomen, usually called the tail, long in contradistinction from that section (*Brachyura*), which have the tail short. The common lobster is an example of a Macrurous crustacean, and the common crab of a Brachyurous crustacean. [CRUSTACEA, vol. viii., p. 197.]

MADAGASCAR (called by the natives Madecasse), a large island in the Indian Sea, about 240 miles from the coast of Mozambique on the eastern shores of Africa, extends from 12° S. lat. to 25° 45′ S. lat., and between 43° and 51° E. long. From north to south, between Cape Ambré, or Natal, and Cape Mary, or Romain, it is 960 miles long with a width varying from 200 to 500 miles: it is estimated to cover a surface of 225,000 square miles, or somewhat more than the extent of France. It is separated from the continent of Africa by the Channel of Mozambique.

Though a short description of this island occurs in Marco Polo, and it was discovered by the Portuguese in 1506, we are still very imperfectly acquainted with its natural features and riches. It is stated that a mountain-range traverses the island in its whole length, and that some of the summits rise to an elevation of 10,000 or 12,000 feet. Its offsets cover the greater part of the interior, and in some places approach to the very shores of the sea, especially along the western coast between Cape Passandava and Cape Ambré, where the stupendous peak of Matowla rears its head not far from the shore, and also south of Cape St. Andrew in different places. But between Cape St. Andrew and Cape Passandava a low marshy plain extends along the shore, and runs 50 or 60 miles inland. This part of the coast is indented by bays, harbours, and rivers, admirably adapted for commerce, but they are all neglected, with the exception of Bombatooka. The eastern coast seems to be high and rocky from Cape Ambré to the large bay of Antongil, one of the most spacious harbours of the Indian Sea. South of this bay the shores are low and swampy to a distance inland varying from 10 to 30 miles, and extremely unhealthy. In the interior the country in many places contains extensive plains, which are excellent pasture-ground, and frequently possess a soil adapted to all kinds of tropical plants.

Bombatooka Bay, on the western coast, is the estuary of several rivers. It is 17 miles deep and three and a half wide at the entrance; but inside it is nearly eight miles wide. Bombatooka itself is an inconsiderable village, but Majunga, on the north side of the bay, is a large town and the harbour of Thanaan-arive, the capital of the Ovahs, the most powerful, industrious, and civilized nation of the island. Vessels drawing 12 feet water can proceed to Majunga and 15 miles up the bay. From this point to the mouth of the river Betsibooka, a distance of 10 miles, there is an extensive basin, deep enough to be navigated by vessels of considerable burden; in spring-tides the water rises 20 feet at the mouth of the river. From its mouth to Thanaan-arive is a distance of 240 miles by the road. Boats sail 120 miles up the Betsibooka; from the point where the navigation terminates merchandise is carried overland to Thanaan-arive, a distance of about 85 miles. Following the road from Majunga along the Betsibooka to the capital, the country is low and swampy for 60 miles, but well adapted to the culture of rice; 40 miles farther, the land is more elevated and the rafia tree (Sagus rafia) abounds. Then for 70 miles a barren country intervenes, and the remaining distance of 70 miles to the capital is rather a level country, in which rice, sugar-cane, and cotton are cultivated.

Thanaan-arive is situated in 18° 56′ S. lat. and about 47° E. long., at an elevation of about 4000 feet above the sea-level. In 1817 it had more than 80,000 inhabitants, but has since much increased. It contains some well-built houses, and a few in the European fashion have been erected in modern times, under the reign of Radâma. It does not seem that there is a frequent communication between this place and Tamatave, a seaport on the eastern coast (18° 10′ S. lat. and 49° 31′ E. long.), which has a good anchorage with a hard and sandy bottom. The entrance to Tamatave however is between reefs, and ships are exposed to easterly winds. It carries on some commerce, though it was destroyed by the French in 1819.

South of Tamatave is the mouth of the river Mancoroo, or Mangorow. It traverses an extensive country, which is generally level and of great fertility, and contains extensive pastures. The Mangarow seems to be the most important river which descends from the eastern declivity of the interior mountain-range.

According to all accounts the climate of Madagascar is not so hot as might be expected from its geographical position. The elevated range in the interior, and the wind constantly blowing from the sea, render the heat supportable. The interior is very healthy, but the low swampy coast, which contains numerous lakes, and in certain seasons large sheets of stagnant water, is as destructive to the health of Europeans as any place in the East or West Indies. The year is divided between the dry and the wet seasons. The first occurs when the sun is in the northern hemisphere, and then the south-east monsoons prevail. During the north-west monsoons, which blow when the sun is in the southern hemisphere, rains are abundant, and sometimes incessant for several days.

It seems that Madagascar contains a very large proportion of fertile soil, and will produce nearly every kind of grain. Rice is the principal object of agriculture; there are seven varieties indigenous in this island, and it is cultivated either on high or low ground, but with little care. Other plants which are raised are manioc, or cassava root, Indian corn, and sweet potatoes. These plants have been imported, and their culture spreads more and more over the island. Indigenous plants used as food are the prickly yam (*Dioscorea aculeata*), and another species (*Dioscorea bulbifera*), the eatable arum, or bread fruit, and many varieties of plantain; also the *Maranta Madagascariensis*, which produces arrow-root, and is very nutritious. The *Sagus rafia* is much cultivated on account of its leaves, the fibres of which are ingeniously woven into cloth which is worn by the greater part of the natives. The dresses of the higher classes are manufactured of silk or cotton. The silkworms of this island are of a large size, and suspend their cocoons from the branches of trees. They feed on the leaves of *Cytisus Cajan*, or Pigeon-pea, which is indigenous in Madagascar. Of the sugar-cane there are also several indigenous varieties. The fruits of the allspice of Madagascar (*Agathophyllum aromaticum*), of the grand cardamum (*Amomum angustifolium*), and the negro-pepper of the Indies (*Capsicum frutescens*) are used as condiments. By an incision into the bark of the *Urania speciosa*, a glutinous juice is obtained which is very nourishing; and the leaves of this tree are used in building and thatching houses. There are eleven varieties of tobacco indigenous in this island. Coffee has been introduced by the French, and succeeds very well. The cocoa-nut tree and the mangrove abound along the shores.

Only cattle, sheep, fowls, ducks, and geese are kept. Wild swine are numerous, and on the western coast it is stated that wild cattle are found, some of them without horns. The large wild animals of the African continent are not met with, but macaucos, caimans, and serpents abound.

The mineral wealth of the island is not much known. It is certain that iron-ore, potters' clay, plumbago, and tin abound; and it is stated that silver and copper also occur in the mountains.

The population is estimated to amount to between four and five millions. The inhabitants seem to belong to different races, which have mixed together, and speak only one language, which contains a great number of Malay words. The inhabitants of the shores are short, rather darker than mulattoes, with low foreheads, broad and flat faces, and large eyes and mouths. Their hair is long but crisped. The Ovahs, who inhabit the elevated plains in the interior, are in height rather above the European standard, portly in their person, and of all shades of colour from deep black to copper (the latter colour however is prevalent), and their hair is long and lank. The Madegasses have made considerable progress in the arts of civilization, which is evinced by the houses they build in a climate which does not require such substantial dwellings. In agriculture and the arts connected with it they are perhaps not inferior to the inhabitants of Java, and certainly not to those of Sumatra. The Ovahs are distinguished by their superior skill in manufacturing silk and cotton dresses, in forging iron, which they apply to various purposes, from the blade of a lance down to a needle, and in the making of silver and gold chains, balances, and other articles, in which great ingenuity is displayed. Their language is written in the Arabic character. Their religion is idolatry, not founded on any sacred writings; a circumstance which may partly explain why the exertions of the Christian missionaries who have been sent to this island in recent times have been more successful here than in most other countries. It appears that by a royal edict of 1835, the public profession of Christianity was forbidden in the island. Those who violated the edict have been punished with confiscation of their property; and the married men who professed Christianity have been sold into slavery, with their wives and children. One native woman, after being in vain menaced, with the view of inducing her to impeach her companions, endured an ignominious and cruel death (August, 1837) with all the constancy of a Christian martyr. (*Missionary Register*, Jan. 1838.)

Madagascar is said to be divided into twenty-two states, governed by kings; but in the present century most of them were subjected to the sway of the Ovahs, by King Radâma, who died in 1828. This extraordinary man, who in energy of character resembled Peter the Great, introduced into his country the arts and civilization of Europe. He established a communication with the English in the island of Mauritius. He received and protected the missionaries, and promoted the establishment of schools, the number of which at the time of his death had increased to more than 100, in which nearly 5000 children were instructed. Several young people were sent to the Mauritius and even to England to receive instruction. European mechanics were well received and employed by Radáma. He introduced into his army the discipline and arms of the English. Besides the Ovahs, the Seclavas have distinguished themselves, but only as pirates. They inhabit the north-western shores, from whence they send fleets consisting of several small vessels to the Comoro Islands and even to the coast of Mozambique for the purpose of making slaves; but since the abolition of the slave trade, which Radáma, their conqueror, effected at the request of the English, their excursions have been less numerous and destructive. Still however slavery exists in Madagascar.

The French alone have tried to establish colonies on this island. The first attempt was made in 1665, and several others were made afterwards. These settlements never prospered, partly on account of the unhealthiness of the low western coast, where they were formed, and partly on account of the warlike character of the inhabitants. Since the return of peace in Europe the French have again made some attempts in two or three places. In 1821 they settled on the Isle Madame St. Mary, which is north of the harbour of Foule Point, and is 31 miles long, and from two to three miles in breadth. This settlement is improving, though the French at first suffered much from the climate. There is another settlement at Foule Point Bay, but it is inconsiderable. There are also small settlements at S. Luce (24° 44′ S. lat.), and on the tongue of land called Tholangar (25° 10′), where the French have built a small fortress, called Fort Dauphin. In these establishments the French cultivate sugar, coffee, and other tropical productions, which are sent to the island of Bourbon. The English of the Mauritius fetch from the harbour of Tamatave, rice, cattle, tortoise-shells, amber, and some minor articles. Some parts of Madagascar keep up a commercial intercourse with the southern coasts of Arabia.

(Owen's *Voyages to explore the Shores of Africa, Arabia, and Madagascar;* Locke Lewis's 'Account of the Ovahs,' in the *London Geographical Journal*, vol. v.; and *History of Madagascar*, by the Rev. W. Ellis.)

MADDALO'NI. [LAVORO, TERRA DI.]

MADDER (*Rubia tinctorum sativa*, Linnæus), a plant which is cultivated in particular districts for the roots, which produce a fine red dye. It was formerly more extensively cultivated in England than it is now, when it can be imported at a less expense than it can be raised. It requires a very rich and deep soil, and much labour and attention, besides occupying the ground for three years before it comes to perfection.

Any soil which is deep and dry, and in which there is a good proportion of humus, will suit this plant. A rich loam, inclining to a sand, in which the roots can spread and swell, while they find sufficient nourishment, is preferable to the stiffer soils. If it has lain for a considerable time in grass before it is ploughed up, it will be all the better.

The preparatory tillage of the land must be such as to pulverise the soil to a great depth, and so mix the manure, which must be abundant, with every part, that, wherever the roots spread, they may find sufficient nourishment. The land is usually laid in beds, with deep intervals dug out with the spade, somewhat like asparagus beds. The width of these beds differs according to the natural moisture of the climate; in Belgium they are only three feet wide; and that width seems the best for a moist climate like that of England, except upon very light soils, where a greater width may be more advantageous. Trenching with the spade is generally preferred to ploughing, and is most economical in the end; for, however well and deep the land may be ploughed, it must be forked or dug over again several times before the plants are put in.

The manure used for madder must be well rotten and mixed with earth in a compost a considerable time before it is used. Good stable dung which has heated to a certain degree, and been turned over two or three times before it is mixed with earth, is the best. This earth should be sods taken from water-furrows in meadows and laid in a heap for some time. The dung should be put in layers with this earth, and if the whole can be well watered with urine or the drainings of the yard, and then mixed up by the spade, the compost will be much superior to fresh dung alone. This should be ploughed or dug in before winter. In spring another tillage may be given to destroy all weeds, [illegible] make the soil uniform to the depth of two feet at least. The land, having been harrowed flat, may now be laid into narrow beds by digging out the intervals with the spade; the surface being raked or harrowed smooth, the planting may begin.

The plants are raised in a seed-bed, or they are shoots and suckers from old plants. The first are a twelvemonth old from the sowing. The seed should be fresh; for if old seed is sown, it may not rise the first year. When a good variety of madder has been in cultivation, the shoots are preferred to seedlings; but when there is any appearance of the plants degenerating, a fresh sowing is had recourse to.

The suckers or shoots are taken off from the crown of old plants, when they have thrown out fibrous roots. They will then readily grow if transplanted. In southern climates this is done in autumn or winter, that they may not be scorched by the summer's heat. In northern climates June or July is the proper season, as there is never a deficiency of rain at that time. They may be also planted in February or March, if the ground is ready and dry: a showery time is advantageous. The plants are put in by means of a dibble, or rather a narrow trowel, which opens the soil, and then lets the earth fall upon the roots; a slight pressure sets them firmly in the ground. On a three-foot bed there are only two rows about 16 inches apart, and each 10 inches from the side. They are set by a line, from four to six inches from plant to plant in the rows. A watering with diluted urine, after sunset, greatly assists their taking root.

In some places the madder plants are put in with the plough. A deep furrow is drawn, and the plants are placed against the furrow slice turned up; the return of the plough covers them, and makes a fresh bed for the next row. This may do on very rich, dry, light loams, but would not be advisable in heavier and moister soils. At every eighth or tenth furrow a water-furrow should be ploughed out, and deepened with the spade: with these precautions the plants may thrive, and a great saving may be made in the labour when a considerable amount of madder is planted.

When the madder plants begin to grow, they must be well weeded and earthed up with the hoe. Liquid manure should be poured into the intervals, and the earth impregnated with it thrown around the plants.

The same attention to weeding and earthing up must be continued till the roots are fit to be taken up, which is in the third year.

The stems and leaves of madder are often cut as fodder for cattle, which are very fond of them: it is said that the colouring matter is so penetrating, that the bones of cattle fed on madder for a considerable time have been found tinged of a red colour. This practice however is not to be recommended, as it must injure the growth of the root, which is the valuable part. When the roots are taken up it is best done by means of a fork, so as not to break or cut them. The earth is loosened all around, and the roots laid bare. They are carefully taken out of the ground without breaking them, and laid on the surface to dry partially and become tough, after which they may be gathered into heaps under a shed, or protected from the weather by straw, if it be rainy. They are afterwards dried in a kiln, and are then fit to be sold to the dyers. If the quality is good, the root on being broken has a bright red colour verging towards purple. A yellow hue indicates inferiority. The produce of an acre of madder is from 10 to 20 cwt. If the rent and expenses of three years are taken into consideration, and the manure and labour required, it will be readily seen that unless the price be 4*l.* per cwt. it will not pay so well as a common crop of potatoes, carrots, or parsnips, which will not require so good a soil nor so much manure. This is a sufficient reason for the decrease of the cultivation of madder in England. In some particular instances great profits have been realised by madder; but the demand is limited, and the price fluctuates so much, that it is not a crop to be recommended, except in peculiar situations and circumstances.

Chemical and Colouring Properties of Madder.—The root is the only part of the plant used for the purpose of dyeing: it is subjected to the operations of picking, drying, freeing from the earth and epidermis, and powdering. The powder is of a yellowish-red colour, and contains three different colouring matters, two of which, *alizarin* and *purpurin*, are red, and one, *xanthin*, is yellow. *Alizarin* (from *alizari*, the Levant name for madder) is obtained by gradually mixing madder in fine powder with an equal weight of sulphuric acid, and allowing the mixture to remain for some days; by this all the vegetable products but alizarin are carbonized; the residue is to be washed with water to separate the acid, then dried, and treated first with alcohol to separate a little fatty matter, and afterwards with repeated portions of boiling alcohol, which dissolves the alizarin; this alcoholic solution is to be treated with water, the alcohol is to be separated by distillation, and the residual liquor being thrown on a filter, the alizarin remains on it.

The alizarin may also be separated from the charred mass after it has been washed with water and alcohol, and dried by exposing it to a temperature of about 480° Fahr.; the alizarin then sublimes, and condenses in long brilliant needles of a very fine red colour.

The properties of alizarin are—that it is inodorous, insipid, neutral to test papers, very slightly soluble in cold water, and but little is dissolved by it even when boiling; it dissolves in alcohol and æther in all proportions; the aqueous solution is of a pure rose-red colour, and the æthereal solution is of a fine golden yellow. Diluted acids do not dissolve it, but concentrated sulphuric acid readily takes it up, and the solution is of a blood-red colour, from which water throws down the alizarin; concentrated nitric acid decomposes it, but chlorine acts feebly upon it.

Ammonia, potash, and soda, and their carbonates, all dissolve alizarin, and yield with it solutions of a most beautiful violet colour. Alizarin combines readily with various tissues which have been mordanted, and forms with them very fixed colours, which resist even the action of soap and boiling water. It is stated to be composed of 20 hydrogen, 15 carbon, and 62 oxygen.

Purpurin.—In order to obtain this, madder-root is to be treated with a solution of carbonate of soda till it ceases to yield colouring matter; it is then to be washed, and treated for some hours with a hot solution of alum; a little sulphuric or hydrochloric acid is then to be added, which occasions a precipitate of a fine slightly-orange red colour; this, after being collected and washed on a filter, and treated with alcohol, yields a solution which, when subjected to distillation, deposits purpurin. The properties of this substance are—that it is but little soluble in water, whilst alcohol, especially when hot, and æther, both hot and cold, dissolve it readily; the alcoholic and æthereal solutions are of a brilliant cherry-red colour, and yield by spontaneous evaporation acicular crystals of four to five lines in length. This substance is distinguished from alizarin not only by difference of colour, but because it is soluble in a solution of alum, and insoluble in carbonate of soda and protochloride of tin; it dissolves in this last solution by the addition of a few drops of potash. The colours which it imparts to different tissues are of a reddish or purple tint, and are extremely brilliant, but less durable than those of alizarin.

Xanthin, or the yellow colouring matter of madder, is obtained by very tedious processes; it possesses the smell of the root, is very soluble in water and alcohol, but less so in æther. It forms red compounds with bases. Concentrated sulphuric acid renders a solution of xanthin green, and precipitates a powder of this colour, which is soluble in water. According to Berzelius it is most probably modified alizarin.

Madder yields colours of the greatest permanence. It is employed for dyeing linen and cotton red, and two kinds of it are fixed on cotton; one is called simply madder red, and the other, which possesses a much higher degree of lustre and fixedness, is called Turkey or Adrianople red, because it was for a long time obtained from the Levant. It does not afford a colour of sufficient brilliancy for dyeing on silk, and wool takes it with greater difficulty than cotton. It is also employed in calico printing and in the preparation of madder lakes.

Independently of the colouring principles above described madder contains lignin, gum, sugar, resin, a bitter substance, a vegetable acid, vegeto-animal matter, and salts.

Trade in Madder and Madder Roots.—The quantity of this dyeing stuff imported in its natural state and ground, in each of the ten years from 1829 to 1838, has been as follows:—

	Madder Root. Cwt.	Ground Madder. Cwt.	Total. Cwt.
1829	32,541	70,017	102,558
1830	37,074	51,624	88,698
1831	52,447	43,936	96,384
1832	54,449	79,435	133,884
1833	36,662	81,397	118,059
1834	80,296	72,003	152,299
1835	66,323	94,102	160,425
1836	85,251	108,906	194,157
1837	109,235	84,841	194,076
1838	73,669	97,447	171,116

Nearly the whole of these importations are obtained from Holland, France, and Turkey. In 1837, the latest year for which we have such particulars, there were brought from Holland 54,279 cwt., nearly all of which was ground; from France we received 102,374 cwt., of which about one-half was in the like state of preparation; and from Turkey 36,473 cwt. of the unprepared roots. Some small quantities are brought from Spain and Italy. Of late years we have received from 2000 to 3000 cwts. annually from India. The duty chargeable on consumption is 2s. per cwt. on the prepared madder, and 6d. per cwt. on the roots.

MADEIRA, an island situated in the Atlantic Ocean, between 32° 30′ and 32° 56′ N. lat., and 16° 40′ and 17° 16′ W. long., and about 400 miles from the north-western coast of Africa. It is nearly 35 miles long, and its greatest breadth nearly 20 miles. The area is said to be 320 square miles, or nearly that of Huntingdonshire.

This island is one mass of basalt, rising with a rather steep ascent from the south and from the north towards the interior, where the highest part of the mass runs from south of east to the north of west, between Cape de S. Lourenço on the east to Cape de Pargo on the west. This, the most elevated portion of the rock, rises to 4000 and 5000 feet; the Pico Ruivo, the highest summit, attains 5993 feet above the sea-level. Both declivities of the mountain-mass are furrowed by deep and generally narrow valleys and depressions, traversed by streams of clear water. These valleys contain the gardens and vineyards. The vineyards are formed on the declivities of the rocks, to the height of 2300 feet above the sea. The rocks in most places come down to the very shore of the sea, and enter it with so rapid a descent, that soundings are to be only found close to the shores, and even there on a rocky and unequal ground, and at a depth of 35 to 50 fathoms.

The climate of Madeira is very mild. The mean temperature of the year does not exceed 68°. In the months of December and January the thermometer rarely sinks below 60°; the mean temperature of that season being 63°. The mean temperature of the hottest months (August and September) is between 73° and 74°; but when the eastern and south-eastern winds bring to the island the hot air from the African desert, the thermometer sometimes rises as high as 82° and even 92°. Rain is not confined to a certain season of the year, but occurs at all seasons. Madeira sometimes suffers from hurricanes. The climate is considered very healthy, and many persons in England who are suffering from or in danger of consumption withdraw to it for the purpose of diminishing their sufferings and prolonging their life.

In the lowest region of the island, to about 750 feet above the sea-level, many tropical plants are cultivated, as the date palm-tree, the plantain, two kinds of cactus, the sweet potato, Indian corn, coffee, and the American agave (*Agave Americana*), as well as the sugar-cane, the olive-tree, the pomegranate, and the fig. Above this region, to a height of from 750 to 2300 or 2500 feet above the sea-level, the fruits and grain of Europe, especially wheat and maize, are raised; and in this region are also the extensive vineyards, which furnish the most important article of exportation. Then follows a tract covered with high trees, which rises to 3200 feet and higher, where many plants and trees are found which do not occur in Europe. This region contains also extensive forests of chestnut-trees, the fruit of which is the common food of the inhabitants. Its surface is extremely broken, and bare rocks appear in many places. The highest portion of the rocks is covered with heath, fern, and in some places with fine grass, which preserves its verdure through the greater part of the year, this region being frequently enveloped by dense fogs, and subject to heavy dews.

Few horses are kept, and most of them are imported. Cattle are more numerous, and of a large size. Asses are the most common domestic animals, and best adapted to the roads of the country as beasts of burden. Hogs are rather numerous, as well as fowls. In the interior there are many wild swine and rabbits. Birds are not numerous, and fish is rare, on account of the great depth of the sea which surrounds the island. Salted cod constitutes one of the most important articles of import.

Funchal, the capital, and the only town of the island, is on the southern coast. It has only an open roadstead, with a rocky and very uneven anchorage, in which vessels are exposed to great danger from November to February, when gales from the south-east and south-west prevail. Yet this place is frequently visited by ships bound to S. America, the Cape of Good Hope, or the E. Indies, as a place of refreshment, and from it all the produce of the island is exported. The town consists of a pretty wide street along the sea-shore, where there are several good buildings, and numerous small lanes, which extend to a considerable distance up the slope of the hill. The number of houses amounts to about 2000, and that of the inhabitants to 20,000. The town is defended by four forts, and has eight churches and several convents. In the midst of the town is an open square, planted with exotic trees, as Dracæna Draco, Jasminum azoricum, and Datura arborea.

The population of the island is estimated at 80,000, who are descendants of the Portuguese, but with a considerable mixture of African blood. The number of negro-slaves is still considerable, and was formerly much greater. The inhabitants are a very industrious and enterprising people.

The commerce of Madeira is considerable. The exports are stated to amount to 500,000*l.*, of which about 400,000*l.* in value go to England. The principal article is wine. During the late war, when the Spanish wines were not brought to England, 30,000 pipes were exported from Madeira, according to the statement of Lord Valentia. The importation of Madeira wine into England in 1833 was 301,057 imperial gallons. In 1825 the export was 14,425 pipes, and in 1826, 9391. The wine exported is Madeira wine and Malvasia de Madera. The latter is cultivated on the northern coast, near the village of Machico, and amounts to about one-sixth of the whole quantity exported. Minor articles of export are, fruits, dragon's-blood, honey, wax, orchil, a lichen collected from the rocks and used as a red dye, and tobacco, besides provisions for the vessels bound to more remote places. The imports consist of manufactured goods, corn, fish (herrings and cod), oil, salt-beef, salt, and some tropical productions.

Madeira is said to have been visited by Robert Machin, an Englishman, during the reign of Edward III. It was discovered in 1419 or 1420 by Gonzalves Zarco. It was then covered by an immense forest, whence its name is derived, Madera in Spanish signifying wood. The forest was set on fire, and it is said that the conflagration lasted seven years. Soon afterwards it was settled by the Portuguese, and the culture of sugar and wine was introduced. Sugar was grown to a considerable extent before the islands in the West Indies were settled; but upon that event the culture decreased, and was replaced by that of wine, which now seems to be giving way to coffee.

About 40 miles north-east of Madeira lies the small island of *Porto Santo*. It is a basalt rock, which does not exceed 500 feet in height. Indian corn and vegetables are cultivated for consumption, and a little wine for exportation. The population amounts to about 1200, of whom 600 live in the small town of Porto Santo, the roadstead of which is much exposed to southerly winds.

To the south-south-east of Cape St. Lourenço are three small basalt rocks, lying in a row from north to south. They are called *Ilhas Desertas*, and are only inhabited by sea-fowl, but they are visited from Madeira for the purpose of collecting the orchil, with which the greatest part of their surface is covered.

MADHOUSE. [LUNATIC ASYLUMS.]

MA'DIA, a genus of South American herbaceous plants of the Composite order, one of the species of which, M. sativa, is of value for the oil yielded by its seeds upon pressure. The genus forms the type of Madieæ, a division of the senecionideous tribe of De Candolle, and is distinguished among its congeners by its roundish one-rowed involucre, the bracts of which are keeled and envelop the grains, by a plane receptacle paleaceous at the margin and naked in the middle, and by its bald achænia, which have four or five angles, and taper to the base. **Madia sativa**, which forms the only species, is an upright hairy glandular viscid Chilian annual, with oblong entire leaves, half amplexicaul, opposite at the bottom of the stem and alternate at the top; the flower-heads are racemose, and the flowers pale yellow. It has long been cultivated in Chili, and apparently in California, for the sake of its oil, which is of excellent quality. It has lately attracted attention in Europe in consequence of Mr. Bosch, the superintendent of the gardens of the king of Wirtemberg, having successfully cultivated it in Germany on a large scale. He found that as compared with rape and poppies the amount of oil yielded per German acre was as follows:—

Rape	yields	240 lbs	of oil	per acre German.
Poppies	„	264 lbs.	„	„
Madia	„	442 lbs.	„	„

This oil does not congeal at 19° below zero of Réaumur, but only becomes a little less fluid, which makes it a valuable material for keeping machines in order. The seeds are sown in October, and from four to six pounds are required per acre (German). The crop is of the easiest management, and the only precaution to be taken by the cultivator, which it is important to notice, is that the seeds must be thrashed out soon after the crop is cut, otherwise the glutinous stalks, when heaped up, ferment and injure the seeds. (*Gardener's Magazine*, March, 1839, p. 142.)

MADISON, JAMES, was born on the 5th of March (o. s.), 1751, at the seat of his maternal grandmother, near Port Royal, on the Rappahannock river in Virginia. His parent's home however was then at Montpellier, in Orange County, Virginia, where Mr. Madison always resided.

He received his first instruction from Donald Robertson, a Scotch teacher in King and Queen County, Virginia, with whom he was placed at twelve years of age. During the three or four years that he was under Robertson's care he acquired some knowledge of Greek, Latin, and French, with the elements of mathematics. He afterwards studied about two years at home under the Rev. J. Martin. In 1769 he was sent to the college of Princeton in New Jersey, in preference to William and Mary College in Virginia, which was considered unhealthy to students from the upper parts of the country. In 1772 he took the degree of B.A., to obtain which however it was necessary to compress the studies, which usually occupy two years, into one, a circumstance which so much impaired his health, that it was thought advisable for him to remain in Princeton another winter. He returned to Virginia in the spring of 1773, and commenced a course of reading to prepare himself for the bar, but the dispute between the colonies and Great Britain having then commenced, he was soon induced to take an active part in it. He particularly distinguished himself as a friend to religious freedom by his efforts in behalf of the preachers of the Baptist persuasion, who were then persecuted with great zeal by the established church, and occasionally thrown into prison for preaching in defiance of prohibitory laws. In the spring of 1776 his political career commenced by his being chosen a member of the Virginia convention, which formed the first constitution of Virginia. He continued a member of the legislature till 1777, when he lost his election, in consequence, it is said, of his conscientious refusal to treat the freeholders, according to the practice then prevailing. The legislature however named him a member of the council, in which office he continued two years, until he was appointed a member of congress, in which body he took his seat in the month of March, 1780.

His letters and papers, which will shortly be published, show that he took a very active part in the proceedings of that body during the three years that he was a member of it.

Returning to private life after the peace, he resumed his legal studies, but intermingled them with miscellaneous and philosophical reading. Natural history, to which the genius of Buffon had then given unusual attraction, seemed to have been his favourite branch of science, and he has left some notes of his observations on European and American animals of the same species. In 1784 he was again elected to the legislature of Virginia, and continued a member of that body for the years 1785 and 1786. Here he formed the scheme, and drew up a resolution for that purpose, of inviting the meeting at Annapolis, which led the way to the convention that formed the constitution of the United States. He was one of the three commissioners from Virginia who assembled at Annapolis, where he met Alexander

Hamilton, with whom he was afterwards so closely united in framing the new constitution, and from whom he was so widely separated in carrying it into execution. It should be remarked that he did not offer the resolution which he had drawn up, on account of the jealousy even then entertained by state politicians of the federal authority and those who had been in congress, and it was confided to a member who was exempt from that suspicion.

While he was in the Virginia legislature he drew up the memorial and remonstrance against the project for a compulsory support of religion, which was perhaps made with a view to a permanent establishment; and he succeeded in defeating it. (Tucker's *Life of Jefferson*, chap. 4.) His talents and acknowledged influence at this time were all exerted in favour of a policy as liberal as it was practical and wise. Finding that Kentucky was determined to separate from Virginia, he furthered her purpose, instead of making a fruitless opposition to it. He opposed the attempt to introduce paper-money; he was the efficient supporter of the laws introduced into the code prepared by Jefferson, Wythe, and Pendleton; and he favoured the recovery of the debts due to British creditors. He proposed liberal donations to General Washington and to Thomas Paine: the latter effort failed; the former succeeded; but the donation was refused. He carried on an extensive correspondence at this time with some four or five friends, which gives the best view of the state of Virginia at that period. In the convention which formed the present constitution of the United States he bore a very conspicuous part; and anticipating the interest which future times would take in the proceedings of that body and in the opinions of its members, he was at the pains to keep a record of the debates, the only one extant which is either complete or authentic. He constantly wrote out at night what had been said in the day. After the constitution was formed, he united with Alexander Hamilton and John Jay in recommending it to the American people in newspaper essays, under the signature of Publius, which have been since published under the title of 'The Federalist.' The debates, which he would never consent to publish during his lifetime, congress have lately purchased for 30,000 dollars, and they will soon be published.

After the federal constitution was submitted to the several States for their adoption, Mr. Madison went into the legislature of Virginia, where Patrick Henry headed the opposition to it; and it was to Mr. Madison's cool and powerful reasoning that its adoption in that state was mainly due. If it had failed there, it would have failed altogether. Mr. Madison had also more agency than any other individual in inducing Virginia to make a cession of all her claims to the lands north-west of the Ohio (now comprehending the states of Ohio, Indiana, and Illinois), to which she asserted a right, both under her regal charters and by conquest during the Revolution.

He was chosen a member of the first congress under the constitution in 1789, and continued a member of that body until 1797. In 1794 he married Mrs. Todd, a widow of Philadelphia, whose parents were Virginians, but, being Quakers, had removed to Philadelphia. From this time he felt the strongest inclination to retire from public life, and to devote himself exclusively to the cultivation of letters and science, and the pursuits of agriculture. But his countrymen appreciated his worth too highly to permit him to retire into private life. In congress no one had more weight personally; but soon finding that his views and those of Mr. Hamilton did not coincide as to the principles and spirit in which the federal government should be administered, he separated himself from the administration, and was thus on most great measures in a minority. When the public debt was funded, he made an unavailing attempt to secure to the soldiers and other original creditors the benefit of the rise in value of the public claims, which speculators had purchased at about one-eighth of their nominal amount. This was the first great measure in which he opposed the ministerial policy of which Hamilton was the chief author. He also opposed the unqualified assumption of the state debts by the federal government. After the French revolution broke out, European politics mingled in those of the United States, and for a time gave them their chief form and colour. Mr. Madison, who always inclined to the side of liberal principles, was a warm friend of the Revolution; and though its excesses were more unexpected to no one than to himself, characterised as he was through life by mildness of temper, humanity, and love of order, yet he considered it as likely in the end to advance the cause of civil freedom, and it therefore had his hearty wishes for its success.

Though thus leading an organized opposition to General Washington's administration, this circumstance for a long time seemed to have no influence on their friendship, and it never produced positive alienation. Before his first term had expired, General Washington, being bent on retirement, conceived the purpose of a farewell address; and after making an outline of his views, he requested Mr. Madison to fill it up. Some years afterwards he greatly enlarged Mr. Madison's draft, which he then submitted to Messrs. Hamilton and Jay, and the document as published is found to contain some of Mr. Madison's original forms of expression. The intimacy and correspondence of these two great men continued until 1796.

After it was known that General Washington would retire in March, 1797, parties prepared themselves for the struggle of electing his successor, the federalists uniting in favour of Mr. Adams, and the republicans in favor of Mr. Jefferson. Mr. Adams succeeded by three votes. When parties were so nearly balanced, each redoubled its efforts for the ascendancy. The administration party prepared two laws for removing dangerous and suspicious aliens, and for punishing libels on the government (called Alien and Sedition Laws), which gave their adversaries a fit occasion to make a powerful appeal to the people. To further this object Mr. Madison, who was now withdrawn from congress, went into the Virginia legislature; and in the session of 1798 prepared resolutions denouncing those acts of congress as infractions of the constitution, and inviting the concurrence of the other States. As some of the States opposed the doctrines, and the subject produced much discussion in pamphlets, in the following year Mr. Madison prepared new resolutions, with a preamble, in which he examines the whole subject in one of the closest and profoundest pieces of reasoning which our language contains. It is thought to have contributed more than anything else to the revolution of parties which soon followed. This Report has since become a text-book for politicians on constitutional law and the relative rights of the States and general government. When Mr. Jefferson was elected president, Mr. Madison was made his secretary of state, and from that time until his retirement his life is comprehended in the history of the United States. But the principal parts which he acted will be briefly noticed here.

His pen was put in requisition in maintaining the claim of the United States to the right of deposit at New Orleans, under the treaty with Spain; in discussing the question of the true boundary of Louisiana; in corresponding with Mr. Rose and Mr. Jackson, ministers of Great Britain, on the subject of the attack on the Chesapeake; in drawing up instructions to Mr. Monroe concerning the treaty with England, and the objections to that which was made; and in corresponding with the American ministers on the French Decrees and British Orders in Council. Besides these official papers he wrote an 'Examination of the Doctrines of National Law' asserted by Mr. Stephens, which is perhaps the most compact piece of logic that he ever produced, and the most satisfactory exposition of the relative rights of neutrals and belligerents that is extant.

In 1809 he succeeded Mr. Jefferson as president of the United States; he obtained 122 votes out of 176. General Pinckney, of South Carolina, his opponent, obtained 47 votes. In Virginia the State appeared at first nearly divided between him and Mr. Monroe, but a majority of the legislature declaring informally a preference for Mr. Madison, the State followed their example.

It is known that after many fruitless efforts to induce Great Britain and France to respect neutral rights, war was declared against Great Britain during his administration, and that it continued with various success until 1815. It is said that Mr. Madison, being aware how unprepared the United States were for war, and anxious to preserve peace as long as it could be preserved consistently with the neutral rights of America, wished to postpone the declaration of war, but was urged into it by Mr. Clay and some ardent spirits whose patience was exhausted. If this be so, had his counsels prevailed, the war would have been prevented, for he has often told the writer of this notice that the administration had afterwards indubitable evidence that the British ministry had decided on revoking the offensive Orders in

Council, in which case the principal cause of war would have been removed.

After serving two terms Mr. Madison retired to private life, in March, 1817; and it may be questioned whether the eight years which he served as president were not the least happy of his life. In 1829, when the constitution of Virginia was submitted to revision, he consented to serve as a member of the convention, and no doubt contributed largely to soothe the irritation which the conflict of local interests created. He also acted as a visitor of the university of Virginia, and succeeded Mr. Jefferson as its rector. [JEFFERSON.] Except in the discharge of these duties, he not only held no office after his retirement, but, we believe, never left his county after he quitted Washington. Although Mr. Madison lived to the age of eighty-five, he had a very delicate constitution, and never enjoyed good health. He died on the 28th of June, 1836. His physician said that he had two or three diseases, any one of which was commonly sufficient to shorten life.

Montpellier, his patrimonial estate, is a large tract of good land in Orange County, from which there is a fine view of the Blue Ridge, about twenty miles distant. The house, a large brick building, with a Tuscan portico, was sufficient for himself and his father. He was much visited in his retirement. His character and former station attracted many visitors, and his almost juvenile spirits and delightful conversation, with the very pleasing manners of Mrs. Madison, often tempted his guests to protract their visits longer than they had intended. His visitors thus became a tax on his purse, which he very seriously felt, and which compelled him from time to time to sell portions of his land. Though he was incapable of giving an active superintendence to his farm, he managed it with great judgment and with tolerable success.

In person Mr. Madison was below the middle size; though his face was ordinarily homely, when he smiled it was so pleasing as to be almost handsome. His manner with strangers was reserved, which some regarded as pride, and others as coldness; but on further acquaintance these impressions were completely effaced. His temper seemed to be naturally a very sweet one, and to have been brought under complete control. When excited, he seldom showed any stronger indication of anger than a slight flush on the cheek. As a husband Mr. Madison was without reproach. He never had a child. He was an excellent master, and though he might have relieved himself from debt, and secured an easy income, he could never be induced to sell his slaves except for their own accommodation (to be with their wives or husbands). The writer has sometimes been struck with the conferences between him and some trusty servant in his sick chamber, the black seeming to identify himself with his master as to plans of management, and giving his opinions as freely, though not offensively, as if conversing with a brother. Mr. Madison has more than once told the writer that he should have been a great gainer in a pecuniary point of view if he had many years before emancipated his slaves. It was his deliberate conviction that the colonization of the slaves in Africa was practicable. He endeavoured to keep aloof from party feelings, but regularly read the newspapers, and remembered their contents better than most people. Though he was cautious in expressing his sentiments, he could not forbear taking the liveliest interest in public concerns, especially in those of the general government, towards which he seemed always to feel a parental solicitude. He stood well with all parties, and was solicitous so to stand, both from a sense of duty and a love of popularity. Of all the present public men Mr. Clay seemed to be his favourite. He felt great solicitude about the irritating discussions between the North and South on the subject of slavery, and remarked that Mr. Clay had been so successful in compromising great questions, he wished he could have done something on this; and then, he added, 'perhaps all parties would join and make him president.'

With great powers of argument he had a fine vein of humour; he abounded in anecdote, told his stories very well, and they had the advantage of being such as were never heard before, except perhaps from himself. But distrusting the infirmity of old age, he would often say, 'I believe I have told you this story before.' Such were his conversational powers that to the last his house was one of the most pleasant to visit, and his society the most delightful that can be imagined. Yet more than half his time he suffered bodily pain, and sometimes very acute pain. He left pecuniary legacies to some nephews and nieces; 1500 dollars to the university of Virginia, about 3000 or 4000 to the Colonization Society, and the rest of his property, in value above 100,000 dollars, to Mrs. Madison. His writings will be published in six volumes (exclusive of the Debates of the Convention): vol. i., Papers relative to the Old Confederation and Constitution of Virginia, Letters to Jefferson, Monroe, Washington, &c., down to 1789; ii., Letters to the same and others during the Administration of Washington and Adams; View of the Policy of these Administrations; Conversations with Washington, &c.; iii., Letters to Foreign Ministers, Heads of Departments, Presidents, &c., showing the Policy of the Jefferson and Monroe Administrations; iv., Letters and Writings on Constitutional Subjects; v., Essays and Letters on Political Economy, the Law of Nations, Natural History, &c.; and vi., Miscellaneous. (*Communication from Virginia.*)

MADOC, the second son of Owen Gwynnedd, prince of Wales, is said by some authors to have discovered America long before Columbus. The Welsh chronicles are said to state, that Madoc, having been compelled by civil disturbances to leave his native country, set sail in 1170 with a small fleet, and directing his course westward, landed after some weeks on a continent which produced abundantly the necessaries of life, and the inhabitants of which differed greatly from those of Europe. After remaining in the country a long time he left there 120 persons, and returned to Wales, where he equipped a fleet of ten vessels, and set sail again, but was never afterwards heard of. Some of those who adopt this narrative suppose Madoc to have landed on the coast of Virginia or Carolina, and support it by an account of the discovery of an Indian population in North America who spoke the Welsh language. If however there is any truth in the story, Madoc probably landed in a higher latitude than Virginia. See Filson's 'Discovery, Settlement, and present State of Kentucky; with an Account of the Indian Nations within the United States,' London, 1793, 8vo.; also Bertuch, 'Ephémérid. Géograph.,' September, 1819. The above narrative of Madoc's voyage (which has been copied by Hakluyt in the third vol. of his 'Voyages') is given in the 'Historie of Cambria, now called Wales, a part of the most famous Yland of Brytaine, written in the Brytish language, above 200 years past, by Caradoc; translated into English by H. Lloyd, gent.; corrected, augmented, and continued out of records and best approved authors, by David Powell,' London, 1584, 4to. Owen's 'British Remains' (London, 1777, 8vo.; 1785, 12mo.) contains 'An Account of the Discovery of America by the Welsh 300 years before the voyage of Columbus,' written by Dr. Plott. Herbert, in his 'Travels,' defends the claims of his countryman Madoc as the discoverer of the New World with more warmth perhaps than good sense. But the Northmen are said to have discovered America some time before the date of Madoc's alleged voyage; and this fact appears to be established by evidence of a much stronger kind than that of the expedition of the Welsh prince.

(*Biog. Univ.*; *Journal of the London Geog. Soc.*, vol. viii., p. 114.)

MADOX, THOMAS. Of the personal history of Madox little is known. He resided in the Middle Temple. He always writes from the Middle Temple. Thomas Madox of London was called to the bar by that Society in 1704, and the son of a clergyman of Wales of the same name, in 1705. His first work appeared in 1702, entitled 'Formulare Anglicanum; or a Collection of antient Charters and Instruments of divers kinds, taken from the originals, from the Norman Conquest to Henry VIII.': to which is prefixed a very learned dissertation on antient charters and instruments. In 1711 he published his great work, entitled 'The History and Antiquities of the Exchequer of the kings of England, in two periods: from the Norman Conquest to the end of the reign of King John; and from the end of the reign of King John to the end of the reign of Edward II., taken from records: together with a correct copy of the antient dialogue concerning the Exchequer, generally ascribed to Gervasius Tilburiensis; and a dissertation concerning the most antient great roll of the Exchequer, commonly styled the Roll of Quinto Regis Stephani.' This work, which was reprinted in two vols. quarto, with the valuable addition of an index, in 1769, begins with a dedication to the queen, followed by a long prefatory epistle to Lord Somers, in which the author says, 'The records which I here vouch were taken by my own pen from the authentick membranes, unless where it appeareth by my reference to be otherwise; and except lately in two or three instances, which it is not material to recollect; and in giving an account of the ancient state of the Exchequer, I have for the most part contrived, as far as the subject-matter would permit, to make use of such memorials as serve either to make known or to illustrate the ancient laws and usages of this kingdom; for which reason the present work may be deemed not only a history of the Exchequer, but likewise an apparatus towards a history of the ancient law of England.' This epistle concludes with 'a large digression concerning the Romanick dialect.'

The 'History of the Exchequer' treats of the court of the kings of England during the two periods comprised in it; its great officers, the jurisdiction of the king's exchequer, the matters and business of the exchequer of the Jews, showing the peculiar manner in which they were governed and protected as 'the king's villains;' of the different sources of the royal revenue, fully considered in all its branches; the whole illustrated by references to an immense mass of documents. The dialogue concerning the exchequer (which Mr. Madox ascribes to Richard Fitz-Nigel, bishop of London), treats, in the form of questions put to the author and his answers, of the functions of the different officers of the exchequer in the reign of Henry II., and of some other miscellaneous matters, in the first book, and of the mode of collecting the king's revenue in the second. It is preceded by an epistolary dissertation addressed to Lord Halifax. The dissertation with which the volume concludes, relating to the great roll of the exchequer, commonly called the roll of Quinto Stephani, is addressed to Lord Somers. It has lately been discovered by that eminent antiquarian the Rev. Joseph Hunter, that this roll ought to be referred to the 31 Henry I., a discovery which has removed some of the obscurity in which this part of the reign of Stephen is involved. Though Madox doubted whether this roll be referred to the reign of Henry I., Stephen, or Henry II., yet in his table of the barons of the exchequer from the Conquest, subjoined to the 'History of the Exchequer,' all who are placed in the list in the time of Stephen are so placed upon the supposition that it relates to the 5th year of that king, at which time many of those barons were and long had been the adherents of the rival claimant of the throne, the empress Maud.

In 1726 Mr. Madox published his 'Firma Burgi, or an Historical Essay concerning the cities, towns, and boroughs of England, taken from records.' A posthumous work from the pen of Mr. Madox, entitled 'Baronia Anglica,' a history of the land-honors and baronies, and tenure in capite, verified by records, in which he corrects the errors into which Lord Coke and others have fallen in the use of these terms [Manors], appeared in 1736, and with merely an alteration of the date in the frontispiece, in 1741.

Mr. Madox was indefatigable and successful in collecting his materials, and skilful in arranging them, but he has left it to others to apply them to the political and statistical history of the kingdom. A large body of documents, collected as materials for the works which he prepared for publication, and for others which he projected, were deposited by his widow in the British Museum.

Mr. Madox held the office of historiographer royal.

MADRAS, one of the presidencies into which the British empire in India is divided. It comprehends the whole of the peninsula of Hindustan south of the river Kistna, and some territory on the north side of that river acquired from the Nizam, and the province called the Northern Circars. The whole of this great territory, the area of which is upwards of 160,000 square miles, with nearly fourteen millions of inhabitants, is under the immediate government of the governor and council of Madras, but subordinate to the authority of the governor-general of India and his council.

The several districts contained within this presidency are —Northern Arcot, Southern Arcot, Bellary, Canara, Chingleput, Northern Circars, Coimbatore, Cuddapah, Dindigul, Ganjam, Guntoor, Masulipatam, Madura, Malabar, Nellore, Rajahmundry, Salem, Seringapatam, Shevagunga, Tanjore, Tinnevelly, Trichinopoly, and Vizagapatam.

The gross revenue collected within the presidency in the three years from 1833-34 to 1835-36 was as follows:—

1833-34	.	£3,378,209
1834-35	.	3,450,072
1835-36	.	3,500,201

The value of the imports and exports from and to all parts of the world in the year 1835 was—

Imports	.	£1,311,404
Exports	.	1,940,597

The greater part of this trade was maintained with the other British presidencies and Ceylon. The trade with Great Britain was valued at—

Imports	.	£344,681
Exports	.	192,764

MADRAS, or FORT ST. GEORGE, the capital of the southern part of British India, is situated on the Coromandel coast, on the Bay of Bengal, in 13° 5′ N. lat. and 80° 21′ E. long. Madras is in an open roadstead, and peculiarly ill adapted for a place of trade on account of the rapid current which runs along the coast, and the dangerous surf which beats against the shore. This surf is so violent that a peculiar kind of boat is necessarily employed for communicating between ships and the shore. These boats are large and very light; they are made by sewing planks together with straw between the seams, so that they yield to the shock without breaking when thrown upon the shore. They require to be managed with great dexterity by persons well experienced. Boats that belong to the ships, and which are built in the ordinary manner, are not allowed to approach nearer to the shore than the back of the surf, where they anchor and transfer their passengers or lading of goods to the Madras boats already described. In rough weather even these boats cannot venture out, and all intercourse with the shipping is stopped except by means of a contrivance called a catamaran, used by fishermen. These catamarans are made with two or three logs of light wood, each about ten feet long, lashed together. They are each managed by two men using paddles. It is very common for these men to be washed off from their vessel, which they regain by swimming. This is a service of much danger, not only for the reason just stated, but because of the sharks in the Bay of Bengal, by which the men are frequently attacked.

Fort St. George stands within a few yards of the sea. It was begun in 1639 by Mr. Francis Day, who obtained permission for the purpose from Sree Rung Rayeel. This fortress was soon surrounded by a town, which has since become very populous; the inhabitants in 1822 were ascertained to amount to 462,051. With the exception of one handsome street in the north-east quarter of the town, the whole is inhabited by natives. The street here mentioned contains the dwellings of Europeans, but the greater part of the English merchants and officers reside in what are called garden-houses in the neighbourhood of the city. The government-house is a handsome building, adjoining the esplanade. The native population for the most part reside in streets placed to the north and west of the fort, from which they are separated by a spacious esplanade.

Fort St. George was taken in 1746 by a French force under M. de la Bourdonnais, who obtained on that occasion a bounty of 640,000*l.* On this occasion every British inhabitant was compelled to leave the place. It was restored to the English at the peace of Aix-la-Chapelle. It was again attacked by the French under M. Lally in 1758, but after investing the fort for nine weeks they were obliged to raise the siege and retire with considerable loss. Madras has since been threatened with attacks by Hyder Ali in 1767 and 1781, but has never again been actually besieged.

Madras is 1030 miles from Calcutta, 758 from Bombay, 1185 from Agra, 1102 from Benares, 1275 from Delhi, 352 from Hydrabad, and 1661 from Lahore, all travelling distances.

MADRASTRÆA. This name is given by De Blainville to a subsection of the Madrephylliæa, including Astræa, Echinastræa, Oculina, and Branchastræa. He attaches but little importance to it as a division. [Madrephylliæa.]

MADREPHYLLIÆA, the first section of the Stony Zoantharia of Blainville, who styles the other section of this family of Zoantharia Madreporæa. The Linnæan genus Madrepora included nearly all the species, and obviously required analysis, the more so that geological naturalists referred to the same genus a vast number of previously unknown forms, and thus encumbered recent and imbedded fossil zoology, and prevented any right notion of the successive forms of zoophytic life on the globe.

Solander proposed some useful divisions of this unmanageable genus, derived from the growth of the animal;

Lamarck established many important genera, especially characterising some fossil groups; Lamouroux also laboured to improve the classification. Of late years Goldfuss has described additional fossil groups; and M. de Blainville has reorganised the labours of his predecessors, with a special regard to the soft animal parts figured and described by Lesueur, Quoi, Gaimard, and other voyagers.

The Madrephylliœa of this writer seldom acquire that highly ramose figure which belongs to the Lamarckian genera Madrepora, Pocillopora, &c.; they are furnished with cells of various figure, always however radiated by lamellæ, which are frequently numerous. There is no general distinctive character of the soft parts, or 'polypi,' as they have usually been termed.

GENERA.

Cyclolites (fossil).

Animal unknown; solidified by a calcareous *polyparium*, of a short, simple, orbicular, or elliptical figure, flattened, and marked with concentric lines below, convex above, with a great number of very fine entire lamellæ, convergent to a sublacunose centre.

Lamarck founded the genus; Goldfuss includes it with the Fungiæ. Only fossil species are known; they occur in the tertiary and upper secondary strata chiefly; Mr. Lonsdale notices it in the Silurian system.

Example. Cyclolites numismalis (Madrepora porpita, Linn.). Goldfuss, tab. 14, fig. 4, a, b.

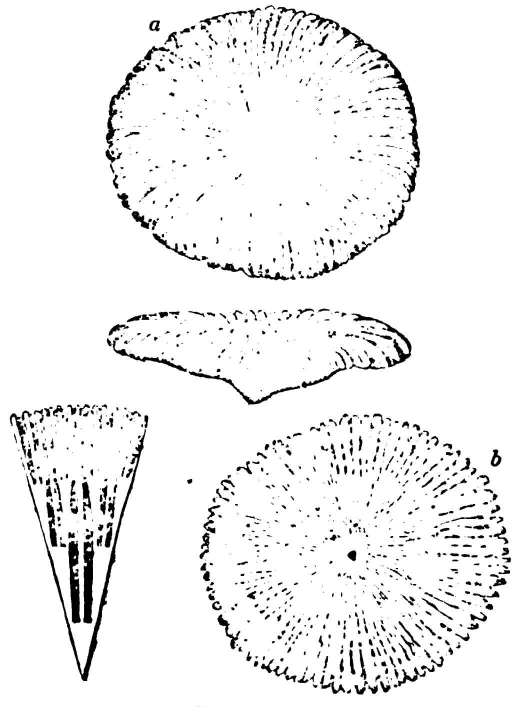
Montlivaltia (fossil).

Animal unknown; solidified by a calcareous *polyparium* of subconical or pyriform figure (fixed); transversely wrinkled below; enlarged, excavated, and lamellato-radiate above. From the oolite of Caen. Goldfuss refers it to Anthophyllum of Schweigger; and Blainville says it is closely allied to Cyclolites.

Example. Montlivaltia caryophyllata. Lamx., 'Zooph.' t. 79, figs. 8-10.

Fungia.

Animal gelatinous or membranous, generally simple, depressed, orbicular or oval; mouth superior, transverse in a large disk, which is covered by many thick cirriform tentacula; the disk is solidified internally by a calcareous solid *polyparium*, of a simple figure (seldom complex), ornamented above by a star of radiating aculeated lamellæ, and below by simple rugose rays.



Fungia patellaris.

a, upper face; *b*, lower face.

There are about nine recent (mostly from Indian Seas), and as many fossil species. Blainville arranges them in three groups: simple and circular; simple and compressed; complex and oblong.

The animal, according to Quoi and Gaimard, is very like that of Caryophyllia: it covers the upper face, and returns over the lower, so that the whole polyparium is internal. M. Stutchbury has described the growth of this coral in the 'Linnæan Transactions.'

Example. Fungia patellaris. Ellis and Soland., t. 2[illegible], figs. 1-4.

Polyphyllia.

Animals numerous, confluent, with a rather prominent mouth, lobed at the margin; numerous tentacula, not round the mouth, but scattered on the surface of a fleshy part, which entirely envelopes and encloses a calcareous solid *polyparium*. *Polyparium* a free, oval, elongated plate; above rather convex, and covered with lamellar ridges, which are denticulated, prominent, very slender, and transverse, but without stelliform disposition; below rather concave, and roughened by close-set tubercles.

The whole mass is free on the sea-bed.

Example. Fungia talpa of Lamarck. 'Actinologie,' pl. [illegible], fig. 1.

Anthophyllum.

Animal unknown, containing a calcareous *polyparium* of a conical or pyriform figure, fixed in the lower part, enlarged, flattened, excavated, and multilamellous in the upper part. This genus includes fossil species from antient rocks, and appears imperfectly distinguished from Turbinolia, unless the species of that genus were all free, which is at least doubtful.

Example. Anthophyllum Guettardi, Defr.

Note. Ehrenberg unites in one genus, Monomyces, the Anthophylla Montlivaltiæ, and the two first groups of Fungia.

Turbinolia.

Animal simple, conical, ribbed externally with larger and smaller ribs; terminated above by a mouth begirt with numerous tentacula, and solidified by a calcareous *polyparium*.

Polyparium free, conical, furrowed externally, attenuated to one extremity, enlarged at the other, and ending in a large shallow radiated cell.

Most of the species are fossil: they occur in rocks of all ages, particular species belonging to each; but if the genus is not very obscurely characterised, the use of the term is not very accurate. According to Blainville, the recent T. amicorum has twenty-four ribs; but this number is exceeded vastly in some of the fossil species referred to the genus; and in others there are fewer than twenty-four.

Diploctenium of Goldfuss is a compressed turbinolia, according to Blainville.

Example. Turbinolia amicorum, Bl. South Seas.

Turbinolopsis (fossil).

Animal unknown, solidified by a calcareous *polyparium*, of a simple turbinated figure, and free. This polyparium is lacunose, furnished above with radiating lamellæ, united at short equal intervals, and marked externally by longitudinal flexuous striæ, inclosing between their united edges vertical lines of pores or cells.

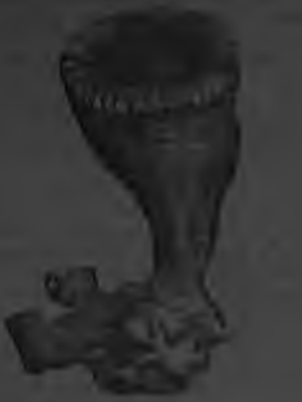
M. Lamouroux describes this genus. It has been recently adopted by Mr. Lonsdale for specimens which occur plentifully in strata below old red-sandstone. ('Silurian System,' by Murchison.) De Blainville appears to think it should be reunited with Turbinolia, but he had not examined the specimens noticed by Lamouroux.

Example. Turbinolia ochracea, Lamouroux. 'Gen. des Polyp.,' t. 82.

Caryophyllia.

Animals actiniform, subcylindrical, provided with a simple or double crown of short, thick, perforated tentacula, which project from the surface of stars or cylindriconical cells; cells furnished with radiating lamellæ internally complete, externally striated, and aggregated into a solid conical polyparium, fixed at the base. The species are grouped according to the simple or fasciculated character of the mass. There are both recent and fossil examples of each group.

Lamarck is the author of this genus, distinguishing it from Turbinolia and from Oculina: he has been followed by nearly all zoologists; but Goldfuss has reunited Caryophyllia and Oculina into his genus Lithodendron.



Caryophyllia cyathus.

Example. Caryophyllia cyathus. Ellis and Sol., t. 28, f. 7.

Ehrenberg divides this genus, and forms the following new genera:—

Desmophyllum.	*Example,*	C. dianthus.
Cyathina.	"	C. cyathus.
Cladocora.	"	C. calycularis.

Sarcinula.

Animals unknown, contained in cells at the end of long cylindrical tubes; cells lamelliferous, stelliform; tubes striated externally, parallel to the axis, united, by a cellular transverse mass, into a solid calcareous *polypparium*, whose upper and under surfaces are plane and parallel.

This genus established by Lamarck, includes both recent and fossil species. It seems to bear the same relation to Caryophyllia that certain tubular sections bear to the solitary forms of that genus. There is no sufficient reason for the conjecture of De Blainville, that 'Lithostrotion' of Lhwyd should be referred to this genus; it has more resemblance to the following group, with which indeed De Blainville has joined it.

Columnaria (fossil).

Animals unknown, contained in shallow, multi-radiate, stelliform *cells*, at the ends of polygonal tubes; tubes aggregated, contiguous, more or less parallel, forming by their union a solid, thick, calcareous *polypparium*.

This is a genus of Goldfuss, established on fossils of the 'Transition' strata.

Stylina (fossil).

Animals entirely unknown, contained in radiated cells at the end of long cylindrical vertical tubes; tubes furnished internally with distinct lamellæ, which radiate from a solid more or less prominent axis, and are united by a cellular mass so as to form a stony *polypparium*, more or less extended, thick, and subconvex above.

A genus of Lamarck (originally named *Fascicularia* by him), which includes perhaps only one species. The prominent axis occurs however in several madrepore fossils not usually referred to this genus—as certain *Cyathophylla* of Goldfuss. Sarcinula conoidea of this author is ranked by Blainville as a Stylina.

Catenipora (fossil).

Animals unknown, contained in tubular cells; cells terminal, often oval, *furnished with radiating plates*, and joined laterally into a calcareous *polypparium*, which may be described as of a conical figure fixed, composed of vertical anastomosed lamellæ.

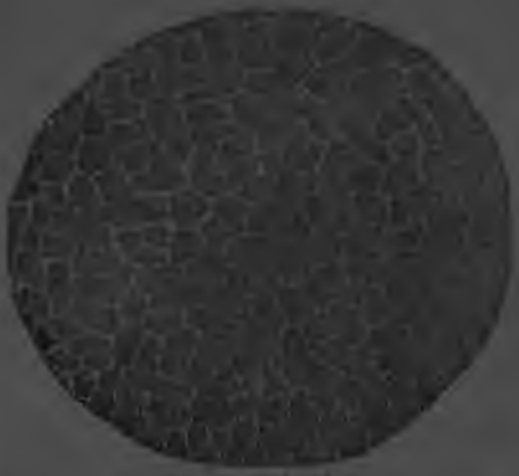
Tubipora catenulata of old writers is the type of this Lamarckian genus, which, with some surprise, we found to be, as Blainville states, really a lamelliferous coral. He drew this inference from examining a fine specimen, at Paris, of Catenipora escharoides, which he considers the only species. It is peculiar to the 'Transition' rocks, though not, perhaps, to the 'Silurian system.'

Example. Catenipora escharoides, Lamarck. Goldfuss, t. 25.

Fischer's genus Halysites is identical with Catenipora.

Syringopora (fossil).

Animals unknown, contained in long, subflexuous, tubular, vertical cells; opening of the cells round, terminal; numerous small horizontal tubuli branch off from the cells, and unite, by anastomosis, the whole cellular mass into one *polypparium*.



[illegible]

Goldfuss is the author of this genus, the species of which were, by older writers, always ranked as Tubipora. In our own examinations of Syringopora from the carboniferous limestone (S. ramulosa? Goldfuss), we have had reason to think the interior of the tubes had formerly been radiated, but the traces of the lamellæ are never clear, or even certain. The species belong to Silurian and carboniferous rocks chiefly, perhaps not exclusively.

Syringopora geniculata.

Examples. Syringopora verticillata. Goldfuss, t. 25, f. 6. S. geniculata. Phillips, 'Geol. of York.,' ii., t. 2, f. 1.

Dendrophyllia.

Animals actiniform, furnished with a great number of blind tentacula, in the midst of which is a polygonal mouth: the cells containing the animals are rather deep, and radiated by numerous prominent lamellæ; the *polypparium* which these compose is widely attached, arborescent, striated externally, lacunose internally, and truncate at the extremities. The species are both recent and fossil.

Example. Dendrophyllia ramea. Ell. and Soll., t. 38.

Lobophyllia.

Animals actiniform, furnished with many cylindrical tentacula; cells conical (sometimes elongated or sinuous),

with a subolpcular opening, laciniato-lamelliferous, terminating the few branches of the *polyparium*, which is fixed, of a turbinated shape, externally striated, and internally lacunose.

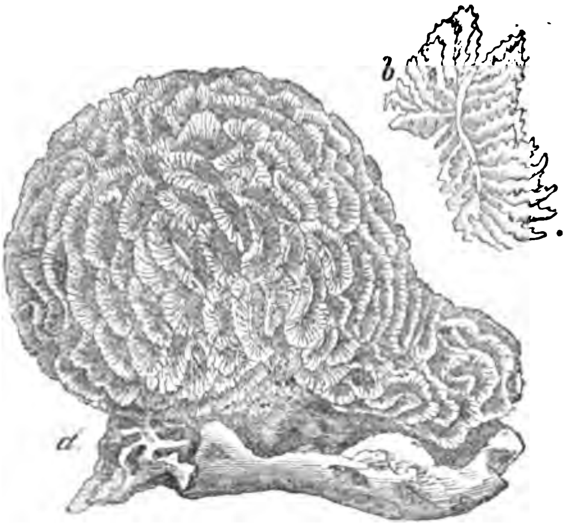
The species were included in Lamarck's genus Caryophyllia: the fossil species are chiefly from the oolitic formations.

Example. Lobophyllia carduus. (Caryophyllia carduus, Lamck.)

Meandrina.

Animals more or less confluent, in one surface, in long sinuous series, having each a distinct mouth and lateral series of very short tentacula, contained in shallow *cells*, which are not really separate, but form by their lateral union sinuous valleys; these valleys are furnished on each side of the mesial line with transverse subparallel lamellæ, ending against ridges which separate the valleys; the whole calcareous *polyparium* is fixed, simple, turbiniform when young, and globular when old.

This genus, established by Lamarck, is universally adopted by zoophytologists. The recent species belong to the Indian or South Atlantic Seas. The fossil species are few, and chiefly belong to the oolitic formation.



Meandrina dædalæa.
a, entire figure reduced; *b*, portion, nat. size.

Example. Meandrina dædalæa. Ellis and Sol., t. 46, f. 1.

Dictyophyllia (fossil).

Animals unknown, contained in polygonal, rather irregular *cells* of a considerable size; cells separated by partitions denticulated on both sides; the calcareous *polyparium* which results is fixed, deeply reticulated on the surface, and encrusts other bodies. (The base of the cells is finely tuberculated.)

The best marked species (D. reticulata) is found in the chalk of Maastricht. Goldfuss, t. 21, *fig.* 3.

Agaricia.

Animals wholly unknown, contained in cells, which often appear incomplete or confused, and sublamellar internally: they constitute by their union a stony *polyparium*, fixed, formed of flattened foliaceous irregular expansions, stelliferous on one side only.

The recent species are not numerous; we receive them from the Indian Ocean and South Sea. Goldfuss refers some fossils to this genus.

Example. Agaricia cucullata. Ellis and Sol., t. 42 f. 1, 2.

Tridacophyllia.

Animals actiniform, confluent, very depressed, enlarged, and attenuated to a finely crenulated edge; mouth central, a little tuberculous, *but without tentacula;* cells deep, irregular, foliaceous in the borders, lamellato-radiate, and denticulate within, externally and irregularly striated; the *polypiferous* mass thus formed is calcareous, foliaceous, not porous, striated, turbinated and fixed at the narrow part.

Lamarck included the principal species (T. lactuca) in his genus Pavonia; another he named Explanaria aspera.

Example. Tridacophyllia lactuca. **Ellis and Sol., t. 54.**

Monticularia.

Animals unknown, contained in cells *imperfectly circumscribed*, sometimes even confused or confluent; the lamellæ of these cells are very prominent, very distinct, rather numerous, and diverge from a tubercle; the union of the cells is marginal and in one surface; the *polyparium* is calcareous, very lacunose and polymorphous: sometimes it encrusts other bodies, is agglomerated into a heap, or spreads in sinuous expansions, striated externally.

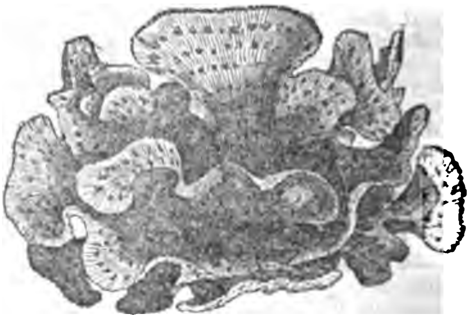
This genus of Lamarck is supposed to be identical with Hydnopora of Fischer. The recent species are from the Indian Seas. Mr. Lonsdale refers a fossil species of the Silurian system to this genus.

Example. Monticularia exesa. Sol. and Ellis, t. 49 f. 3.

Pavonia.

Animals without tentacula; the cells which contained them confluent, conical, small, rather oblique, furnished with many very close lamellæ disposed irregularly, though sometimes in series; the *polyparium* thus composed is solid, fixed, running into various agglomerations and expansions, with sharp edges.

The recent species are from the East and West Indian Seas. The few fossil species are from transition and oolitic formations.



Pavonia boletiformis.

Example. Pavonia boletiformis. Ellis and Sol., t. 32, f. 3, 4.

The following genera, viz.: Astræa, Echinastræa, Oculina, and Branchastræa, are grouped by De Blainville under the subsectional title of MADRASTRÆA :—

Astræa.

Animals short, more or less cylindrical; mouth rounded, placed in the midst of a disk covered with few and rather short tentacula; *cells* shallow, lamellæ radiating, and forming by their union a fixed polymorphous *polyparium*, which often encrusts other bodies, or is agglomerated on itself. This great genus is divided into sections.

Section A. *Astræoides* of Quoi and Gaimard.—Stars *round* and often disjoined.

Example. Astræa calycularis (*Caryophillia calycularis* of Lamarck). Mediterranean.

Section B. *Meandriniform Astrææ.*—Stars distinct, unequal, *oblong*, more or less *diffluent*, forming encrusting or agglomerated masses.

Example. Astræa uva.

Section C. *Gemmastræa.*—Stars *circular*, very *distinct*, *prominent*, and forming encrusting masses.

(These are chiefly fossil.)

Example. Astræa Lucasiana, Defr., from the oolite of Besançon.

Section D. *Tubastræa.*—Cells tubular, vertical, more or less distant, with a round opening, the edges being hardly prominent, and radiated by a moderate number (12 to 24) of *complete* lamellæ. This section includes many recent and fossil species.

Example. Astræa faveolata. Ellis and Sol., t. 53.

(The animal is described by Quoi and Gaimard.)

Section E.—Cells roundish, *approximate*, sometimes irregular, rather shallow; the lamellæ very dis-tinct, cutting, complete, *extended over the rounded interstices*; mass encrusting or agglomerated.

Astræa ananas.

Example. Astræa ananas. Ellis and Sol., t. 47.

Section F. *Siderastræa.*—Cells superficial or shallow, indefined, with numerous very fine lamellæ, radiating from an *excavated centre,* and continued to meet or even to join those of neighbouring cells.

Example. Astræa siderea. Ellis and Sol., t. 49.

The fossil species are numerous, especially in the later secondary and tertiary rocks.

Blainville makes several groups of them according to the manner of their growth.

Section G. *Dipsastræa.*—Of a globular figure; cells profound, infundibuliform, subpolygonal, contiguous, with common partitions, which are elevated, *sulcated,* and *echinulated* on the edges.

Example. Astræa dipsacea, Lamarck; Madrepora favosa, Ellis and Sol., t. 50.

There are fossil species in the secondary and tertiary strata.

Section H. *Montastræa.*—In thick masses composed of tubular cells, which acquire a polygonal figure from juxtaposition; their edges not prominent; the cavity not deep, furnished with numerous lamellæ united to a solid prominent axis. The known species are fossil.

Section I. *Favastræa.*—In a thick mass composed of large polygonal excavated cells, pluriradiate, depressed in the centre, and hollowed towards the margin. (*Acervularia* of Schweigger; *Cyathophyllum* of Goldfuss.)

Goldfuss's generic name is much employed for fossils of the Silurian rocks.

Example. Recent, Astræa magnifica. Indian Sea. Fossil, Astræa Baltica, Bl. (A. ananas, Linn.)

(Mr. Lonsdale has proposed a new genus, allied to *Cyathophyllum;* and from its vesicular internal structure calls it *Cystiphyllum.* From Silurian rocks.)

Section K. *Strombastræa.*—In corticiform masses composed of infundibuliform, polygonal, radiato-lamelliferous cells, which are proliferous, or succeed one another vertically. Goldfuss calls the group Strombodes. Its distinctness is doubted by Blainville.

Example. Strombodes pentagonus, Goldfuss. Fossil, in the North American limestone.

Section L. *Cellastræa.*—The species of this group differ from the Dipsastrææ principally by the fineness of their radiating lamellæ, and by a peculiar cellular structure. The fossil species are found in tertiary strata.

Example. Astræa incerta. Sol. and Ellis, t. 47, 3.

In concluding his examination of the great genus Astræa (which includes several other genera adopted by Goldfuss, Schweigger, &c.), De Blainville acknowledges the probable imperfection of the arrangement above given, and notices the transitions which it presents to the generic groups of Caryophyllia, Pavonia, Oculina, &c. Perhaps until the relation of the lamelliferous cells to their contained polypi is known from a very general investigation of recent types, zoologists will do wisely not to propose new genera from ill-understood specimens of antient corals.

Echinastræa.

Animals unknown, contained in raised cells which are strongly radiated, rather irregular, echinulated, and *occupy only the upper surface of the coral.* The mass is either fixed or free, expanded into a lobate or reflexed plate, internally echinated, striated, but not porous externally.

(Part of Explanaria, Lam., is included in this new group, as well as Echinophora of that author.)

Example. E. ringens, Lam.

Oculina.

Animals unknown, contained in regular, round, radiated cells, more or less prominent, and scattered on the surface of a solid, compact, arborescent, fixed polyparium. Lamarck established the genus; Schweigger has united it to Astræa, and Goldfuss to Caryophyllia.)

Oculina axillaris.

Example. Oculina axillaris. Ellis and Sol., t. 13, f. 5.

Branchastræa.

Animals unknown; the cells which contained them are of a cylindrical figure, channelled internally, prominent, radiating from the general mass, and united into a ramose, cylindrical, solid coral. Only one species, *B. limbata,* Goldfuss, t. 8, f. 7; from the Jura limestone, Suabia.

MADREPORÆA, the second section of the Stony Zoantharia of De Blainville, and placed by him after MADREPHYLLIÆA.

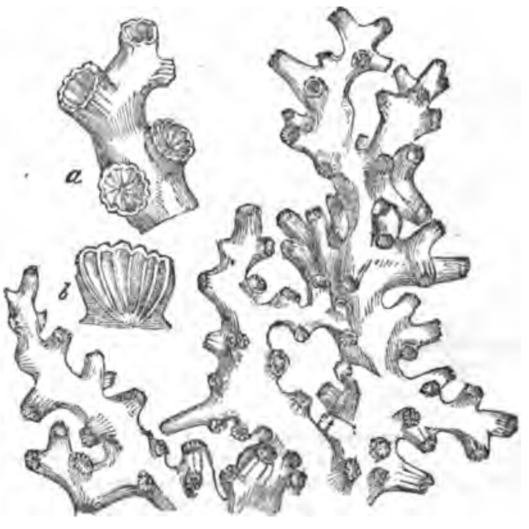
The Corals of this section are generally arborescent, with small partially lamelliferous cells, and constantly porous in the interstices and walls of the cells. This last is the most important character. The Lamarckian genus Madrepora included many of the genera of De Blainville.

GENERA.

Dentipora.

Animals unknown; cells deep, circular, mammillated, furnished with ten dentiform lamellæ prominent towards the margins, scattered in the *polyparium,* which is compact, expanded, its parts anastomosing together, and echinulated with strong interstitial tubercles.

The species are ranked with Oculina by Ehrenberg and earlier authors.



Dentipora virginea.
a, magnified; *b,* section of the lamelliferous cell.

Example. Dentipora virginea. Ellis and Sol., t. 36.

Astræopora.

Animals unknown (probably provided with a single crown of 12 tentacula): the cells which contained them are prominent, mammillary, internally sulcated, and irregularly scattered on the surface of the polyparium. Polyparium extremely porous and echinulated, enlarged into thin expansions.

Example. Astræa myriophthalma of Lamarck.

Sideropora.

Animals unknown; *cells* deep, immersed, circular or subhexagonal, with six deep notches at the border, and a prominent central axis, irregularly dispersed on the arborescent, palmated, finely granulated, but not porous *polyparium.*

(Several of Lamarck's Porites are placed in this group.)

Example. Sideropora digitata. In the Leyden Museum.

Stylopora.

Animals unknown; *cells* with few lobes at the circumference, internally striated, with a pistilliform axis, irregularly aggregated into an arborescent or subpalmated fixed polyparium, whose interstices are porous and echinulated.

(This group of Schweigger is not considered as really generic.)

Coscinopora.

Animals unknown; *cells* infundibuliform, quincuncial, forming the openings of capillary tubes laterally adherent into an attached, polymorphous polyparium.

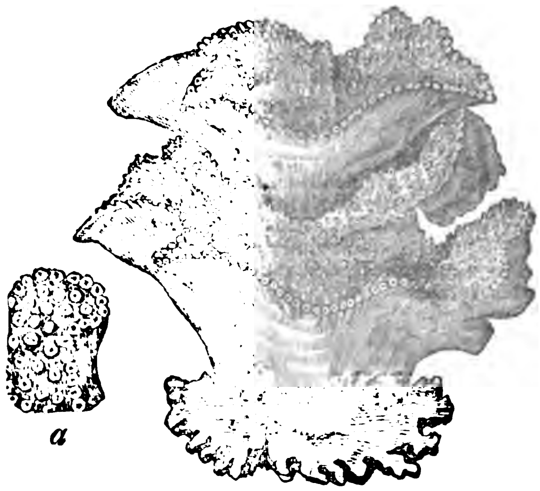
(This group, established by Goldfuss, is ranked by that author near to Retepora. There is apparently no evidence that it should be placed among the Madreporæa.)

Example. Coscinopora infundibuliformis. Goldf., pl. 9, and pl. 30, f. 10.

Gemmipora.

Animals without tentacula; *cells* deep, cylindrical, channelled, and almost lamelliferous within, *prominent in a mammillary form* on the surface of a fixed, porous, arborescent, or laminiform polyparium.

(Several of Lamarck's Explanariæ come into this group.)



Gemmipora mesenterina, diminished.
a, Portion, nat. size.

Example. G. mesenterina. Ellis and Sol., t. 43.

Montipora.

Animals actiniform, short, provided with small tentacula, to the number of twelve, placed in a single series; *cells* very small, rounded, impressed, regular, with few internal grooves. *Polyparium* incrusting or agglomerated, very porous, much echinulated, and marked by mammillary prominences on the free surface.

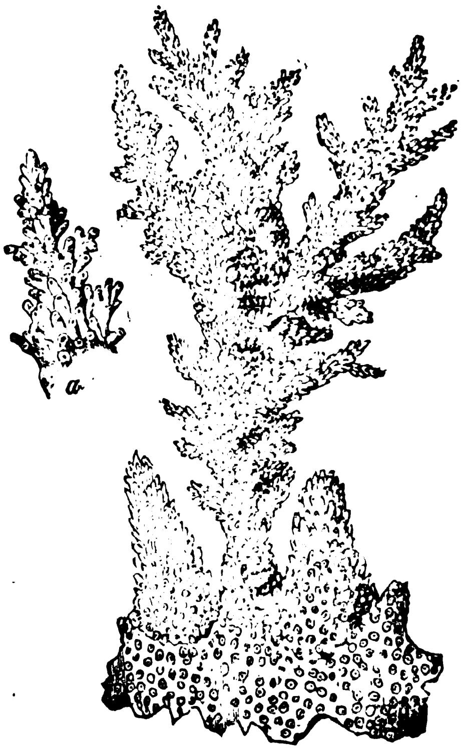
(Some of Lamarck's Porites are included in this genus.)

Example. Porites verrucosa, Lamck. Australasia.

Madrepora.

Animals actiniform, rather short, with twelve simple tentacula; *cells* deep, prominent, scarcely stelliferous, irregularly scattered on the surface, and accumulated towards the terminations of the polyparium, which is very porous, arborescent or frondescent, and fixed.

(This restricted genus includes several recent species, and a few fossils.)



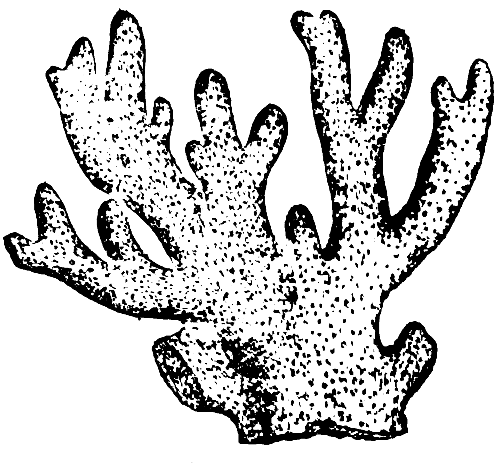
Madrepora abrotanoides, diminished.
a, Termination of one of the branches, nat. size.

Example. Madrepora abrotanoïdes, Lamck. Madrepora muricata, Linn. Ellis and Sol., t. 57.

Palmipora.

Animals unknown; *cells* very small, unequal, completely immersed, *obsoletely* radiated, scattered: polyparium fixed, cellular within, very finely porous and reticulated externally, expanded in a palmate or digitated form.

(The genus includes Millepora alcicornis of Linn. and others like it.)

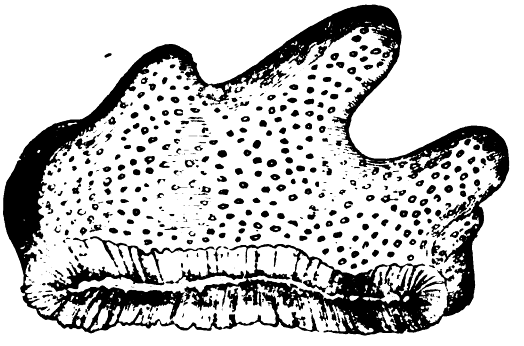


Millepora alcicornis.

Example. Millepora alcicornis, Linn.

Heliopora.

Animals short and cylindrical, with a crown of 15 or 16 broad and short tentacula; cells cylindrical, vertical or subdivergent, *immersed, internally crenulated* by partial lamellæ; polyparium largely porous in the interval of the cells.



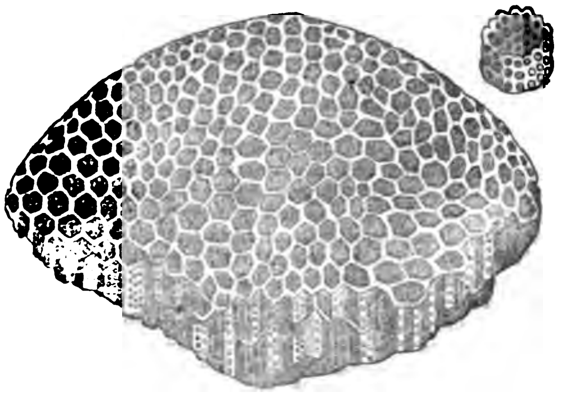
Heliopora cærulea.

Example. Heliopora cærulea. Madrepora cærulea. Ellis and Sol., t. 12, f. 4. Pocillopora cærulea, Lamck. From equatorial seas.

A fossil species in the transition limestone (astræa porosa, Gold.), usually ranked in this genus, is put in Porites by Ehrenberg and Lonsdale. (Murchison's 'Silurian Region.')

Alveopora.

Animals actiniform, with twelve simple tentacula; *cells* deep, polygonal, irregular, unequal, *internally tuberculiferous*, with perforated or reticulated parietes, echinulated on the terminal edges; polyparium porous, cellular.



Alveopora retepora.

Example. Alveopora retepora. Madrepora retepora, Linn. Ellis and Sol., t. 54, f. 3-5.

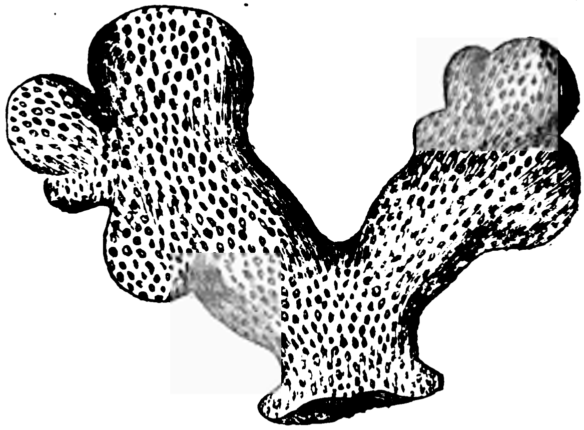
Goniopora.

Animals actiniform, elongated, cylindrical, with a crown of more than twelve simple tentacula; *cells* polygonal, internally sulcated, echinulated on the edges; polyparium extremely porous.

One recent species (G. pedunculata of Quoi and Gaimard).

Porites

Animals urceolate, with twelve very short tentacula; *cells* polygonal, unequal, imperfectly defined, incompletely radiated by filamentous pointed rays, with echinulated intervals; polyparium diversiform, porous and echinated.



Porites clavaris.

(A genus of Lamarck, but somewhat contracted by Blainville.)

Example. Porites clavaria, Lamck. Ellis and Sol., t. 47, f. 1.

Seriatopora.

Animals without tentacula?; *cells* immersed, ciliated on the edges, but not internally lamelliferous, ranged in longitudinal series on the cylindrical branches of a porous finely ramified polyparium.

(A genus of Lamarck, modified. It includes only a few species, much like the type, Madrepora *seriata*, Linn.: figured in Ellis and Sol., t. 31, f. 1-2.) Ehrenberg ranks them with Millepores.

Pocillopora.

Animals without tentacula?; *cells* small, shallow, subpolygonal, echinulated on the edges, and sometimes rather lamelliferous within; towards the terminations of the branching polyparium the cells are contiguous and adherent, but separated by granular interstices near the base of attachment. The polyparium is not porous.

(Lamarck established the genus, which is generally adopted. Ehrenberg doubts if there be any tentacula.)

Ex. P. damicornis, Lamck. Recent, in the Indian Sea.

MADREPORITE.—*Anthraconite; Columnar Carbonate of Lime.*—Occurs in roundish masses, the structure of which is columnar and diverging. Fracture indistinctly lamellar. Hardness 3·0; yields easily to the knife. Colour greyish-black. Lustre vitreous. Opaque, or only translucent on the edges. Specific gravity 2·7. It is found in Norway at Stavern, in transition rocks; at Gyphytta in alum slate; in Greenland, and in Salzburg.

Analysis by Klaproth:—

Carbonate of Lime	93·
Carbonate of Magnesia	10·30
Carbonate of Iron	1·25
Silica	4·50
Carbon	0·50
	99·55

MADRID, the capital of New Castile and of Spain, and now also of the province of Madrid, stands on a range of small hills rising in the middle of the extensive plain of New Castile, which is bounded on the north by the mountains of Guadarrama, and on the south by those of Toledo, in 40° 24′ 18″ N. lat., and 3° 42′ W. long. of Greenwich. Madrid is supposed to occupy the site of the Mantua Carpetanorum of the Romans, which was called Majoritum by the Goths, whence its present name Madrid is derived. Some antiquarians contend that it was so called by the Spanish Arabs, in whose language the word *Magerit* meant a 'well-aired house.'

During the occupation of the peninsula by the Arabs the place served as a frontier town, and its castle was often taken from the Arabs and retaken by them until 1086, when it was finally taken by Alphonso VI., the conqueror of Toledo, who annexed it to the bishopric of Toledo, to which it now belongs. It continued to be a mere village until the reign of Henry III. of Castile, who, being passionately fond of hunting the wild boar and the bear, both which animals were then abundant in the mountains near Madrid, made the place his residence during the hunting season. Charles V. occasionally lived in it, and it was at last made the capital of the Spanish dominions by his son Philip II., in opposition to the opinion of his ministers, who strongly advised him to fix his court at Lisbon.

Madrid is more than 2000 English feet above the level of the sea, a circumstance which accounts for the coldness of its winters. In summer the heat is excessive, in some measure owing to the want of trees in the neighbourhood. The thermometer in 1837 rose to 117° of Fahrenheit in the open air. In winter the same thermometer sometimes descends as low as 18°.

Madrid is on the left bank of the Manzanares, a small rivulet which has its rise in the mountains of Guadarrama, about 36 miles from the capital, and which, after flowing under the walls of Madrid, joins the Xarama, a considerable stream, at some distance from the capital. Two majestic bridges, called Puente de Toledo and Puente de Segovia, are thrown over the Manzanares; but such is the contrast between the imposing grandeur of these bridges and the scanty stream which flows beneath them, that it has given rise to the witty saying 'that the kings of Spain ought to sell the bridges, and purchase water with the money.' In winter however the heavy rains, and in spring the sudden melting of the snow on the neighbouring mountains, sometimes swell the Manzanares into an impetuous torrent.

Madrid is surrounded by a brick wall twenty feet high, which contains fifteen gates, mostly built of coarse grey granite. Among these the gate of Alcalá, and that of San Vicente, built in the reign of Charles III., and that of Toledo, erected in the reign of Ferdinand VII., are characterised by purity of design and solidity of structure. During the present civil war, some slight fortifications have been erected on the principal points leading to the city.

The general aspect of Madrid from all the approaches is anything but inviting. The numerous fantastic spires of churches and convents, the tiled roofs of the houses, the sterility of the neighbourhood, and the total absence of good houses, pleasure-gardens, or other buildings which indicate the approach to a great city, give to the capital of Spain the most gloomy and forbidding appearance.

The interior however is not devoid of beauty. The wide and well-paved streets, the extensive and well-planted public promenades in and near the city, with the fountains in many of the squares, the gorgeous churches, and handsome public buildings, remind the traveller that he is in the capital of Philip II. The houses are well constructed: the foundations and some of the ornamental parts are of granite, and the rest of red brick, stuccoed and generally painted. Each house is four or five, and frequently six stories high, and contains, as in Paris, several families. The principal streets, with few exceptions, are moderately wide and handsome: that of Alcalá, for instance, is wider than Portland-place in London, and contains many splendid buildings. The Calle Mayor, Carrera de San Geronimo, Calle de Atocha, &c., would be ornaments to any capital; the rest of the streets are generally narrow and crooked. There are 42 squares, of which the principal are—that of the Royal Palace; that of Santa Catalina, where a beautiful bronze statue of Cervantes has been lately placed; the Puerta del Sol, where the five principal streets of Madrid meet, and which is a place of resort both for the idle and the busy, being the spot where, owing to the proximity of the Exchange, or Bolsa, all commercial transactions are conducted in the open air; the Plaza de la Cevada, where criminals were formerly executed; and lastly, the Plaza Mayor, which is the finest of all. This square is now used as the rallying point for the garrison of Madrid in case of alarm, on account of the strength and solidity of the buildings and the difficulty of approaching it through the narrow crooked streets. Its form is quadrilateral, 434 feet by 334, and it is surrounded with stone buildings six stories high, ornamented with pillars of grey granite, which form a fine piazza all round.

The population of Madrid, as to which no official returns have been published since 1807, was stated by Miñano to be 201,344 in 1826, but this number is generally supposed to be too great for that time, although it may at present be nearly correct. The circumference of Madrid is not above five miles; and there are no suburbs.

The royal palace of Madrid, though unfinished, is one of the finest royal residences in Europe. The interior is decorated in a style of costly magnificence. It stands on the site of the old Alcazar, or palace, inhabited by Philip II., which was burnt to the ground in 1734. Philip V. began the building, which was continued by his successors. It has four fronts, 470 feet in length, and 100 feet high. The custom-house, a noble building, erected by Charles III., to whom Madrid is chiefly indebted for its embellishments; the Casa de Correos (Post-office) in the Puerta del Sol; the palace called de Buena Vista, formerly belonging to the dukes of Alba, now converted into an artillery museum; the royal printing-office in the street of Carretas, and the palace of the duke of Berwick, are among the public and private buildings which adorn the capital. Among the numerous churches and convents which fill the streets of Madrid, scarcely one can be mentioned as a specimen of a pure style of architecture. That of San Isidro, formerly belonging to the Jesuits, has a very fine portal; the convent of the Saleras, founded by Ferdinand VI. and his wife Barbara, is likewise a fine building, and the interior of the church is ornamented with the richest marbles. The convent of San Francisco el Grande, built in 1777, is justly admired for the severity and correctness of the design, its beautiful proportions, and a dome built in imitation of that of Saint Peter's at Rome.

There are 67 churches in Madrid, exclusive of private chapels. Before the year 1834 there were 66 convents, 34 for men and 32 for women. Some of them have been recently pulled down, either to widen the streets or to form squares; others have been converted into barracks, hospitals, magazines, and government offices.

Public promenades abound in Madrid. That which is most resorted to is the Prado, which consists of various alleys lined with double rows of trees, and ornamented with beautiful marble fountains. Adjoining to it is the Retiro, an extensive and beautiful garden. The garden suffered greatly, both from friends and foes, during the Peninsular war, but was restored by the late king, who added to it an extensive menagerie. Another favourite promenade is a vast plantation outside the gate of Atocha, called las Delicias, leading to a canal known by the name of Canal de Manzanares. This canal, which extends only six miles from Madrid, was intended to unite the capital with the river Tajo at Toledo, by means of the Xarama.

The literary and scientific establishments are generally of old date and insufficient to meet the wants of the present day. Miñano mentions 166 primary schools as existing in 1826, besides two colleges, both conducted by ecclesiastics. This number however has recently diminished. There are two extensive libraries open to the public; one founded by Philip V. in 1712, which contains 150,000 volumes, besides a very large collection of manuscripts, chiefly Greek, which have been described by J. Iriarte, and a museum of medals and antiquities. The library of San Isidro, belonged formerly to the Jesuits. Both have been considerably increased of late by the addition of the libraries of the suppressed convents within the capital. There are also four academies: 1, 'La Academia de la Lengua,' founded in 1724, in imitation of the Acadêmie Française, confines its labours to the publication of works in the Spanish language, such as grammars and dictionaries, and to editions of the best Spanish writers. 2, the Academy of History originated in a society of individuals whose first object was the preservation of historical records. It was confirmed by Philip V., who, in 1738, granted the present statutes. The labours of this body have been far more useful than those of its sister institution: and the nine volumes in quarto already published by them form a valuable addition to the history of Spain. 3, the Academy of the Fine Arts, instituted in 1738, holds weekly meetings at its rooms in the street of Alcalá, but it has hitherto done little or nothing: lastly, the Academy of Medicine. A fine botanical garden, well stocked with exotic plants, forms a delightful spot in the spring, when it is much frequented: attached to the establishment are various professors, who lecture upon botany, agriculture, and geology. The Museum of Natural History in the Calle de Alcalá is not worthy of the praise bestowed upon it by travellers: it certainly contains a splendid collection of minerals from the Spanish dominions in America, but they are badly arranged, and worse kept. It contains however the interesting skeleton of the Megatherium described by Cuvier.

Along the east side of the Prado is the National Gallery, a noble building of colossal dimensions, with a beautiful Tuscan portico and Doric colonnades. The collection of paintings which it contains has been lately pronounced by competent judges to possess a greater number of good pictures with fewer bad ones than any other gallery in Europe. The Armoury, a fine building of the time of Philip II., contains some of the most beautiful specimens of armour in Europe, especially of the *Cinque Cento*, or the fine times of Benvenuto Cellini. There are several complete suits of armour, which formerly belonged to Ferdinand V., Charles V., the Great Captain, John of Austria, Garcia de Paredes, and other illustrious Spaniards. The most interesting of all perhaps is a coat of mail with the name and the arms of Isabella upon it, which she is said to have worn in her campaigns against the Moors. An account of this collection, with drawings of the best pieces of armour, is now in course of publication.

Madrid has two small theatres, 'La Cruz' and 'Principe,' both managed by the Ayuntamiento, or municipal corporation, where Italian operas and Spanish plays are alternately acted. Another, of much larger dimensions, called the 'Teatro de Oriente,' has been lately built in the centre of the square, opposite to the royal palace, but is still unfinished for want of funds.

The inhabitants of Madrid repair, every Monday during the season, to a vast amphitheatre outside of the gate of Alcalá, where the favourite spectacle of bull-fights is exhibited.

The police of Madrid is not good. The streets are generally dirty, and the approaches to the city sometimes blocked up by heaps of rubbish. The city has no common sewers. Notwithstanding the great number of fountains, the want of good water is severely felt in summer. The city itself is considered to be extremely unhealthy; and if Philip II. chose it for his residence on account of the purity of the air and the quality of its waters, as we are told, Madrid must have undergone a complete change since that time. The sharp winds which blow from the Guadarrama mountains in winter produce the endemic pulmonia or pneumonia, which often proves fatal in a few hours. A sort of colic, caused by the dryness of the atmosphere, is likewise a prevalent complaint in summer.

Charitable and benevolent institutions are numerous, and some are amply provided with funds; but the management having always been in the hands of the clergy, the funds have been spent in building monasteries and churches, rather than applied to the charitable purposes intended by the donors. An institution, supported by voluntary contributions and patronised by the government, has recently been established outside of the city, for the reception of beggars, who were formerly objects of horror and disgust in the streets of Madrid.

On the 23rd of March, 1808, Madrid was entered by the French troops under Murat, and the royal family was decoyed into France. The heroic rising of the inhabitants of Madrid on the 2nd of May of the same year obliged the French to evacuate the town, and aroused the whole Spanish nation. Madrid was again occupied by Napoleon in person in December following, and by his brother Joseph in 1809.

Madrid has little manufacturing industry. A manufacture of porcelain and another of tapestry are both the property of the crown.

(Laborde's *View of Spain*, vol. iii.; *Viage Artistico á España*, vol. vi.; Miñano, *Diccionario Geográfico de España y Portugal*, vol. v.; Quintana, *Grandeza de Madrid*; Capt. Cook's *Sketches in Spain*; and chiefly, Mesonero, *Manual de Madrid*.)

MADRIGAL, in music, an unaccompanied vocal composition, sometimes in three parts, but commonly in more; and as the true madrigal is written in what is termed the learned style—abounding in points of the fugal or imitation kind—it is, almost necessarily, as much the produce of study as of genius. Morley—himself a renowned writer of madrigals—says that in this sort of composition 'no point is to be long stayed upon, but once or twice driven through all the parts, and sometimes reverted (inverted), and so to the close, then taking another. And that kind of handling points is most esteemed when two parts go one way, and two another way, and most commonly in tenths or thirds. Likewise the more variety of points be showed, the more is the madrigal esteemed; and withal you must bring in fine bindings (syncopations) and strange closes, according as your duty shall move you. Also in compositions of six parts (or five) you must have an especial care of causing your parts to give place one to another, which you cannot do without resting; nor can you cause them to rest till they have expressed that part of the ditty which they have begun.' (*Treatise*, 1597.)

The madrigal is to be traced to a very early period in the history of vocal music in parts: to the Flemings we are indebted for its birth, about the middle of the sixteenth century, and the Italians took it up shortly after, with what success the names of Palestrina, Marenzio, Converso, Ferretti, &c., will bear witness. Nor were the English deficient in emulation or slow in manifesting it; Morley's first book of madrigals was published in 1594, Weelkes's in 1597, Wilbye's in 1598, Bennet's in 1599, and only a few years later, John Ward's and Orlando Gibbons's appeared. Dowland's and Ford's lovely compositions, the former published in 1597, and the latter in 1607, have the title of madrigal bestowed on them, but they are more properly part-songs, or what would now be called glees. And here it may not be improper to say, that we are among the many who are of opinion that the English madrigalists have no superiors. To which we will add, that for the preservation of this high order of composition, the art has long been, and still continues to be, indebted to the *Madrigal Society*, a club, consisting chiefly of amateurs, founded in London in 1741, and which, by zeal and perseverance, has succeeded in diffusing throughout the British Isles a taste for a species of music as delightful as it is scientific, and exactly suited to the choral societies already existing, or springing up, in all our great manufacturing and commercial towns.

Every attempt to fix, with any precision, the derivation of this word, has been baffled. Menage thinks that *Mandra*, 'a sheep-fold,' is its source, for he supposes it to have been, in its origin, a pastoral song. Bishop Huet considers it a corruption of *Martegaux*, a name given to the inhabitants of a district of Provence, who, according to a learned French writer, excelled in the species of poetical composition called the *Madrigale*. Dr. Burney agrees with Doni, who derives it from *Alla Madre*, the first words of certain short hymns addressed to the Virgin. And Sir John Hawkins remarks, that there is a town in Spain named Madrigal. But all these conjectures—for they amount to no more—are merely plausible, and we only offer them in the absence of a more satisfactory etymology.

MADURA, an island in the Eastern seas, separated by a narrow strait from the north-east coast of Java. This strait is sufficiently deep to allow the largest ships to pass through, but the guidance of a pilot well acquainted with the navigation is required for that purpose. Madura lies between 6° 55′ and 7° 20′ S. lat., and between 110° 20′ and 111° 50′ E. long. Its extreme length from east to west is 90 miles, and its mean breadth 17 miles. The island is politically divided into three districts, each of which is nominally under the government of a native chief, but the whole are subject to the authority of the Dutch governor of Java. These divisions are:—Bangkalan, occupying the western; Pamakasan, the centre; and Sumanap, the eastern portions of the island. Each division contains a town or capital, bearing the name of the district. In the year 1746 the Dutch exercised so much authority over the chiefs or panumbahans of Madura, that they settled the order of succession, and obliged them to pay a tribute, partly in money and partly in the products of the country. For some services rendered to the Dutch government in 1825, during the insurrection in Java, the chief of Sumanap received the title of sultan.

The population of Madura in 1815, according to a census made by the English government, which was then in the possession of the island, was 218,659 souls, of whom 6344 were natives of China. The inhabitants reside in villages, of which there are about 1100 in the island. The character of the natives resembles very nearly that of their Javanese neighbours; but they are more warlike, and are more readily disciplined as soldiers: they speak a peculiar dialect, which has but little resemblance to that in use in Java. The religion of the Madurese is Brahminical, and the practice of widows burning themselves with the bodies of their husbands is prevalent.

The soil of Madura is fertile, and produces abundance of fine rice, part of which is exported to Java. Buffaloes and sheep are also bred for exportation, and a considerable quantity of cocoa-nut oil is also prepared for the same purpose; but the principal export-trade of the island consists of salt, many cargoes of which are taken every year to Java, Sumatra, and Borneo. (Stavorinus's *Voyages*; Crawfurd's *Indian Archipelago*.)

MÆANDER. [ANATOLIA.]

MÆCE'NAS, CAIUS CILNIUS, belonged to the equestrian order (Horat., *Carm.* i. 20, 5; Velleius Paterc., ii. 88; Tac., *Ann.* vi. 11), and was descended from an antient Etruscan family (Horat., *Carm.* i. 1, 1; iii. 29, 1; *Serm.* i. 6, 1) at Arretium. (Liv., x. 3.) The cognomen Mæcenas is derived, according to Varro, from a town of the same name. (*De Ling. Lat.*, vii., *end.*) We are ignorant of the place and time of his birth; but he appears to have received a superior education, and was well acquainted with the Greek language. (Hor., *Carm.* iii. 8, 5; *Epist.* i. 19, 1.) He early became acquainted with Octavianus (Augustus Cæsar), and continued through his life an intimate friend and chief adviser of that emperor. While Augustus was engaged in opposing Sextus Pompeius, and also during many of his other wars, Mæcenas was entrusted with the charge of the city; and it appears to have been owing in a great degree to his prudence and sagacity that peace was preserved in Rome during the absence of Augustus. (Tac., *Ann.*, vi. 11; Dio, xlix. 16; Senec., *Epist.* 114; Hor., *Carm.*, iii. 29, 25; and LEPIDI.) Mæcenas is said to have distinguished

Augustus from his purpose of restoring the antient Roman constitution, which Augustus however could never have seriously intended. (Sueton., *Octav.*, 28; Seneca, *De Brev. Vit.*, 5.) Mæcenas was held in the greatest honour by Augustus, although during the latter part of his life he appears to have been for a short time in disgrace with the emperor, principally owing to the intrigues of his wife Terentia (Tac., *Ann.*, iii. 30; Dio., liv. 19, lv. 7); but he was probably received into favour again before his death, which happened B.C. 8, four years after that of Agrippa. Mæcenas enjoyed with Agrippa the full confidence of Augustus, and his death was considered by Augustus as an irreparable loss. (Seneca, *De Benefi.*, vi. 32.) If we may believe a tale related by Dion, he sometimes rebuked the emperor with the utmost freedom (lv. 7).

Mæcenas was a great patron of literature; and it was principally owing to his assistance and support that Virgil and Horace were raised from a state of poverty and indigence, and enabled to devote themselves to poetry. They were both admitted to his friendship, and Horace in particular appears to have lived on terms of the greatest intimacy with him.

The health of Mæcenas was not good (Pliny, *H. N.*, vii. 52), and was probably injured by his luxurious and voluptuous habits. (Sen., *Epist.* 120; Juv., xii. 39; Petron., 81; Dio., liv. 30; Tac., *Ann.*, i. 54; Plutarch, *Erotica*, c. 16.) He lived in a magnificent house on the Esquiline Hill, from which Nero is said to have witnessed the burning of Rome. (Suet., *Nero*, c. 38; Sen., *Epist.* 114.)

Mæcenas wrote several works, none of which have come down to us. Their loss however is not much to be deplored, since, according to the testimony of many antient writers, they were written in a very artificial and affected manner. (Suet., *Octav.*, c. 86; Sen., *Epist.* 114; Tac., *Dial. de Orat.*, c. 26, who speaks of the *calamistros Mæcenatis*.) They consisted of poems, tragedies (one entitled 'Prometheus,' and another 'Octavia'), a history of the wars of Augustus (Hor., *Carm.* ii. 12, 9), and a symposium, in which Virgil and Horace were introduced. (Servius on Virg. *Æn.*, viii. 310.) The few fragments which remain of these works have been collected and published by Lion under the title of 'Mæcenatiana, sive de C. Cilnii Mæcenatis Vita et Moribus,' Göttingen, 1824.

There is a curious passage in the 'Saturnalia' of Macrobius (ii. 4), in which he gives an extract of a letter from Augustus to Mæcenas, in which the emperor ridicules the style of his friend: 'Vale, mel gentium, melcule, ebur ex Etrutria, lafer (lacer?) Aretinum, adamas supernas, Tiberinum margaritum, Cilniorum smaragde, jaspis figulorum, berylle Porsenæ, carbunculum habeas, *ἵνα συντέμω πάντα μάλαγμα* (*ἵνα συντείνω πάντα μαλάγματα*?) mœcharum.'

MAELSTROM. [TRONDHEIM.]

MÆNU'RA, or MENU'RA, Dr. Shaw's and Dr. Latham's name for a singular genus of birds, whose place in the system has occasioned some difference of opinion among ornithologists.

In 'An Account of the English Colony of New South Wales, from its first settlement in January, 1788, to August, 1801, &c. &c., to which are added some particulars of New Zealand, compiled by permission from the MSS. of Lieut.-Governor King; and an Account of a Voyage by Captain Flinders and Mr. Bass, &c. &c., abstracted from the Journal of Mr. Bass, by Lieut. Collins of the Royal Marines,' &c. (4to. 2 vols., 1802, London), it appears that in January, 1798, in consequence of the determination of certain Irishmen to go out for the discovery of a settlement for themselves, the governor, after ineffectually trying corporal punishment, determined, with a view of checking the spirit of emigration, to convince these Irish by their own experience of the danger and difficulties which attended it, and accordingly he caused four of the strongest and hardiest among them to be chosen by themselves, and properly prepared for a journey of discovery. They were to be accompanied by three men, upon whom the governor knew he could depend, and who were to lead them back when fatigued and exhausted with their journey over the worst and most dangerous part of the country. A conspiracy to murder the guides was discovered, and counteracted by the addition of four soldiers to the guides, and on the 14th they set off from Paramatta. On the 24th the soldiers returned with three of the deputies, who, having gained the foot of the first mountains, were so completely sick of the journey, and of the prospect before them, that they requested to return with the soldiers, whose mission here terminated. The three persons who had been sent out with the Irishmen returned on the 9th of February. 'On arranging their courses and distances on paper, they appeared to have travelled in a direction south-west three-fourths west about 140 miles from Paramatta. They brought in with them one of the birds which they had named pheasants, but which, on examination, appeared to be a variety of the Bird of Paradise. The size of this curious and handsome bird was that of a common hen; the colour a reddish-black, the bill long, the legs black and very strong. The tail, about two feet in length, was formed of several feathers, two of which were the principal, having the interior sides scalloped alternately of a deeper or lighter reddish-brown inclining to orange, shading gently into a white or silver colour next the stem, crossing each other, and at the very extremity terminating in a broad black round finishing. The difference of colour in the scallops did not proceed from any precise change in the colour itself, but from the texture of the feather, which was alternately thicker and thinner. The fibres of the outer side of the stem were narrow, and of a lead colour. Two other feathers of equal length, and of a blueish or lead colour, lay within those; very narrow, and having fibres only on one side of the stem. Many other feathers of the same length lay within those again, which were of a pale greyish colour, and of the most delicate texture, resembling more the skeleton of a feather than a perfect one.' Lieut. Collins then gives a figure of the bird 'from the pencil of a capital artist,' which seems to have been handed down from author to author, and is indeed upon the whole correct, with the name of *Mænura superba*.

M. Temminck arranged the form under his order of Insectivorous Birds (*Insectivores*), among the Thrushes, giving it a position between *Cinclus* and *Pitta*.

Cuvier does not differ much in his views from M. Temminck; for he places it among his great group of *Passereaux* (Cuvier's 2nd order), and it stands in the 'Règne Animal' in the following relative position: '*Oriolus*, *Gymnops*, *Mænura*, *Motacilla*.'

M. Vieillot differs almost entirely from both Temminck and Cuvier; for, though he includes it in his second order, which corresponds with the *Insessores* of Mr. Vigors, the *Lyriferi* stand in M. Vieillot's 'Analyse' at the extremity of that order, and near the groups of *Columba* and *Penelope*.

Illiger, in his *Prodromus*, arranged it among the *Rasores*.

Before we proceed to a consideration of the views of more modern authors, it is right to put the reader in possession of Cuvier's description, with his reasons for classing *Mænura* as he did. He says that the size of the bird (a little less than that of a common pheasant) has caused it to be referred to the Gallinaceous Birds, but that it belongs evidently to the Passerine order from its feet, whose toes (excepting the first articulation of the external and middle toe) are separated, while the form approaches the Thrushes (*Merles*) in the structure of the bill, which is triangular at its base, elongated, and a little compressed, and notched towards its point; the membranous nostrils are large and partially covered with feathers as in the Jays. *Mænura*, he adds, is to be distinguished by the great tail of the male, which is very remarkable for the three sorts of feathers that compose it. The twelve ordinary feathers are very long, with loose and very distant barbs; two more in the middle are furnished on one side only with close-set barbs, and two external ones are curved in the form of an S, or like the branches of a lyre, whose internal barbs, which are large and close-set, represent a broad ribbon, while the external ones are very short and do not become enlarged till towards the end of the feathers. The female has only twelve feathers of the ordinary structure.

Mr. Vigors (*Linn. Trans.*, vol. xiv.), who alludes to the position assigned to the bird by the authors above mentioned, places it at the extreme of his third order (*Rasores*), among his family of *Cracidæ*, for reasons which the reader will find stated in a former volume. [CRACIDÆ, vol. viii., p. 128.]

M. Lesson speaks of the position of the *Mænura* as far from being fixed, and though he follows Cuvier in placing it among the *Passereaux*, he observes that some authors think that it would stand better at the side of *Megapodius*, in the Gallinaceous order. After quoting the words of Cuvier given above, he says, 'The Mænura has then been arranged sometimes among the gallinaceous birds under the name of the *Lyre-Pheasant* or *Pheasant of the Woods*, and sometimes at the end of the *Colious* [HONEY-EATER, vol. xii.] and the *Pipras* (CHATTERER, vol. vii., p. 120), as M. Vieillot placed it, while, scientifically speaking, it is near the *Thrushes* that *Mænura* ought to take its place, though it departs distinctly from them in the form of the body.'

Mr. Swainson ('Classification of Birds,' vol. ii., 1837) alludes to the place assigned to *Mænura* and *Megapodius* by Mr. Vigors, and says that they certainly accord more with that family than with any other group of the Gallinaceæ. Mr. Swainson observes that both these genera have the feet uncommonly large, and that both seem to represent the rasorial genus *Orthonyx*, a bird indeed scarcely larger than a sparrow, but agreeing in the very remarkable rasorial character of having the three fore toes of nearly the same size. 'If,' continues Mr. Swainson, 'the *Cracidæ*, as we believe, is the scansorial family of the *Rasores*, this singular analogy is precisely what we should expect in two groups representing the same tribes.' In the synopsis at the end of the volume Mr. Swainson cancels the term *Cracidæ*, and substitutes in its place the family *Megapodinæ* (Megapodidæ?), remarking, that as he has every reason to believe, from an attentive study of this family, that *Crax* is an aberrant genus, he has thought it better to correct his former error, and to name the whole from that group which is one of the chief types; and he makes *Mænura* the first genus of his 'Family *Megapodinæ*, *Greatfoots*,' with the following

Generic Character.—*Bill* moderate, depressed at the base, straight; the tip obsoletely notched. *Nostrils* naked and placed near the middle of the bill. *Feet* very large, strong and robust; nearly all the anterior toes equal; the claws enormous for the size of the bird, obtuse, and slightly curved. *Wings* short. *Tail* very long, lyre-shaped; the feathers singularly developed. The typical or conirostral form of the whole family.

Example, *Mænura superba*. *Mænura Lyra* or *Lyrata*, *Mænura Novæ Hollandiæ*, Shaw, Lath., *Mænura paradisea*,* Vieill., the only species known.

Description.—Lieutenant Collins, in the work above quoted, gives, towards the end of his second volume, 'a more minute and ornithological' description (with which he had been 'favoured') than that stated above. The second description is as follows. 'The bill of this bird, which has been named the *Mænura superba*, is straight, having the nostrils in the centre of the beak. The base of the upper mandible is furnished with hairs like feathers turning down; the upper mandible is at the base, somewhat like that of the pigeon. The eye is a dark hazel, with a bare space round it. The throat and chin are of a dark rufous colour; the rest, with the body, of a dusky grey. The feathers on the rump are longer than those of the body, and more divided. The colour of the wings, which are concave, is dark rufous. The legs and claws are large in proportion to the bird, particularly the claws. The outward toe is connected with the middle one as far as the first joint. The tail is long, and composed of three different sorts of feathers, of which the upper side is of a dark grey, with ferruginous spots. The first two lower feathers, which are a little curved in two directions, are beneath of a pearly colour, embellished with several crescent-shaped spaces, of a rich rufous and black colour. The laminæ are unwebbed, turned round toward the extremity, and ornamented with a black bar the breadth of an inch, and fringed at the end. The shaft of the second, which is likewise long, is fringed with long hair-like filaments; and the third, which is also long and curved, is plumed on the inner side only, except at the extremity, where there are a few separated filaments of a dark-grey colour.'

'The female *Mænura superba* differs very little from the male, except in the tail, which is composed of twelve feathers, a little curved and plumed, having the upper side dark rufous and grey, and the under of a pearly colour.'

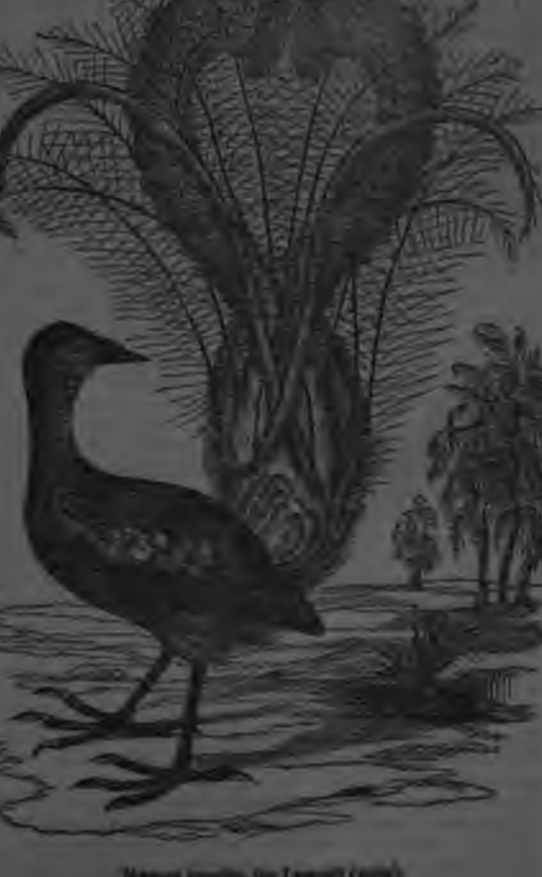
The more modern descriptions of the tail of the female state it to be simply brown, and composed of long uniform feathers, which are straight and graduated.

Notwithstanding the sombre hues of this extraordinary bird, the magnificence and peculiar structure of the beautiful tail of the male, which imitates the form of an antient Grecian lyre, gave it a superb appearance.

Locality.—New South Wales, principally in the forests of *Eucalyptus* and *Casuarina* which cover the Blue Mountains, and in their rocky and retired avenues.

Habits.—Lieutenant Collins says that 'the following particulars relating to these birds were observed by persons resident in the country, and who were eye-witnesses of what is here told. They frequent retired and inaccessible parts of the interior; have been seen to run remarkably fast, but their tails are so cumbrous that they cannot fly in a direct line. They sing for two hours in the morning, beginning from the time when they quit the valley, until they attain the summit of the hill, where they scrape together a small hillock with their tail spread over them, imitating successively the note of every bird known in the country. They then return to the valley.' If dependence could be placed upon this account as far as relates to the singing, it would assist the views of those who would place *Mænura* near the Thrushes; among the gallinaceous birds, singing, in the common acceptation of the word as applied to birds, is not known. But this sort of statements, taken as they mostly are from the relation of those who are not very careful as to the truth of their communications, if they can only surprise and please their auditors, must be received with many grains of allowance. The 'song' is not corroborated by subsequent observers.

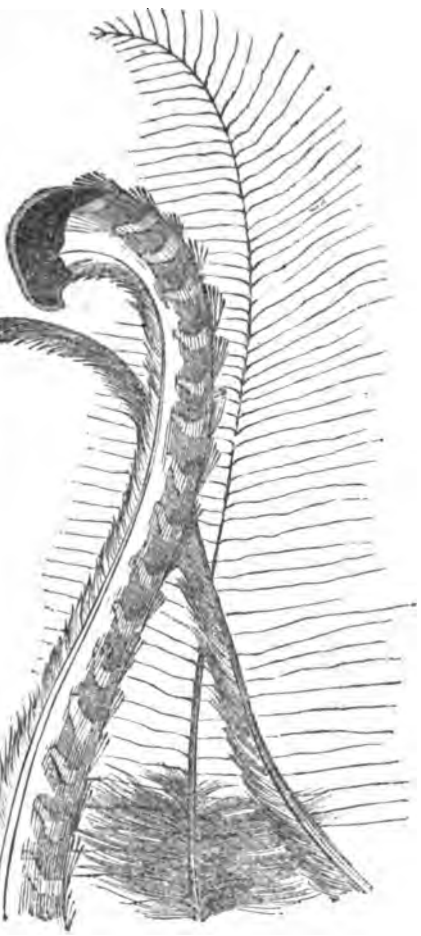
Mr. Caley informed Mr. Vigors, that from the observations he was enabled to make on these birds during his stay in New Holland, it was his opinion that these birds were gallinaceous. Mr. Caley generally found them in flocks, and for the most part on the ground. M. Lesson states that they come forth in the evening and the morning, remaining quiet during the day on the trees whereon they perch. He says that they are becoming more and more rare, and that he only saw two skins during the whole of his stay at New South Wales. Mr. Swainson informs us that chief-justice Field of Gibraltar, who was long a resident in New Holland, assured him (Mr. S.) that *Mænura* in all its habits was a gallinaceous bird, living on the ground in small societies, and being very fond of rolling in the dust.



Mænura superba, the Lyre-tail (male).

---

* This is the name adopted by Mr. Swainson.



Some of the tail-feathers of Mænura superba.

Mr. Bennett in his 'Wanderings in New South Wales,' &c., remarks that this 'Native Wood-Pheasant,' or 'Lyre Bird' of the colonists; the 'Béleck-Béleck' and 'Balangara' of the aboriginal tribes, is abundant about the mountain-ranges in all parts of the colony. The tail feathers are detached entire from the bird, and are sold in the shops at Sydney in pairs. Mr. Bennett observes that the price was formerly low; but now that the bird, from continued destruction, has become rare, their tails fetch from twenty to thirty shillings the pair. About the ranges however of the Tumat country, where they have been seldom destroyed, they are more frequently seen.

The same author states that it has its young in December, the season when all the wild animals in the colony are produced, and can be then procured with facility. 'It is,' says Mr. Bennett in continuation, 'a bird of heavy flight but swift of foot. On catching a glimpse of the sportsman it runs with rapidity, aided by the wings in getting over logs of wood, rocks, or any obstruction to its progress; it seldom flies into trees, except to roost, and then rises only from branch to branch: they build in old hollow trunks of trees which are lying upon the ground, or in the holes of rocks; the nest is formed merely of dried grass or dried leaves scraped together; the female lays from twelve to sixteen eggs of a white colour, with a few scattered blue spots; the young are difficult to catch, as they run with rapidity, concealing themselves among the rocks and bushes. The Lyre Pheasant, on descending from high trees, on which it perches, has been seen to fly some distance; it is more often observed during the early hours of the morning, and in the evenings, than during the heat of the day. Like all the gallinaceous tribe, it scratches about the ground and roots of trees, to pick up seeds, insects, &c. The aborigines decorate their greasy locks, in addition to the emu feathers, with the splendid tail feathers of this bird, when they can procure them.'

Mr. Bennett laments the rapid disappearance of the races of animals found in a new country, and which are pursued, whether useful or dangerous, even to extermination. He states that in the settled parts of the colony, the harmless kangaroos and emus are rarely seen, when they might easily be domesticated about the habitations. 'The same remark,' he adds, 'applies to the Lyre Pheasant. Why are they not domesticated, before, by extermination, they are lost to us for ever?'

We trust that this may meet the eye of some spirited individual who will *not* suffer the loss to take place, but bestir himself to import these magnificent birds. That they would live in this country, as well as the Emus and Kangaroos, with ordinary care, there can be little doubt; and they would form a striking addition to our aviaries,—perhaps even to our homesteads.

MÆOTIS, PALUS. [AZOFF, SEA OF.]

MÆRA, Dr. Leach's name for a genus of Amphipodous crustaceans.

Example, *Mæra grossimana*, Leach (*Cancer Gammarus grossimanus*, Montagu). 'Linn. Trans.,' ix., tab. 4, fig. 5. Very common on the English coasts, where it is found under stones and rocks at low water.

MAESTLIN, MICHAEL, a German astronomer, born about the year 1542, probably at Tübingen, in Wirtemberg, at the university of which place he held the appointment of professor of mathematics. While resident in Italy he became acquainted with Galilei, whose conversion from the doctrine of Ptolemy to that of Copernicus is partly attributed by some authorities to the arguments adduced by Maestlin in favour of the latter. Upon his return to Germany he became tutor to Kepler, to whom he behaved with marked liberality; for notwithstanding the great benefit which Kepler must have derived from his instruction, he declined accepting any pecuniary remuneration whatever; indeed Kepler does not appear to have been wanting in gratitude towards him, for both in his 'Mysterium Cosmographicum,' and in a letter prefixed to the 'Narrative of Rheticus,' he acknowledges the great encouragement he had invariably received from his tutor; and at a later period, when struggling with disappointment and poverty, he presented him with a handsome silver cup, bearing an appropriate inscription. Maestlin died at Tübingen, in 1590. His published works are: 1, 'De Stellâ nova.' 2, 'Ephemerides, according to the Prutenic Tables by Erasmus Reinold,' 1551. 3, 'Thesis de Eclipsibus.' 4, 'Observatio et Demonstratio Cometæ anni 1577 et 1578,' Tübing., 1578, 4to. 5, 'Consideratio et Observatio Cometæ,' 1580; Heidelb., 1581. 6, 'Alterum Examen Gregoriani Kalendarii,' Tübing., 1586, 4to. 7, 'Epitome Astronomiæ,' Tübing., 1597, 1610, &c.)

(Watt's *Bibliotheca Brit.*; Hutton's *Mathematical Dictionary*, &c.)

MAFFE'I, SCIPIO'NE, Marquis, born at Verona in 1675, of a noble family, was educated in the college of Parma, and showed an early aptitude for poetry and literature in general. When the war of the Spanish succession broke out, he entered as a volunteer the Bavarian service, in which his brother Alessandro Maffei held the rank of general. After passing some time in Germany he left the army for Italy with the view of devoting himself entirely to study. He wrote upon many and various subjects, and he generally wrote well. His principal works are—1, 'La Merope,' a tragedy, the first written in Italian which deserves the name; it was received with great applause, and went through seventy editions in the author's lifetime. 2, 'Verona Illustrata,' which is the principal work of Maffei, and full of antiquarian and historical learning. The first part contains a history of Verona from its foundation to the time of Charlemagne; the second is a literary history of Verona, with biographical notices of the native writers; the third is a stranger's guide to all the remarkable objects in Verona and its neighbourhood; in the fourth the author illustrates the Roman amphitheatre in that city, which is one of the best preserved remains of the kind. The whole work is written in a spirit of sound criticism, and exhibits the various features of the social, political, and intellectual state of that part of Italy during a long course of ages. 3, 'Della Scienza chiamata Cavalleresca libri trè,' dedicated to Pope Clement XI., in which he combats the absurdity of duelling. 4, Three treatises against the belief, then still prevalent, in magic: 'Arte Magica dileguata,' 1749; 'Arte Magica distrutta,' 1750; 'Arte Magica annichilata,' 1754. Maffei was charged by one Tartarotti with being almost an infidel because he did not believe in sorcery. 5, 'Trattato dei Teatri antichi e moderni,' in which he took up the defence of theatrical performers against the denunciations of

Father Concina, a Dominican, who attributed to them all the corruption of the age. Pope Benedict XIV., in a brief dated the 5th of October, 1750, addressed to Maffei, testified his full approbation of this defence, saying that 'theatres ought not to be suppressed, but that the performances ought to be as much as possible honest and decorous.'

Maffei had a controversy with the Jansenists on account of something which he wrote concerning the bull Unigenitus [JANSENISTS], and also because he maintained, against two priests of Verona named Ballerini, that it was lawful to receive a moderate interest on a loan of money, 'Impiego del Danaro.' The Jansenist party, which was powerful in North Italy, prevailed on the Venetian senate to exile Maffei, who was then seventy years of age. But the senate soon perceived their error, and Maffei was honourably recalled after four months, and re-entered Verona in triumph.

Maffei, in union with Vallisnieri and Zeno, originated the first literary Journal which appeared in Italy, 'Giornale dei Letterati,' begun in 1710, and which was continued till 1730. After the discontinuance of that journal he wrote a sort of continuation of it under the name of 'Osservazioni Letterarie,' of which he published six volumes.

In 1733 Maffei visited France, where he collected the materials for his work, 'Galliae Antiquitates,' which he afterwards published. He was numbered among the members of the Academy of Inscriptions. From France he visited England, and was well received at the court of George II., especially by the Prince of Wales, who was very fond of Italian literature. He was made a member of the Royal Society, and the university of Oxford, which he also visited, conferred on him the degree of LL.D. He travelled through Holland and Germany, and returned to Italy after an absence of four years.

Maffei died at Verona in the year 1755, being eighty years of age, with the well merited reputation of one of the best Italian scholars of the eighteenth century.

(Corniani, *Secoli della Letteratura Italiana*; J. Pindemonte, *Elogio di Scipione Maffei*.)

There is another but much older writer of the same name, Giovanni Maffei, who wrote a 'History of the East Indies,' in Latin, in 16 books, of which an Italian translation was published at Florence in 1589.

MAFRA is the name of a vast and magnificent pile of buildings, which contain a church, royal palace, and convent, situated in a bleak solitary country about 20 miles north-west of Lisbon, and about three miles from the sea-coast. It was founded by King John V. in the year 1717, in imitation of the Escurial of Spain. The plan of the edifice forms a quadrangle, measuring from east to west 760 feet, and from north to south 670 feet. In the centre of the west front is a sort of Ionic hexastyle portico, which leads to the church; and at each side is a pavilion, one for the accommodation of the royal family, the other for the patriarch of Lisbon and mitred canons. Another part of the building is the monastery, which contains 300 cells, a college, and a library, said to consist of between 40,000 and 50,000 volumes. The church is adorned with numerous columns of Carrara marble, and six very fine columns of red marble, besides large pannels and tables of perfectly black marble, highly polished. The number of apartments in the whole building is reckoned at 866, and the doors and windows at 5200. The whole of this building is vaulted and covered over with flags, forming a vast terrace. The gardens attached to the building are very extensive, and enclosed by a wall; they are well stored with a variety of exotics imported from Asia, Africa, and America. Father Joam de Prado published a full description of Mafra in 1751. The small town of Mafra has grown up round the monastery. (Kinsey, *Portugal Illustrated*; Murphy, *Travels in Portugal*.)

MAGADOXO, or **MUKDEESHA**, a town on the eastern shores of Africa, on the coast of Ajan. The town is situated about 2° 20′ N. lat. and 45° E. long., and is the only important place on the whole coast. The harbour is formed by a long coral reef, and the town is divided into two parts, Umarwyn, and Chamgany; the latter consists entirely of huts. Umarwyn contains nearly one hundred and fifty stone houses, built in the Spanish style. It carries on some commerce with Arabia. Its exports are ivory, gum, and a particular kind of cloth; it imports sugar, dates, salt-fish, iron, and slaves. Its sovereign is dependent on the Imam of Muscat in Arabia. (Owen's *Voyages to explore the Shores of Africa, Arabia, and Madagascar*.)

MAGALHAENS, FERNANDO, commonly but incorrectly called *Magellan*, was one of the most distinguished sea-officers of his time, and as a navigator and discoverer only inferior to Columbus. He was born about 1470, in some place in Alentejo, and entered the Portuguese navy at an early age. He was afterwards sent to the East Indies, where he served for five years under Alfonso Albuquerque, and distinguished himself at the conquest of the town of Malacca in 1511. He afterwards returned to Europe, either from discontent, because the recompense which he thought due to his services, and which he had demanded, had been refused, or through fear of punishment for having embezzled some money intrusted to him. Being desirous to distinguish himself by some great enterprise, and finding that the numerous voyages to America had made it evident that this continent extended to a great distance towards the south, and being at the same time aware that the Moluccas, or Spice Islands, discovered a few years before, were situated much farther to the west, he revived the idea of Columbus of sailing to Asia by a westerly course. According to some authorities he proposed the enterprise to King Emanuel, who rejected it; but others assert that he made the proposal in the first instance to the court of Spain, where it was favourably received by Cardinal Ximenes, the regent, and afterwards approved by the emperor Charles V. A squadron of five vessels, with 236 men on board, was fitted out for that purpose, and Magalhaens left S. Lucar de Barameda on the 20th September, 1519. His object being to discover a strait or open sea, which would take him to the Moluccas, he directed his course with great judgment to the southern shores of Brazil, and entered the La Plata river, but he was soon convinced that it was not a strait. He then sailed southward, along the eastern coast of America, and was obliged to pass the winter in the harbour of S. Julian (near 50° S. lat.), where a conspiracy was formed against him. In detecting and putting down this conspiracy he showed great sagacity, prudence, and resolution. He discovered and entered the strait, which bears his name, about the end of October, 1520, and reached its western extremity on the 27th of Nov., when he entered the Pacific Ocean. He navigated the Pacific for 3 months and 20 days without finding an island, but during this course he enjoyed continuous fair weather, with such favourable winds, that he bestowed on this ocean the name of Pacific, which it still bears. The length of the voyage however reduced the crew to the greatest distress for want of food, and they began to suffer also from the scurvy. So great were their hardships, that Pigafetta, who wrote an account of this voyage, is firmly persuaded that an expedition round the world would never be undertaken again; and indeed more than fifty years elapsed between the voyage of Magalhaens and that of Drake (1577). On the 6th of March, 1521, Magalhaens arrived at a group of islands, which he called Los Ladrones, from the inclination to theft which the inhabitants displayed. After having refreshed his crew, he continued his course westward, and discovered the extensive group of the Philippines, which he called the archipelago of S. Lazaro. He induced a chieftain of the island of Zebu to acknowledge the sovereignty of the king of Spain, promising to assist him in subduing his enemies. With this view he undertook an expedition against the chieftain of the small island of Matan, but he was courageously resisted by the inhabitants, and killed in the contest. The command of his vessels devolved on Juan Sebastian del Cano, who conducted them to the Moluccas, and thence to Spain.

MAGALHAENS, STRAITS OF, commonly called the *Straits of Magellan*, is the most extensive known strait on the surface of the globe. Its length in a straight line is above 200 miles; but if the three great bends are taken into the account, it is rather more than 300 miles. It divides the continent of South America from the South American Archipelago, commonly called Tierra del Fuego. The eastern entrance is formed by Cape de las Virgines on the continent and by Cape del Espiritu Santo, or Queen Catherine's Foreland, which is on King Charles's Southland, the largest of the islands composing Tierra del Fuego. At its western entrance are Cape Pillar on the south, on the island of South Desolation, and Cape Victory on the north, on a small island belonging to Queen Adelaide's Archipelago. The most northern bend of the Strait approaches 53° 10′ S. lat., and the most southern inlet, called Admiralty Sound, 55° S. latitude. The eastern extremity of the strait is situated in about 68° 20′ W. long., and the western in about 74° 40′.

This strait may be considered as divided into three parts. The eastern part extends from Cape de las Virgines to Cape Negro, and its direction as far as the first Narrow is nearly west, but afterwards to the south of west. In two places the strait contracts to a width of five or six miles, forming the two Narrows, of which the eastern is called De la Esperanza, and the second that of S. Simon. It is extremely difficult and dangerous to pass through these Narrows from east to west, as western winds prevail in them nearly all the year round, and the western currents, which set through them, sometimes acquire such strength as to run more than seven miles an hour, a rate which approaches the rapidity of a mountain-torrent. The eastern part of the strait is not encumbered with islands and cliffs, except at its western extremity near Cape Negro, where there occurs the island of Isabella and some smaller ones, as well as some shoals. The country on both sides of this part of the strait is rather level, except that at some distance from the shore a range of hills rises on each side to a moderate height, but with rather a precipitous ascent. No trees grow in this country; the bushes are few in number and stunted, and the grass coarse though abundant.

The central portion of the strait, from Cape Negro to Cape Froward, lies north and south, and is the widest part, extending in two large inlets, called the Useless Bay and Admiralty Sound, deep into King Charles's Southland. This part of the strait is the easiest to navigate, being free from islands and cliffs, except the large island of Dawson. The country on both sides rises into high mountains, especially in the neighbourhood of Cape Froward and on the opposite coast of King Charles's Southland. Some of the peaks are above the snow-line, which here occurs at about 3500 feet above the sea-level. Mount Sarmiento on Tierra del Fuego attains the height of 6000 feet. Between the mountains there are valleys of some extent, which, as well as the lower part of the mountains themselves, are covered with a heavy growth of timber-trees.

The western part of the strait extends from Cape Froward to Cape Pillar, in a direction nearly south-east and north-west. This part is very difficult to navigate on account of its narrowness, the width varying between 5 and 25 miles, and also by reason of the numberless cliffs and islets, with which the shores, especially on the north side, are lined. To these disadvantages must be added the north-western gales, which sweep with incredible force along the channel of the strait. The mountains on each side are not so high as along the central portion, and rarely attain the snow-line; but their huge masses approach so close to the shores that in many places it is difficult to find as much level ground as is required to place a boat upon. Land-locked basins of moderate extent however occur in several places, and afford safe harbours. The mountains, which consist mostly of granite and greenstone, are irregularly heaped together; most of them for two-thirds of their height are covered with trees of a stunted growth. Two large inland salt-water lakes are united with this portion of the strait. Nearly opposite the south-eastern extremity of the large island of South Desolation [Fuego] a channel opens eastward into the continent. This strait, called Jerome Channel, leads to Otway Water, a large inland sea 50 miles long, trending to the north-east, and separated from the eastern portion of the strait only by a narrow isthmus. From this lake another channel, called Fitzroy Channel, 12 miles long, leads in a north-west direction to another inland lake, called Skyring Water, which is about 34 miles long and 12 wide. The country bordering these lakes on the south and west is high, rocky, and mostly covered with trees; whilst that which encloses them on the east and north is a low, undulating, grassy plain, without trees.

The Strait of Magalhaens was discovered by Fernando Magalhaens in 1520. The Spanish government caused a settlement to be made on the northern shore, in the central part of the strait, by that skilful navigator Sarmiento, in 1583 or 1584. The settlement was called San Felipe, and was visited in 1587 by Cavendish, who found the settlers perishing with cold, hunger, and disease. From that time the place was called Port de Hambre or Port Famine, and was soon after abandoned.

The strait was formerly much navigated by vessels bound for the harbours on the western coast of America; but the navigation was always dangerous and tedious. Magalhaens had the good fortune to traverse it in less than thirty days, but his successors have frequently employed double or triple that time in passing through the strait from east to west. The difficulty is produced by the nearly continuous western gales, the great strength and irregularity of the currents, the numerous rocks and cliffs in the western part of the strait, and the great humidity of the climate, which engenders scurvy and other diseases. In sailing round Cape Horn only the first two difficulties are encountered, but the climate is much colder, and snow and sleet are common. The great improvements in navigation in modern times have deprived the voyage round the Cape of most of its difficulties, but they have not in the same degree lessened those which are encountered in traversing the strait. At present a vessel rarely enters the strait unless sent by some government for a special purpose.

(Cordova's *Voyage of Discovery to the Strait of Magellan;* Capt. Phillip Parker King's *Observations upon the Geography of the Southern Extremity of South America,* &c., in the *London Geogr. Journal,* vol. i.; *The Chart of the Strait of Magalhaens, surveyed by* Captain P. P. King, R.N., 1826, 1830.)

MAGAS. [Branchiopoda, vol. v., p. 313.]

MAGAZINE, a strong building, constructed generally of brick or stone within a fortified place, or in the neighbourhood of a military or naval station, in order to contain in security the gunpowder or other warlike stores which may be necessary for the defence of the place, or for the use of the troops who are to perform military duty in the province or district.

On account of the liability of gunpowder to become deteriorated by humidity and by variations in the state of the air, the buildings in which it is contained are constructed with every precaution necessary to ensure dryness, and, as nearly as possible, a uniformity of temperature within them. They are generally in places remote from other buildings; they are furnished with metallic conductors, in order to avert danger from lightning; and, for security against the attempts of ill-disposed persons, they are surrounded by a wall and ditch. When in situations where they may become the objects of hostile measures, they are made shell-proof.

A magazine within the walls of a fortress is usually formed on an esplanade; and, if small, it may be in the interior of some bastion remote from the front against which an attack of the enemy is likely to be directed. But it would be preferable that such buildings should be in some work beyond the main rampart of the place, that an accident may be attended with as little detriment as possible.

The powder required for the immediate service of the works on the front attacked is taken from the general magazine, and placed in what are called *expense magazines;* that is, in temporary bomb-proof buildings, or in casemates formed in the rampart along that front, from whence it is conveyed to the batteries. These casemates or *souterreins* should be as well ventilated as possible, by having doors and windows in the interior side of the rampart, and loop-holes or small perforations on the side next to the main ditch. They sometimes constitute the only bomb-proofs belonging to a fortress; and then they become of the utmost importance, serving as well for the abode of the troops, when not on duty, as for the preservation of the powder and stores. [Bomb-proof; Casemate.] In such situations however, as magazines, they are subject to some disadvantages from which isolated buildings are free; for besides the humidity, which the means they possess for ventilation are not sufficient entirely to remove, the blowing up of any one by an accident would evidently destroy the rampart, and expose the place to the risk of an immediate assault. And when the vault springs from the back of the wall which constitutes the exterior revêtment of the rampart on any face of the work, its lateral pressure would facilitate the formation of a breach by overturning the wall as soon as the latter became weakened by the fire from the enemy's battering artillery.

The dimensions of magazines are necessarily dependent on the quantity of powder which they may be required to contain. Vauban, in his 'Traité sur la *Défense des Places,*' speaking of such as are made in the ramparts of fortresses, recommends them to be from eight to twelve feet wide, with semicircular-headed vaults; and he proposes that the barrels of powder should be placed in them in two rows, with a passage from three to four feet wide along the middle. The great magazines which have been constructed in this country consist of several parallel vaults, separated from each other by brick partition-walls, in which are doorways for affording lateral communication. Each vault is about ninety feet long and nineteen feet wide internally, and it has a door at each extremity. The side walls are from eight to ten feet thick and are strengthened by buttresses built at intervals against them. The concave or interior surface of each vault, in a vertical and transverse section, is nearly of a parabolical figure, above the springing courses; and the exterior surface has the form of two inclined planes meeting in a longitudinal ridge-line above the middle of the vault. The thickness of the brickwork forming the vaulted roof is therefore various: at the crown it is seven or eight feet, and on the haunches about three feet, this being considered sufficient to resist the shock of falling shells. The vault, on the exterior of the inclined planes, is covered with flat tiles, and the gutter between every two roofs with sheet-lead or copper. The height interiorly, from the level of the floor to the crown of the vault, is nineteen feet; and the lines at which the vaulting springs from the side walls are at half that distance above the floor. The narrow vertical perforations which are made through the side and end walls, for the purpose of giving air to the interior, are cut so as to leave a solid block or traverse of the brickwork in the middle of the thickness of the wall; the line of the perforation branching laterally from its general direction, and passing along the two sides of the traverse. By this construction, while air is admitted, no object capable of doing mischief can be thrown in from the exterior of the building. The flooring-planks are, of course, laid on joists raised considerably above the ground. One vault of the dimensions above given, would contain 2250 barrels, or 225,000 lbs. of powder.

When the roof of a magazine is covered with earth to the height of several feet, for the purpose of securing it effectually against the effect of falling shells, the rain-water absorbed by the earth may at length penetrate through the brickwork to the interior of the building. In order to prevent this effect it has been proposed that the roof should be covered with common hollow tiles, having their concave surfaces upwards, and that, over these, boards should be laid to carry the earth. The absorbed water would thus drain off in the channels formed by the tiles, and be conveyed away by the gutters between the roofs.

MAGDALEN COLLEGE, Oxford, was founded in 1458, by William of Waynflete, successively head master of Winchester and Eton schools, and provost of Eton, bishop of Winchester, and at the same time lord high chancellor of England, for a president, 40 fellows, 30 scholars called Demies, a schoolmaster, an usher, four chaplains, an organist, eight clerks, and 16 choristers. Of the Fellows five must be of the diocese of Winchester; seven of the county of Lincoln; four of the county of Oxford; three of the county of Berks; four of the diocese of Norwich; two of the diocese of York or Durham, one of the county of York, but in both cases with preference to priests; two of the diocese of Chichester; two of the county of Gloucester; two of the county of Warwick; one of the county of Buckingham; one of the county of Kent; one of the county of Nottingham; one of the county of Essex; one of the county of Somerset; one of the city of London; one of the county of Northampton; one of the county of Wilts. The Demies may be elected from any of the above-mentioned dioceses or counties, with the exception of York and Durham. The Visitor is the Bishop of Winchester.

The patronage of this College consists of rectories and vicarages in different counties, with two perpetual curacies, thirty-seven in number.

The number of members upon the college books in 1838 was 191.

Among the eminent persons who received their education at this college are cardinals Wolsey and Pole, bishops Warner, Hough, and Horne, dean Colet, Linacre, Lily the grammarian, Fox, the martyrologist, Godwin, the Hebrew antiquary, Sir Thomas Roe, Hampden, Dr. Hammond, Dr. Heylin, Elisha Coles, Dr. Thomas Smith, Addison, Gibbon, and Dr. Chandler.

Magdalen College stands upon a plot of ground at the entrance of Oxford from London, bounded on its east side by the Cherwell. The buildings are extensive. In one corner of the entrance court stands the stone pulpit from which the University sermon on St. John the Baptist's day used to be preached. This court leads into a larger quadrangle, which contains the chapel, hall, and library. South of the chapel and on the south side of what is called the Chaplain's court stands the tower of the college, the beautiful proportions of which render it one of the chief ornaments of Oxford. The great quadrangle was begun by the founder in 1473, though not finished till after his death. The foundation of the tower was laid in 1492. Previous to the Reformation a mass of requiem for the soul of Henry VII. used to be performed upon the top of this tower every May-day early in the morning; this was afterwards commuted for a few pieces of music, which are still executed on that day by the choristers, for which the rectory of Slimbridge in Gloucestershire pays annually the sum of 10*l.* The foundations of what are called the 'New Buildings' of this college, on the north side of the great quadrangle, were laid in 1733.

The chapel of this college, which had been refitted and decorated in an incongruous manner in the time of Charles I., was restored to its former magnificence under the direction of Mr. Cottingham in 1833. The fine picture of 'Our Saviour bearing his Cross,' over the communion table, ranks among the best paintings in Oxford. It has been attributed by some to Guido, and by others to Ludovico Caracci, but it is now given to Morales. It was brought from Vigo in 1702.

(Gutch's *Coll. and Halls of Oxford*; Chalmers's *Hist. of the Univ. of Oxf.*, 8vo. Oxf., 1810; *Oxford Univ. Calendar*, 1839.)

MAGDALEN HALL, Oxford. The school, with the refectory and chambers erected by Bishop Waynflete for students previous to admission into his college, and adjoining its buildings, obtained the appellation of St. Mary Magdalen Hall as early as 1487, and was governed by one of the Fellows till 1602, when it became an independent hall. The President and Fellows of Magdalen College, being desirous of recovering this site, obtained, in 1816, an act of parliament which authorised them to prepare for the reception of this society Hertford College, which had lapsed to the crown, and the Principal and other members removed there on its completion in 1822.

This Hall is possessed of one benefice, the rectory of South Moreton in Berkshire. It has also several exhibitions and scholarships, open to competition, left by different founders.

The original foundation of Magdalen Hall boasted among the names of its more eminent members those of bishop Wilkins, Warner and Daniel the poets, Sir Harry Vane, Sir Julius Cæsar, Lord Clarendon, Sir Matthew Hale, Sydenham, Dr. Pocock, afterwards of Corpus College, Dr. Hickes, afterwards of Lincoln, Dr. Plot, Sir George Wheler, and Dr. Nichols, the commentator on the liturgy.

The buildings of the old Hall were destroyed by an accidental fire, Jan. 9th, 1820.

(Chalmers, *ut supr.*, vol. ii. 453; *Oxford Univ. Calendar*, 1839; *Gent. Mag.*, vol. xc., P. ii., p. 78.)

MAGDALEN COLLEGE, Cambridge, was built by Edward Stafford, duke of Buckingham, in the year 1519, under the name of Buckingham House, on the site of an antient hostel belonging to the abbeys of Ely, Ramsey, and Walden, in which some of the monks of those monasteries resided from time to time. At a much more remote date it is supposed by some to have been the original site of Barnwell Priory. The Duke of Buckingham not having completed the building at the time of his attainder, the college fell to the crown and was granted to Thomas, lord Audley, lord high chancellor of England, who in 1542 endowed it for a Master and four Fellows.

Beside the foundation fellowships left by lord Audley, this College has thirteen bye-fellowships; one of them is a travelling fellowship left by the Rev. Drue Drury, worth upwards of 200*l.* per annum, but tenable for only nine years, and appropriated to the county of Norfolk. The Master has the sole appointment to this fellowship, and the holder must be in holy orders or designed for such.

The mastership of this College is in the gift of the possessor of Audley End.

Beside the fellowships, there are 45 scholarships belonging to this College, founded by different benefactors, some of considerable, others of smaller value; four of them are appropriated to Shrewsbury school; two to natives of Shropshire; two to scholars from Wisbeach school; four to Leeds, Halifax, and Heversham schools; and one to King's College, London.

The foundation-estate of lord Audley consists of the impropriate parsonage of St. Catharine Cree Church, in London, and also a considerable part of the city antiently called Covent Garden Christ Church. The benefices in the gift of the College, exclusive of the vicarage of St. Catharine Cree in London, are, the rectory of Stanton St. Michael in Cambridgeshire, the rectories of Anderby and Comberworth united, and the perpetual curacy of Grainthorpe in Lincolnshire; the rectory of Ellingham in Norfolk (annexed to the mastership by act of parliament); the rectory of Aldrington in Sussex, and the vicarage of Steeple Ashton in Wilts. The Master has the sole patronage of Steeple Ashton.

Among the eminent persons who have been members of Magdalen College are lord keeper Bridgman, bishop Walton, editor of the Polyglot Bible, Dr. Howell, the historian, bishop Cumberland, and Dr. Daniel Waterland.

This College, which stands on the north side of the Cam, consists of two small courts. On the north side of the second is a stone building, the body of which is appropriated to the reception of the Pepysian Library. This library was bequeathed to the College by Samuel Pepys, Esq., Secretary of the Admiralty in the reigns of king Charles II. and king James II., and is one of the most interesting in the University. Its contents are matchless both in variety and condition. With a few exceptions in morocco and vellum, they are all in a uniform binding in calf, gilt. Beside numerous manuscripts, this library is remarkably rich in works from the presses of Caxton, Wynkyn de Worde, and other early English printers. It contains a curious collection of engraved English portraits, numerous topographical prints and drawings, and a very rare and extensive collection of early ballads. There is an enumeration of some of the most interesting works in this library in Hartshorne's *Book Rarities in the University of Cambridge*, 8vo., London, 1829, p. 217-269.

The number of members on the boards of this College, March 12, 1838, was 188.

(Lysons's *Cambridgeshire*, pp. 123, 124; *Cambridge University Calendar* for 1838.)

MAGDALE'NA, River. [GRANADA, NEW.]

MAGDEBURG, one of the three governments of the Prussian province of Saxony, is composed of the antient duchy of Magdeburg, the county of Barby, the bailliwick of Gommern (without the circle of the Saal), the Altemark (Old Mark), on the left bank of the Elbe, the bailliwick of Klötze, the principality of Halberstadt, with Derenburg, Quedlinburg, Wernigerode, and Schauen. Its area is 4410 square miles, and the population, according to the census of 1837, amounted to 598,981. The government is divided into fifteen circles. The country is one of the finest parts of the Prussian monarchy, consisting chiefly of a fertile and level tract; the hills in the south-west, which are offsets of the Harz, are low, and in other parts the surface is merely varied by gentle elevations. [SAXONY, PRUSSIAN PROVINCE OF.]

The duchy of Magdeburg is not to be confounded with the government of the same name; which contains only a part of the duchy, the other part being in the government of Merseburg.

MAGDEBURG, the capital not only of the government but of the province of Saxony, is situated on the left bank of the main arm of the Elbe, in 52° 8′ N. lat. and 11° 39′ E. long. It is a fortress of the first rank, and one of the most important bulwarks of the Prussian monarchy. The city consists of four parts and two separate suburbs:—1, The old town, or principal fortress along the Elbe, with eleven bastions and ten small ravelins between them, with various other works. They are everywhere strengthened by a double, and in some parts by a triple-covered way, and by mines. South of the old town lies—2, the Stern, a square casemated tenaille, built under Federick II. by General Wallrave, who died here in a prison erected by himself, where he was confined for treachery. Between the Stern and the old town there was formerly a suburb called Sudenburg, which was pulled down in 1811 by the French, who built on the site Fort Napoleon, now called Fort Scharnhorst. The long bridge, over the broadest arm of the Elbe, leads from the city to—3, the citadel, built in 1680, on an island, by king Frederick I. Over the two smaller arms of the Elbe, beyond it, there are drawbridges; and beyond lies —4, Friedrichstadt, or Thurmschanze (*i.e.* Tower Fort), which defends the entrance on the right bank of the Elbe, where the newly-built Frederick-William bridge, 1080 feet long, leads over the low ground on the bank of the river. The suburb of Neustadt, lying to the north, as being too near to the fortifications, was partly destroyed in 1806 by the Prussians, and entirely demolished in 1811 and 1812 by the French, together with the adjoining suburb of Sudenburg. It has been partly rebuilt since 1818.

Magdeburg, like most old continental towns, has in general narrow and crooked streets, but having been rebuilt since its destruction by Tilly in 1631, it is better constructed than many antient cities. Among the more remarkable buildings are—the townhall, built in 1691, the ducal palace, the provincial assembly-house, the artillery barracks, the government-house, and the theatre. The celebrated cathedral was completed in 1363, after having been 150 years building. It has two steeples 350 feet high, a lofty nave supported by twelve pillars, a high altar of jaspar, forty-five smaller altars, a pulpit of alabaster, and a font of one block of porphyry. There are twelve churches, one of which is Roman Catholic. There are two large squares, the old market-place, in which is the statue of the emperor Otho the Great, erected in 973, and the cathedral square, which is surrounded by handsome buildings and avenues of trees. The public establishments and charitable and scientific institutions are numerous and well conducted: and as the city, with a population of 50,000, is the capital of the province of Saxony, as well as of the government and circle, the residence of the chief president*, of a Protestant bishop, and the head-quarters of the fourth corps of the Prussian army, with several public libraries, collections of pictures, literary and other clubs, and all kinds of public amusements, such as theatres, balls, concerts, &c., it is accounted a very agreeable place of residence. It has also considerable manufactures, extensive breweries and distilleries, and a very active trade. Magdeburg is rich in historical recollections; the most celebrated and unfortunate event in its annals is its capture by storm on the 10th of May, 1631, by the Austrian general Tilly, when it was given to pillage for three days, and 30,000 of the inhabitants were put to the sword; the whole city, except the cathedral, one of the churches, and about 130 houses, was at the same time reduced to ashes.

(Rathmann, *Geschichte der Stadt Magdeburg*; Schiller *Thirty Years' War*; Hassel, Stein, &c.)

MAGELLAN. [MAGALHAENS.]

MAGELLANIC CLOUDS. [NEBULÆ.]

MAGGIO'RE, LAGO. [LAGO MAGGIORE.]

MAGI, the name of the priests among the Medes and Persians, whose religious doctrines and ceremonies are explained under ZOROASTER. The Magi formed one of the six tribes into which the Medes were originally divided (Herodot. i. 101); but on the downfall of the Median empire they continued to retain at the court of their conquerors a great degree of power and authority. It would appear however that they did not witness with indifference the sovereignty pass from the Medes to the Persians; and it was probably owing to the intrigues of the whole order that a conspiracy was formed to deprive Cambyses of the throne by representing one of their order as Smerdis, the son of Cyrus, who had been previously put to death by his brother. Herodotus, who has given the history of this conspiracy at length, evidently regarded it as a plot on the part of the Magi to restore the sovereignty to the Medes, since he represents Cambyses on his death-bed as conjuring the Persians to prevent the Medes from obtaining the supremacy again (Herodot., iii. 65); and the Persians themselves must have looked upon it in the same light, since after the discovery of the conspiracy, and the murder of the pretended Smerdis by Darius Hystaspes and his companions, a general massacre of the Magi ensued; the memory of which event was annually preserved by a festival, called the 'Slaughter of the Magi' (Μαγοφόνια), in which none of the Magi were allowed to appear in public. (Herodot., iii. 79; Ctesias, *Pers.*, c. 15.) This event does not appear to have much impaired their influence and authority, for they are represented by Herodotus, in his description of the [illegible] religion, as the only recognised ministers of [illegible] religion (i. 132).

The learning of the Magi was con[illegible] and enchantment, in which they [illegible] their name was applied to all [illegible] enchanters. Thus the Sept[illegible]

---

* The Prussian governments, or [illegible] of which is a chief president, [illegible]

מְכַשְּׁפִים, 'enchanters,' by the word Magus, μάγος (*Dan.*, i. 20; ii. 2, 27; compare *Acts* xiii. 6, 8). The word was also applied in Scripture to any men celebrated for wisdom; whence the wise men of the East who came to see Christ are called simply Magi (*Matt.*, ii. 1, 7, 16.)

It would appear from a passage in *Jeremiah* (xxxix. 3), that the Babylonian priests were also called Magi, if at least the interpretation of *Rab-Mag* (רַב מָג, '*chief of the Magi*') be correct. (Gesenius, *Hebrew Lexicon*, under מָג.)

The etymology of this word is doubtful. In Persian the name for priest is *mugh*; and it is not improbable, as Gesenius has conjectured, that the word may be connected with the root meaning *great*, which we have in the Greek μέγ-α, the Latin *mag-is* and *mag-nus*, the Persian *mih*, and the Sanskrit *mah-at*. It is a curious fact that the Hindu grammarians derive *mah-at* from a verb *mah*, signifying 'to worship.' (Wilson's *Sanskrit Dictionary*, under *mah-at*.)

MAGIC SQUARE. This term is applied to a set of numbers arranged in a square in such a manner that the vertical, horizontal, and diagonal columns shall give the same sums. Such arrangements were known very early to the Hindus, Egyptians, and Chinese, among whom, as also among the Europeans of the middle ages, a belief existed that such squares had astrological and divinatory qualities. Emanuel Moscopulus,* of Constantinople, wrote on them in Greek in the middle of the fifteenth century. Others who have written on the subject are [illegible], Frenicle, Bachet, La Hire, Sauveur, &c. (See Montucla's *History*, vol. i., p. 350; *Encyclopédie Méth.*, article 'Quarrés magiques;' Hutton's *Dictionary*; and the *Mathematical Recreations* of the same author.)

Though the question of magic squares is in itself of no use, yet it belongs to a class of problems which call into action a beneficial species of investigation. Without laying down any rules for their construction, we shall content ourselves with destroying their magic quality, and showing that the nonexistence of such squares would be much more surprising than their existence.

Take any set of numbers in arithmetical progression, and such that their number shall be a square number; say the first sixteen numbers—

1	2	3	4	5	6	7	8
16	15	14	13	12	11	10	9

Every one of those in the first half, with its corresponding number in the second half, makes up 17. Write the numbers in the following manner—

1	2	3	4
5	6	7	8
9	10	11	12
13	14	15	16

Take four of these in such a manner as to take one out of each row, and one out of each column, and it will be found, and may easily be proved, that the sum of numbers in every such set must consist of two pairs of corresponding numbers, so that their sum must be twice 17, or 34. The different ways in which this can be done are in number 4 × 3 × 2 × 1, or 24, as follows—

1	6	11	16	5	2	11	16	9	2	7	16	13	2	7	12
1	6	15	12	5	2	15	12	9	2	15	8	13	2	11	8
1	10	7	16	5	10	3	16	9	6	3	16	13	6	3	12
1	10	15	8	5	10	15	4	9	6	15	4	13	6	11	4
1	14	7	12	5	14	3	12	9	14	7	4	13	10	7	4
1	14	11	8	5	14	11	4	9	14	3	8	13	10	3	8

Out of these subdivisions a set may be taken from each, so that no number shall be repeated, in 24 different ways, as in the following sample, which shows the four ways that begin with 1, 6, 11, 16.—

1	6	11	16	1	6	11	16	1	6	11	16	1	6	11	16
5	2	15	12	5	2	15	12	5	10	15	4	5	14	3	12
9	14	7	4	9	14	3	8	9	14	3	8	9	2	15	8
13	10	3	8	13	10	7	4	13	2	7	12	13	10	7	4

Now in each of these 24 squares, every horizontal row can be written in 24 orders (COMBINATIONS), and in putting the different orders together, each square admits of 24 × 24 × 24 × 24, or 331,776 arrangements, without altering the horizontal rows, but only the order of the figures in each row. But the order of the horizontal rows can be varied 24 ways in each square, and there are 24 squares; so that we have 331,776 × 24 × 24, or 191,102,976 squares, no one of which repeats any number more than once, and in every one of which the sum of any horizontal row is 34, made by two pairs of numbers which give 17 each. But the number of ways of forming 34 out of four of the first sixteen numbers is not yet exhausted; for, taking any one set, say

1	16	11	6

in which 1 and 6 correspond to 16 and 11, we may write 2 and 5, or 3 and 4, for 1 and 6, so that we have not included in the preceding list

2	16	11	5
3	16	11	4

with all their variations of order; and similar ones for all the rest of the list. It would be almost impossible to doubt that in many of this enormous number of squares, the vertical columns will sometimes be sums of these very sets; and it would be something short of magic if some should also have diagonal columns which fulfil the same condition. In fact, Frenicle has shown 880 methods of making these squares magical, a few of which are as follows (*Divers Ouvrages*, &c., Paris, 1693):—

1	16	11	6	4	11	14	5	13	4	5	12	16	3	10	5
13	4	7	10	6	13	12	3	16	6	11	1	8	2	13	11
8	9	14	3	9	2	7	16	3	9	8	14	9	15	4	6
12	5	2	15	15	8	1	10	2	15	10	7	1	14	7	12
8	12	5	9	8	10	3	13	8	12	5	9	10	11	5	8
11	1	16	6	15	1	12	6	10	1	16	7	15	2	16	1
13	7	10	4	9	7	14	4	13	6	11	4	6	7	9	12
2	14	3	15	2	16	5	11	3	15	2	14	3	14	4	13

In Frenicle's list of 880, only those squares are included which are essentially different; thus the following four, which may be made by turning the last square into different positions, count only as one.

10	11	5	8	8	1	12	13	13	4	14	3	3	6	15	10
15	2	16	1	5	16	9	4	12	9	7	6	14	7	2	11
6	7	9	12	11	2	7	14	1	16	2	15	4	9	16	5
3	14	4	13	10	15	6	3	8	5	11	10	13	12	1	8

The methods which have been given for the formation of magic squares are divided into different rules, according as the number in each side is odd, evenly even, or oddly even. A general method which shall apply to all cases is yet wanting. For a full account of these rules see Hutton's *Mathematical Recreations*.

MAGI'LUS, De Montfort's name for a genus of testaceous mollusks, the form of whose shell varies very much according to its different stages of growth and the circumstances in which it is placed.

The genus was placed by Lamarck among his *Annelids*, in the family *Serpulacea*, containing the genera *Spirorbis*, *Serpula*, *Vermilia*, *Galeolaria*, besides that under consideration.

M. de Blainville arranged it among the mollusks (family *Cricostomata*), between *Siliquaria* and *Valvata*, observing at the same time that Guettard clearly saw the relation of the form to *Vermetus*.

Cuvier, in his last edition of the 'Règne Animal,' gives it a position between *Vermetus* and *Siliquaria*, in his seventh order of Gastropoda (*Tubulibranchiata*).

M. Rang remarks that when he was seeking the animal in India he was struck, like M. de Blainville, with the analogy which the genus presents not only to *Vermetus*, but also to many other genera of *Pectinibranchiata*. This analogy, M. Rang further observes, is especially remarkable when a young individual whose shell has not yet become tubular is examined.

Description.—Animal.—M. Rang states that he saw some fragments of the animal, and that it is certainly a Gastropod. In his description however he notes the animal as unknown. Dr. Rüppell states that it is furnished with an operculum.

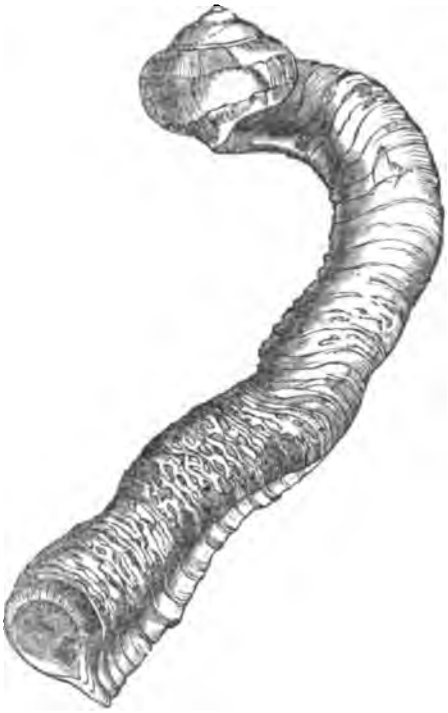
Shell.—Young:—Fragile, with an epidermis, pyriform, ventricose, with a short spire of from three to four turns; aperture longer than it is wide, oblong, without any notch anteriorly, where the lip nevertheless forms an angle. Dr. Rüppell thinks that M. Rang, when he wrote the above description, had before him the young of *Leptoconchus*. Adult:—The last whorl abandoning altogether the spiral form to produce an elongated tube, which is irregularly sinuous, or irregularly contorted, conical, compressed laterally, especially on the side of the base of the shell, carinated beneath, and free; aperture elliptical.

---

* [illegible] Emanuel Moschopulus the elder, a [illegible] of the end of the [illegible] century.

Shell of Magilus (young).

When in this state the shell presents all the characters of a regularly spiral univalve. The animal establishes itself in the excavations of Madrepores (*Astrææ*, &c.), and as the coral increases around it the *Magilus* is obliged, in order to have its aperture on a level with the surrounding surface, or near it, to construct a tube, which is more or less eccentric according to circumstances, the growth of the coral determining the length of the tube. As this tube goes on increasing, the animal abandons the spiral for the tubular part of the shell, and in this operation it leaves behind no *septa*, or partitions, but secretes a compact calcareous matter which reaches to the very summit of the spiral part, and is deposited from time to time as the tube is lengthened; so that in an old specimen the posterior part of the shell presents a solid and almost crystalline mass. Indeed the fracture of this mass is radiated and saccharoid. One species only, *Magilus antiquus*, is known. The colour is white, more or less pure.



Shell of Magilus (old).

The reader will find the differences between *Magilus* and *Leptoconchus*, as stated by Dr. Rüppell, in the article on the last-named genus.

MAGINDANAO. [PHILIPPINE ISLANDS.]

MAGLIABE'CCHI, ANTO'NIO, born at Florence in 1633, early showed a great aptitude for philological and historical studies; he was an indefatigable reader, and had a prodigious memory. He employed his scanty savings in buying books, and gradually collected a vast library, which since his death has become the property of the city of Florence, and is open to the public, and known by the name of Magliabecchiana. Magliabecchi, in consequence of his immense erudition, was considered as an oracle, and was consulted by scholars from every part of Europe. Several princes showed by compliments and gifts their regard for him. His own sovereigns, the grand-dukes Medici, appointed him their librarian. Magliabecchi left no work of his own. Some of his letters have been published in various collections: 'Lettere di Uomini Illustri,' Macerata, 1782; 'Lettere di Uomini Dotti,' Venezia, 1807; 'Prose Fiorentine,' &c. Unfortunately Magliabecchi was very vain, irritable, and abusive, and his temper involved him in personal quarrels with several of his contemporaries. He died at Florence, in 1714, at eighty one years of age.

MAGNA CHARTA. The terms of the compact between the feudal chief and his dependants underwent frequent changes in the middle ages, the consequence for the most part of resistance made by the tenants, and struggles to regain liberties which had been originally surrendered or taken from them by the force and power of the chief. When a material alteration was made in the terms of the compact, a record was made of it in writing. These records are called charters, in the restricted use of a term which is popularly applied to almost every species of early diplomas. The tenants of the various honours, or great tenancies in capite, are seldom without one or more charters which have been granted to them by their lords, by which exemptions or privileges are given, base services are commuted for payments in money, and the mode is settled in which justice shall be administered among them. And even in some of the inferior manors there are charters of a similar kind by which certain liberties are guaranteed by the lord to his tenants. These charters run in the form of letters, '*Omnibus*,' &c. from the person granting; they set forth the thing granted, and end with the names of persons who were present when the lord's seal was affixed, often ten, twelve, or more, with the date of place and time of the grant.

Such a charter is that called the Magna Charta granted by King John, but acting in his twofold character of the lord of a body of feudatories, and the sovereign of the realm. This charter is often regarded as the constitutional basis of English liberties, but in many of its provisions it seems to have been only a declaration of rights which had been enjoyed in England before the Conquest, and which are said to have been granted by King Henry I. on his accession. However, if it did not properly found the liberties which the English nation enjoys, or if it were not the original of those privileges and franchises which the barons (or the chief tenants of the crown, for the names are here equivalent), ecclesiastical persons, citizens, burgesses, and merchants enjoy, it recalled into existence, it defined, it settled them, it formed in its written state a document to which appeal might be made, under whose protection any person who had any interest in it might find shelter, and which served, as if it were a portion of the common law of the land, to guide the judges to the decisions they pronounced in all questions between the king and any portion of the people.

Beside the great charter there was granted at the same time a charter relating to the forests only. There were very extensive tracts of land in England which were actually forests, uncultivated, and reserved for the pleasure of the king; and there were purlieus to these forests, all of which were subject to a peculiar system of law, many parts which were felt to be oppressive, and from some of which this charter exempted the people.

The independence and rights of the church were also secured by the great charter.

Magna Charta has been printed in a great variety of forms: there are fac-similes of a copy of it which was made at the time, and still exists in the British Museum, and of another preserved at Lincoln, and translations of it into the English language. It is thus so easily accessible, that it will not be expected that we shall give a copy of it, or even a complete abstract of its multifarious provisions, some of which are completely obsolete, and the terms obscure. Instead of this we shall give the satisfactory abridgement of Blackstone, in his 'Commentaries,' who has besides an express treatise on this charter.

'The great charter,' says he, 'confirmed many liberties of the church, and redressed many grievances incident to feodal tenures, of no small moment at the time; though now, unless considered attentively and with this retrospect, they seem but of trifling concern. But besides these feodal provisions, care was also taken therein to protect the subject against other oppressions, then frequently arising from unreasonable amercements, from illegal distresses or other process for debts or services due to the crown, and from the tyrannical abuse of the prerogative of purveyance and pre-emption. It fixed the forfeiture of lands for felony in the same manner as it still remains; prohibited for the future the grants of exclusive fisheries, and the erection of new bridges so as to oppress the neighbourhood. With respect to private rights: it established the testamentary power of the subject over part of his personal estate, the rest being distributed among his wife and children; it laid down the law of dower as it hath continued ever since; and prohibited the appeals of women, unless for the death of their husbands. In matters of public policy and national concern, it enjoined an uniformity of weights and measures; gave new encouragements to commerce by the protection of merchant-strangers, and forbad the alienation of lands in mortmain. With regard to the administration of justice: besides prohibiting all denials or delays of it, it fixed the Court of Common Pleas at Westminster, that the suitors might no longer be harassed with following the king's person in all his progresses; and at the same time brought the trial of issues home to the very doors of the freeholders, by directing assizes to be taken in the proper counties, and establishing annual circuits; it also corrected some abuses then incident to the trials by wager of law and of battle; directed the regular awarding of inquests for life or member; prohibited the king's inferior ministers from holding pleas of the crown, or trying any criminal charge, whereby many forfeitures might otherwise have unjustly accrued to the exchequer, and regulated the time and place of holding the inferior tribunals of justice, the county court, sheriff's tourn, and court-leet. It confirmed and established the liberties of the city of London, and all other cities, boroughs, towns, and ports of the kingdom. And lastly (which alone would have merited the title that it bears of the *great* charter), it protected every individual of the nation in the free enjoyment of his life, his liberty, and his property, unless declared to be forfeited by the judgment of his peers or the law of the land.'

Such a concession from the king was not gained without a violent struggle; in fact he was compelled to yield it by an armed force, consisting of a very large portion of the baronage, which he was far too feeble to resist with effect. The names of the chiefs are preserved by the chroniclers of the time, and in the charter itself; and whenever recited, they call up to this day a mingled feeling of respect and gratitude, the respect and gratitude which men pay to those who have obtained for them the extension of political privileges, though it may appear that those privileges were nothing more than rights of which they had been deprived, and to which therefore they may be said to have been justly entitled. They appear the patriots of a rude age, and the mists of distance and antiquity obscure to us the selfishness and the other evils (if such existed) which were manifested in the contest. The first name is that of Robert Fitz Walter, who belonged to the great family of Clare. The title given to him as head of the host was Marshal of the Army of God and of the Holy Church. Next to him come Eustace de Vesci, Richard de Percy, Robert de Roos, Peter de Brus, Nicholas de Stutevile, Saier de Quenci, earl of Winchester, the earls of Clare, Essex, and Norfolk, William de Mowbray, Robert de Vere, Fulk FitzWarine, William de Montacute, William de Beauchamp, and many others of families long after famous in English history, the progenitors of the antient baronial houses of England.

The charter was signed, or rather sealed, not in any house, but in the open field, at a place called Runnymede, between Windsor and Staines; but it was not merely by an accidental meeting of two armies at that place that this act was done there, for it appears by Matthew of Westminster that Runnymede was a place where treaties concerning the peace of the kingdom had been often made. All was done with great solemnity. The memorable day was June 5, 1215.

What was unwillingly granted, it could scarcely be expected would be religiously observed. John himself would gladly have infringed or broken it, as would his son King Henry III., but the barons were watchful of their own privileges, those of the church, the cities, the boroughs, and of the people at large; and King Henry was led to make one or more solemn ratifications of the charter. To keep the rights thus guaranteed fully in the eyes of the people a copy was sent to every cathedral church, and read publicly twice a year.

See the work of Sir William Blackstone, entitled 'The great Charter and Charter of the Forest, with other authentic Instruments; to which is prefixed an Introductory Discourse concerning the History of the Charters,' Oxford, 1759, 4to. The late Board of Commissioners on the public Records caused to be engraved and published an exact fac-simile of the charter, from a copy preserved in the archives of the cathedral church of Lincoln, with other of the greater charters. In the first volume of their work, entitled 'The Statutes of the Realm,' these charters are all printed, with English translations of them.

MAGNA GRÆ'CIA, or MAJOR GRÆCIA (Liv., xxxi. 7; Justin, xx. 2), was used to designate the south of Italy, in consequence of the numerous and flourishing colonies which were founded by the Greeks in that part of the country. There is some difficulty in determining how far north this name extended; but it does not appear to have been applied to the country beyond Cumæ and Neapolis; and some geographers have thought, though without sufficient reasons, that it was confined to the colonies on the Gulf of Tarentum. Pliny apparently considers Magna Græcia to begin at the Locri Epizephyrii (*N. H.*, iii. 15); but Strabo even includes the Grecian towns of Sicily under this name (vi. 175, *Casaubon*, 1587).

The time in which the name of Magna Græcia was first applied to the south of Italy is uncertain. It does not occur, as far as we are aware, in the early Greek writers, Herodotus, Thucydides, &c.; but it is used by Polybius (ii. 126, B, *Casaubon*) and succeeding Greek and Roman writers.

Taking the name in the widest signification which is given to it by Strabo, Magna Græcia may be justly considered as an appropriate name; since it contained many cities far superior in size and population to any in Greece itself. The most important of these places were, Tarentum, founded by the Lacedæmonians; Sybaris, Croton, and Metapontum, by the Achæans; Locri Epizephyrii, by the Locrians; and Rhegium, by the Chalcidians—all in Italy; and in Sicily—Syracuse, founded by the Corinthians; Gela, by the Cretans and Rhodians; and Agrigentum, by the inhabitants of Gela.

MAGNE'NTIUS, commander of the Roman army in Gaul, revolted against Constans, son of Constantine the Great, and emperor of the West, and caused him to be killed near the Pyrenees, A.D. 350. Constantius, the brother of Constans, and emperor of the East, marched against Magnentius, and a battle was fought between them on the banks of the Drave, A.D. 351. Magnentius, being defeated, fled to Italy, from whence he escaped into Gaul, where Constantius followed him and defeated him again, A.D. 353. Magnentius, finding himself forsaken by his troops, killed himself; and his brother Decentius, whom he had made Cæsar, followed his example. Constantius thus became sole master of the whole empire.

British Museum. Actual Size. Copper.

MAGNE'SIA. [ANATOLIA.]

MAGNESIA. [MAGNESIUM.]

MAGNESIA, MEDICAL PROPERTIES OF. Oxyde of magnesium, termed also, from the mode of procuring it, calcined magnesia, or magnesia usta, is an alkaline earth possessing the usual qualities of alkalies in their habitudes with acids, and likewise the peculiar property of exciting generally purgative action of the intestines. This last-mentioned power gives it a distinctive character among alkaline remedies, as it can be employed not merely to counteract acidity, but also to remove the exciting cause when that consists in the presence of crude or undigested acid-yielding materials in the stomach. Its action as a purgative seems mainly to depend upon its meeting with acids in the stomach, and so forming soluble salts. When these are not present the magnesia remains undissolved, and if used repeatedly may accumulate in the intestines, and, becoming agglutimated by the mucous secretions, give rise to much uneasiness. [ANTACIDS.] When however acidity exists, either along with constipation or diarrhœa, more particularly in children, from the milk disagreeing, or from a diet unsuited to their delicate organs of digestion being forced upon them, magnesia is a very proper medicine, especially as it appears to possess a specific power of diminishing gastro-intestinal irritation. (Hufeland, quoted in Pereira's *Materia Medica.*) It is generally expedient to add rhubarb to it, and combine it with some carminative. In such a state of combination it is peculiarly useful in what is termed diarrhœa crapulosa, arising from too great a mixture or too large a quantity of food.

Where it is determined to use magnesia, and sufficient acid does not exist in the stomach to ensure the formation of a soluble salt, a little lemon-juice may be added to it. The subcarbonate of magnesia has nearly the same action as the calcined magnesia, but when it meets with acids in the stomach effervescence takes place, accompanied with a disengagement of carbonic acid gas, which in some cases is inconvenient, in other instances extremely beneficial. In some almost uncontrollable irritations of the stomach, where food and medicines are alike rejected, subcarbonate of magnesia will be retained, and, by allaying the irritability, allow other remedies to be subsequently employed. Both the subcarbonate and the calcined magnesia are much used to correct heartburn, and to check the lithic acid diathesis; but their employment requires much judgment and attention. [ANTACIDS; ANTALKALIES.]

Sulphate of Magnesia, or Epsom salts, in the ordinary form, as met with in the shops, are small acicular crystals. This renders them liable to be confounded with those of oxalic acid; to avoid which the sulphate may be dissolved, and by recrystallization they are obtained in large four-sided prisms, or four-sided pyramids. The taste of sulphate of magnesia is bitter and very unpleasant; but this is very much lessened by large dilution in water, which at the same time increases the purgative action of the salt, or by adding magnesia, or by giving it in compound infusion of roses and adding a few drops of dilute sulphuric acid, which augments the refrigerating property of the medicine. The addition of a little common salt to a solution of sulphate of magnesia increases its cathartic powers.

No saline medicine is so extensively employed as the sulphate of magnesia as a purgative; it is more rarely used as a diuretic or diaphoretic. Its action as a purgative is in general mild and certain, causing a considerable evacuation of the serous secretions of the intestines, and so producing a cooling or lowering effect. At the commencement of most inflammatory complaints and of fevers its employment is most beneficial. Its utility is often much increased by adding to the solution a very minute portion of tartarized antimony, so as to form the emetico-cathartic solution, which was very serviceable in the fevers of India, and in those of the summer and autumn of European countries.

Small doses of sulphate of magnesia in bitter infusions are valuable in the treatment of dyspepsia accompanied with constipation. Many of the saline mineral waters resorted to for the cure of indigestion are chiefly indebted to the sulphate of magnesia for their purgative properties.

Sulphate of magnesia is a convenient antidote in cases of poisoning by the salts of lead or baryta.

Magnesian limestone is sometimes employed for building, and is a very durable stone: it is however one of the most deleterious stones for masons to hew, as the gritty particles very speedily occasion disorders of the lungs, followed by early death. The mouth and nostrils of the workmen should therefore always be defended by wearing a gauze mask.

MAGNESIAN LIMESTONE, in English geology, a 'formation' of the pœcilitic or new red-sandstone system; also the name of a group of limestone beds, which constitute the principal part of that formation, and generally contain a notable quantity of magnesia in their composition. Details regarding the formation will be more usefully combined in the account of the system of which it constitutes the base. We shall here confine ourselves to a notice of the limestone. This rock is seen to greatest perfection in England between the rivers Tyne and Tees, between the rivers Wharf and Dun, and between this last river and Nottingham. We mention these parts of the great line of magnesian limestone in the north of England for the purpose of pointing out some interesting differences in the composition and other characters of the rock. It is in the middle part of the course here indicated, from north to south, that the stratification of the rock is most developed. Between the Dun and Wharf, and for some space north and south of these rivers, this limestone occurs, in fact, in two rocks separated from each other by beds of red and bluish clay, with gypsum (indistinguishable from some of the upper or Keuper marls of the red-sandstone formation), but in the northern and southern parts this difference does not obtain. Of the two limestones thus separated, the upper one has but a limited extent (see Mr. Smith's 'Geological Map of Yorkshire'), the lower one is almost uninterrupted from beyond the Tyne nearly to the Trent. The upper rock is about 12 yards thick; the lower one reaches 50, or perhaps in some cases 100 yards; the upper one contains almost no magnesia, and lime burnt from it is extensively employed in agriculture; the lower one is very often composed of atomic aggregations of carbonate of lime and carbonate of magnesia, and, both as stone and when burnt to lime, is more useful in building. Its mode of aggregation varies extremely. In many situations (Thorp Arch, in Yorkshire) it is a soft powdery stone traversed nevertheless by veins of calcareous spar; about Tadcaster, and generally between the Nid and the Dun, it is a firm though hardly compact rock, often traversed by sparry veins and full of irregular crystallized cavities. The crystals are generally carbonate of lime, sometimes mixed with oxide of iron. In a few cases sulphate of barytes appears in the form of veins dividing this rock, as at Huddleston, near Ferrybridge, &c. Still less commonly thin veins of carbonate of copper (sometimes apparently epigene, on sulphuret) line the joints of the rock, about Newton Kyme, near Tadcaster, and in other places.

Some of the best building-stone of this description is dug in the quarries of Huddleston, Broadsworth, and Warmsworth, and it is generally really or nearly an atomic combination of carbonate of lime and carbonate of magnesia. (This fact was communicated to us by the late Dr. Henry of Manchester.)

A further state of arrangement of the materials of the rock is noticed in several localities between the Aire and the Dun, where the rocks assume locally and for limited areas the oolitic texture; and, finally, as one of the most valuable building-stones in the range of the magnesian limestone, may be signalized the white limestone of Roche Abbey, which in that noble ruin has stood the ravages of time better than almost any 'freestone' of the north of England.

Farther south, the grain of the rock changes; it becomes continually more and more crystalline, and from Bolsover to Nottingham the magnesian limestone may be described, with little inaccuracy, as a real dolomite, partially debased by small admixtures of sand. The small rhomboidal crystals of this rock are very evident in specimens which we collected many years ago at Mansfield Woodhouse and near Nottingham.

A crystalline structure of the magnesian limestone rock is however not confined to the southern portion of its range, though there it is manifested in connexion with very useful qualities in architecture. In the county of Durham we find it exhibited in the purely calcareous rocks of Hawthorn Hive near Easington, in the romantic, contorted, and broken cliffs and pinnacles of Marsden, and in the singular coralloidal quarries of Building-hill. At Marsden it is curious to notice in near contrast, in the cliff, the flexible laminated limestone, and in the detached pinnacles an equally laminated rock traversed by complete planes of crystalline structure. What does this teach? obviously, the important fact, that, since its deposition in laminæ, the sedimentary mass of carbonate of lime has been subject to a new molecular arrangement, which, predominating over the original structure, has readjusted the particles and generated a new structure. In the same vicinity are brecciated rocks, which seem to require the hypothesis of reaggregation of fragmented portions of previously indurated magnesian limestone beds. Thus various are the aspects of the mineral aggregation of the magnesian limestone of England. These diversities belong almost exclusively to the lower rock, for the upper laminated non-magnesian portion is usually of a uniform close texture, except in the lower beds, which are somewhat cellular (and of little value to the limeburner) at Knottingley.

It should be added that the general colour of the magnesian limestone (lower portion) is white, yellow, rich pale brown, or reddish, while the upper rock is commonly of a grey, smoky, or purplish hue. The rock is usually interstratified with thin clay partings, the lower one very rarely.

The specific gravity of magnesian limestone is usually greater than that of common carbonate of lime. This however may be overlooked in the usual incomplete mode of trying such experiments, unless the observer makes the easy correction due to the absorption of water by many of these stones. Tried in powder (for example, by Leslie's process), the magnesian limestones of England betray, by their weight, their affinity to the dolomitic rocks of the Alps and the Eifel, though the introduction of the magnesia is probably not at all due to the same cause in the two cases.

Professor Sedgwick, in his admirable memoir in the 'Geological Transactions,' on the Magnesian Limestone, has pointed out clearly the most common organic fossils of this rock. We shall only observe here that in respect of fishes (*Palæoniscus*, &c.), mollusca (*Producta*, *Spirifera*, &c.), and zoophyta (*Retepora*, &c.), this rock shows an extreme analogy with the carboniferous system. Its place, by mineral analogies, may be rightly fixed in the pœcilitic system; but, by the affinities of organic existence, it will be classed with the more ancient rocks. Let any one, for example, contrast its marine fossils, whether derived from Durham, Yorkshire, or the Thuringerwald, with those of the muschelkalk; the former are seen to be analogous to forms common in the mountain limestone, the latter to those of the lias. In neither case is the resemblance perfect; the species are not identical, but the result above announced is unequivocal, and must soon be felt in geological classification.

(Sedgwick in *Geol. Trans.*; Smith's *Geological Map of Yorkshire*, &c. Notices of contemporaneous deposits in the midland and southern counties of England occur in Murchison's *Silurian System*; Conybeare and Phillips, *Geol. of England and Wales*, &c.)

MAGNE'SIUM, a peculiar metal, of which magnesia is the oxide, a substance that was originally sold under this name by a Roman canon in the beginning of the eighteenth century. It is stated to have been first procured by calcining the residue left after evaporating the mother-waters of nitre. The method by which it is at present obtained will be presently stated.

The existence of magnesium was first demonstrated by the electro-chemical researches of Sir H. Davy: he found that when moistened magnesia was negatively electrized with mercury, an amalgam was obtained which decomposed water and gave rise to magnesia, by the oxidizement of the peculiar metal amalgamated with the mercury; he did not however obtain a sufficient quantity to enable him to examine its properties. In 1830 M. Bussy procured this metal by decomposing chloride of magnesium by means of potassium. This was effected by placing some small pieces of potassium in a glass tube, with fragments of the chloride put over them; this was fused by the application of heat, and the potassium was allowed to run through it by slightly inclining the tube; light was evolved, and the mass, when cold, was washed with water, which dissolved the chloride of potassium formed, and left the magnesium unacted upon in the state of small globules.

Magnesium is of a white colour, like silver; its lustre is metallic and brilliant; it is very malleable, and fuses at a red heat; in dry air it undergoes no change, but in moist air it is superficially oxidized; it may be boiled in water without suffering any change. When heated to redness in the air or in oxygen gas it burns brilliantly, and, combining with oxygen, becomes magnesia. In chlorine gas it burns spontaneously. It dissolves in diluted sulphuric and hydrochloric acids, with the evolution of hydrogen gas, and it is oxidized and dissolved by dilute nitric acid, and nitrate of magnesia results.

Oxygen and Magnesium, from what has just been stated, combine very readily, but only in one proportion; and the result is oxide of magnesium, or magnesia. The mode in which this substance was first obtained has already been mentioned. It is now procured by decomposing sulphate of magnesia by means of carbonate of soda, and subjecting the washed and dried carbonate precipitated to a strong heat in an earthen crucible; by this the carbonic acid is expelled, and the magnesia, or oxide of magnesium, remains, which has the following properties: it is colourless, inodorous, and tasteless, if pure; it does not, like lime, become hot when mixed with water, and it is very nearly insoluble in it, although when moistened it exhibits the alkaline property of turning vegetable yellows brown; by exposure to the air it attracts carbonic acid, and is reconverted to the state of carbonate, combined with some hydrate. It appears, from various experiments, to be composed of

Chlorine and Magnesium act readily upon each other, the metal burning spontaneously in the gas; it may also be procured by transmitting dry chlorine gas over a mixture of magnesia and charcoal, heated to redness in a porcelain tube. According however to Liebig it is best obtained by dissolving magnesia in hydrochloric acid, evaporating the solution to dryness, mixing the residue with an equal weight of hydrochlorate of ammonia, and projecting the mixture in small portions at a time into a red-hot platina crucible. When the ammoniacal salt has been expelled, fused chloride of magnesium remains, which on cooling becomes a transparent colourless mass; it is inodorous, intensely bitter, very deliquescent, and soluble both in water and alcohol. This salt is one of the saline ingredients of sea-water, and exists in the bittern left after preparing common salt, mixed with sulphate of magnesia. It is also found in some mineral waters, and was formerly called muriate of magnesia.

When a solution of chloride of magnesium is concentrated by evaporation, and exposed to a very cold atmosphere, it yields deliquescent prismatic crystals which contain much water.

It is applied to no direct use; sometimes however the bittern which contains it is decomposed by an alkaline carbonate, for the purpose of forming carbonate of magnesia. It consists of

Bromine and Magnesium may be obtained in combination by dissolving magnesia in hydrobromic acid; by evaporation small acicular prisms of bromide crystallize, which have a sharp taste, are very deliquescent, and soluble both in water and alcohol. When heated in the air these crystals are resolved into hydrobromic acid and magnesia.

Fluorine and Magnesium unite when magnesia is dissolved in hydrofluoric acid. The compound formed is insoluble in water, or in hydrofluoric acid, and is not decomposed by a red heat.

Carbon and Magnesium.—No compound of these is known.

Sulphur and Magnesium do not combine when heated together, nor is a perfect sulphuret formed when sulphur is heated with magnesia. The compound is not soluble in water; by heat the sulphur burns off. When however a solution of sulphuret of barium is added to one of sulphate of magnesia, then, according to Berzelius, sulphate of barytes is precipitated, and sulphuret of barium remains in solution.

Iodine and Magnesium.—A compound of these is obtained when magnesia is dissolved in hydriodic acid; it is very soluble in water, and known only in solution. It is stated also that when magnesia is heated with iodine in water, both iodide of magnesium and iodate of magnesia are procured.

Magnesia, or Oxide of Magnesium, combines with most acids to form salts, two of which are of great importance in medicine; but we shall first mention the

Hydrate of Magnesia.—This is a saline compound, and was first discovered in serpentine in New Jersey, and since in Unst. It is white, with a greenish tint, foliated, and easily splits into thin flexible laminæ. It has a pearly lustre, translucent on the edges. Specific gravity 2·35; hardness 1. It is stated to occur at Hoboken, in New Jersey, in diverging needleform crystals. It is composed of about 31 water and 69 magnesia, with a little oxide of iron and manganese; these are nearly in the proportion of one equivalent each of water and earth.

Hydrate of magnesia may be obtained artificially by precipitating a solution of the sulphate with soda. The precipitate, after drying at 212°, retains about one-fourth of its weight of water.

Nitric Acid and Magnesia readily combine, and yield nitrate of magnesia. The solution is colourless, and extremely bitter. By evaporation it yields, though with difficulty, rhombic crystals, which contain a large quantity of water, and are very deliquescent. It is decomposed at a red heat, and is sometimes found in crude nitre. The anhydrous salt is composed of

1 equivalent of Nitric Acid	.	54
1 equivalent of Magnesia	.	20
Equivalent		74

It is now applied to no use, but is the salt from which magnesia was originally obtained.

Carbonic Acid and Magnesia form carbonate of magnesia, and it has been found native in New Jersey. It has a yellowish white colour, with a flat conchoidal and sometimes earthy fracture. It is opaque, hardness 4·5, and very difficult to break. Specific gravity about 2·8 to 2·9. The purest was found by Klaproth to consist of carbonic acid 49, and magnesia 48, with 3 of water. It may therefore be considered as composed of very nearly one equivalent of acid and one of base.

Carbonate of magnesia, or rather a compound of carbonate and hydrate of magnesia, is artificially prepared for medicinal use by decomposing the sulphate of magnesia by means of carbonate of soda. The carbonate of magnesia is precipitated as an insoluble white powder. This substance, when pure, is colourless, inodorous, tasteless, and unalterable in the air; it is decomposed by the stronger acids with effervescence, and by heat the carbonic acid is also expelled. It appears to be composed of

Sulphuric Acid and Magnesia constitute the salt long and well known by the name of Epsom salt, having been first obtained from a spring at that place. Sulphate of magnesia, which is its proper name, was afterwards obtained by evaporating and crystallizing the bittern remaining after preparing common salt from sea-water; but it was mixed with so much chloride of magnesium that it was extremely liable to become damp. The late Dr. Henry invented a very ingenious process for preparing it from magnesian limestone, in which this inconvenience and impurity are totally avoided.

Sulphate of magnesia is a salt which crystallizes very readily; and although the crystals are usually small, they may be obtained of considerable size by slowly cooling a large quantity of the solution. The primary form of the crystal is a right prism, with a rhombic base. This salt is extremely bitter, readily soluble in cold water, which dissolves an equal weight, and boiling water one-third more. It is but slightly altered by exposure to the air, yet is rather inclined to effloresce. It is not decomposed by heat, but the water of crystallization is expelled. It is composed of

It is extensively employed as a purgative, and for the preparation of magnesia and its carbonate.

This salt combines with various others to form double salts: as, for example, with sulphate of ammonia, of potash, and of soda, forming the ammonio sulphate, the potash and soda sulphates of magnesia, which are all crystalline salts, but they are not important.

Phosphoric Acid and Magnesia are best obtained in combination by mixing concentrated and hot solutions of sulphate of magnesia and phosphate of soda after some hours crystals of the phosphate are obtained. They effloresce slowly in the air, and are soluble in fifteen times their weight of cold water, and by hot water they are decomposed into a subsalt which is insoluble, and an acid one which remains in solution. The crystals are composed of

This salt is applied to no use; combined with ammonia it forms the ammoniaco-magnesian phosphate, a compound which exists in urine, and is a common ingredient in urinary calculi. [CALCULUS.]

Magnesia forms a great number of double salts, and one of these, the magnesian limestone, which is a double carbonate of lime and magnesia, is found in immense quantities in different parts of England. [MAGNESIAN LIMESTONE.] Magnesia is found also in a great number of mineral bodies: as steatite, talc, asbestos, &c.

Magnesian salts are mostly soluble in water; by the addition of soda they yield hydrate of magnesia, and by adding carbonate of soda, hydrated carbonate of magnesia.

The sesqui- and bi-carbonates of potash and soda occasion no precipitation in solutions of magnesian salts, until heated so as to repel the excess of carbonic acid. Phosphate of soda added to magnesian solution gives no immediate precipitate, but on the addition of ammonia an extremely insoluble ammoniaco-magnesian phosphate is formed; and this is the best mode of testing the presence of magnesia, when the requisite precautions are adopted.

MAGNET (derived from the Greek *μάγνης*) is a metallic body possessing the remarkable property of attracting iron and some other metals. It is said to have been found abundantly near Magnesia in Lydia, from which circumstance its name may have been derived. The attracting power of the magnet was known at a very early period, as references are made to it by Aristotle, and more particularly by Pliny, who states that ignorant people called it *ferrum vivum*, or quick-iron; a name somewhat analogous to our load-stone. The same author appears to have been acquainted with the power of the magnet to communicate properties similar to its own to other bodies. When found native, it is generally a heavy ferruginous ore of a dull greyish colour, but the ores of cobalt and nickel also frequently possess the magnetic properties.

The universal law, that reaction is coexistent with action, implies, that iron must react on the magnet, and we find in fact, that if a piece of iron is fixed, and a small magnet be suspended by a string near it, the magnet will then be moved towards the iron; thus all the iron in the mass of the globe acts upon a magnet. It is also now known that electrical currents influence magnetic bodies [ELECTRO-MAGNETISM]; while heat has an influence on magnetic intensity. Hence it follows as a mechanical consequence, that if a magnetic needle or cylinder be suspended by its centre of gravity, so as to be free to move in any direction round that point, it will not take an arbitrary position like unmagnetized bodies, but must take a specific direction, namely, that which represents the resultant of all the magnetic forces to which it is subject. Its position in a given place can be defined by two angles; the one called the *variation* or declination, the other the *dip*. The first is the angle formed by the vertical plane in which the needle lies with the plane of the meridian; the second the inclination of the line of the needle to the plane of the horizon. The latter is avoided in the compass-needle by sustaining it horizontally on a point which is necessarily different from its centre of gravity, and the variation is the angle made by the direction of the needle with that of an exact and horizontal north-and-south line. This property of the needle is called its polarity, and is a consequence of its other properties above noticed; the fact however escaped the notice of the Greeks and Romans of antiquity, but the Chinese appear to have been acquainted with it from a very remote date. It is the most useful of the known properties of the magnet, being of the most essential importance to the mariner, when the magnet is constructed in the form of the compass-needle.

Dr. Gilbert, who was physician in ordinary to Queen Elizabeth, states that P. Venetus brought a compass from China in 1260. Gilbert bestowed much attention on the subject of magnetism, and to some extent inculcated the doctrine of gravitation, by comparing the earth to a great magnet. His theory on this subject is given in a work entitled *Tractatus sive Physiologia nova de Magnete* (1600), and the term 'poles of a magnet' arose from that theory, which is remarkably consonant with the notions of the present day, for the north pole of the magnet he denominated the south pole, in connection with his theory, while Poisson, in his elegant 'Memoirs on Magnetism,' calls the magnetic fluid at that extremity of the magnet the *Austral Fluid*, because, as like electricities repel [ELECTRICITY], so, on his hypothesis of the magnetic fluids, that occupying the north end of a magnetized needle is repelled by the austral fluid of terrestrial magnetism.

The application of the compass to the purposes of navigation must speedily have led to the discovery of its variation, and in the 'Life of Columbus,' written by his son, it is distinctly assigned to that celebrated man; and though its amount in 1492 must have been small in France, Spain, &c., yet it was doubtless a very observable quantity in many of the regions visited by Columbus. Some have carried back the date of this discovery to the year 1269, but on very doubtful grounds. When its amount came to be observed with some accuracy, we find it at Paris, in 1541, 7½° E.; in 1550, 8½° E.; in 1580, 11½° E.; in 1630, 4½° E.; and at Rome, in 1670, 2° W. At the present moment it has passed its maximum in London, and is now moving easterly.

It is not improbable that Columbus was acquainted also with the diurnal variation, but nothing very accurate on this subject was known before the numerous and valuable observations made by Canton, in 1750. He showed that the needle vibrates, during the day and the night, through an arc as great as 13½′ in the midsummer, the minimum 7′ occurring in the winter season; he ascribed the diurnal variation to the action of solar heat affecting the intensity of the magnetism of the earth. The principles of thermo-electric currents were at that period unknown, but Hooke in 1684 showed that iron and steel rods could be magnetized, by rapidly heating and cooling them in the magnetic meridian. Graham, instrument-maker, of London, was the the first who distinctly announced the diurnal variation, in 1772; the maximum declination being then 14° 35′ west. The variation of the variation was first observed by GUNTER.

The *dip* was first observed by Robert Norman in 1576. His mode of adjusting the compass-needle led him to this discovery; for he accurately balanced the needle on its pivot, previous to magnetizing it. After it became a magnet, it would no longer balance on the same point, without attaching a small weight at the south extremity. When freely suspended by the centre of gravity, the north extremity became depressed; the dip then being about 71° 50′. The dip undergoes diurnal variations, as well as the declination; but observations on the former are far the most difficult. The dip also changes by elevating the needle to considerable heights; on which subject Biot has made some very delicate experiments. A very simple law relative to the amount of the dip at different parts of the earth's surface was remarked by professor Krafft, of St. Petersburg, in 1809; namely, if we measure the latitude from the magnetic equator, the tangent of the dip is double the tangent of such latitude. Mr. Barlow has illustrated this law by experiments on magnetized iron *balls* acting on small needles at the surfaces; and Biot has deduced the same law from theory.

The law of the magnetic forces was a long time undiscovered: Newton supposed it to follow the inverse cube of the distance, or some higher power; for in his experiments, the variation of intensity and the effect of the mutual influences of the magnetic fluids in the bodies themselves being overlooked, an erroneous result was necessarily consequent. However, Mitchell, by a careful revision of the experiments of Dr. Brooke Taylor and of Hauksbee; Coulomb, by his elegant apparatus, the torsion balance; Biot, by the method of observing the times of the oscillations of the small needles acted on; and finally, Hansteen of Christiana, by a series of refined experiments and calculations, have demonstrated the true law of magnetic action; namely, directly as the intensity, and inversely as the square of the distance.

One essential property by which a magnet differs from soft iron under the magnetic influence, is this: if we separate a magnetic bar into any number of minute parts, each such part will be endowed with polarity, similar to the whole: the position of those poles, or foci of greatest attraction, is permanent in a magnet of a given form; but in soft iron it will change when the distance of the iron from the influencing magnet is altered.

Halley was sent out, under William and Mary, with the command of two ships, to make magnetic observations in different latitudes, both in the Atlantic and Pacific (in 1698-9); and was the first who constructed a magnetic chart, which possessed at the time great merit for accuracy: the most valued at the present day are those by Hansteen, constructed from observations subsequent to Halley, by various scientific travellers and nautical men, such as Humboldt, Ross, Parry, Scoresby, &c. [MAGNETISM.]

During a thunder-storm, the poles of a magnet are frequently inverted, the explanation of which belongs to ELECTRO-MAGNETISM: and the appearance of the aurora borealis is often attended with vibrations of the compass-needle, to the extent of several degrees. The actual mode in which the aurora is produced being still unknown, it is impossible to decide whether the aurora is itself the cause of this magnetic phœnomenon, or whether both are attributable to some unknown common cause.

MAGNETIC INTENSITY. When a magnetic needle is freely suspended by its centre of gravity, it is then acted on by all terrestrial bodies containing the magnetic fluids, whether in a fixed state, as in loadstone-ores, or in a state susceptible of change, as in masses of soft iron, and also by electrical currents, whether produced by the chemical changes which various substances in the globe continually undergo, or arising from the unequal distribution of heat both in the interior of the earth and on the surface in different latitudes. The direction of the resultant of all such forces may be regarded as possessing parallelism throughout the extent of the needle, and the latter acquires in consequence a like direction in the plane of the magnetic meridian, of which the position becomes in this manner known.

If a needle thus suspended be made to oscillate in the plane of the magnetic meridian, and the time in which a certain number of oscillations are performed be observed, and thus the time of a single oscillation deduced, the connection of this time with the intensity of the magnetic force is expressed by the formula $t = \pi \surd\left(\frac{l}{F}\right)$ similar to that used for the common pendulum. In this equation t represents the time of one oscillation, π the number 3·14159, l the distance between the centres of oscillation and gravity, and F the accelerating force of magnetism. Hence we deduce also $F = \frac{\pi^2 l}{t^2}$; consequently when one and the same needle is used in different experiments, the force F is inversely as the square of the time t of one or of a given number of oscillations. But it is in practice extremely difficult to produce oscillations in the magnetic meridian, and ingenious contrivances to that end have often been suggested and used, but the object of ascertaining the relative value of F is equally attained by supporting the needle horizontally, as in the compass, and observing the time of the horizontal oscillations. If θ represent the dip, then by the resolution of forces the horizontal part of the magnetic force is $F \cos \theta$; if now T represent the time of (suppose 300) oscillations, then by the preceding formula we must have $F \cos \theta$ inversely proportional to T^2; let F', θ', T', represent quantities corresponding to F, θ, T, for a different latitude or longitude, then $\frac{F}{F'} = \frac{T'^2 \cos \theta'}{T^2 \cos \theta}$; by which formula the relative intensities of terrestrial magnetism at different places may be ascertained with little trouble.

The times of 300 oscillations in seconds at the following places are taken from a table computed by Hansteen:—Stockholm 815, Edinburgh 820, Christiansand 820, Oxford 780, Danzig 770, Gottenburg 812, Liverpool 801, London 775, Berlin 760, Paris 753, Lübeck 776, Altona 776, Johnsknuden 861, Christiania 814, Ingolfsland 833, Copenhagen 788, Breslau 741.

The locus of all the points at which the intensity of terrestrial magnetism is the same quantity as at one given place is called the *isodynamic line* passing through it. These lines are generally of double curvative; but neglecting this, which may also be said of the lines of equal dip, they run generally parallel to each other and to the latter lines, in the temperate zone, but in other cases these two classes of lines intersect at a considerable angle. M. Hansteen states that the intensity of magnetism is less in the southern than in the northern hemisphere. M. Biot has given a formula deduced from hypothetical considerations, which has been found nearly coincident with the observed cases of terrestrial intensity, viz. intensity $\propto \frac{1}{\surd(4-3\sin^2\theta)}$: θ being the dip as before.

As the declination and dip have diurnal variations, so also has the magnetic intensity; the minimum being between ten and eleven in the morning, and the maximum in about six hours afterwards. The intensity is also greatest in December, and least in June.

An interesting series of observations made by M. Quetelet, of Brussels, shows that in the gradual ascent from Geneva to the Col de Balme the intensity of terrestrial magnetism increases; for instance, the horizontal intensity at the village Simplon is greater than that at Bonneville nearly in the ratio of 44 to 43.

Similar methods (and sometimes the balance of torsion) have been used to discover the relative intensities of magnetism as distributed in bodies; in straight and narrow laminæ it has been found by Coulomb to be nearly proportional to the square of the distance from the middle point.

MAGNETISM. If we take a natural or artificial magnet, and, spreading over a piece of paper a quantity of fine iron filings, place the magnet on the paper, on taking it up, we shall find that the iron filings are attached to it in some degree over all its surface, but they will be principally accumulated at two points situated near the ends of the magnet; these points are called the poles of the magnet. Sometimes when a magnetic bar is rolled amongst iron filings, we may find several such points along the bar; the magnet is then said to have consecutive points. At present we shall consider only the first or simple case of two poles, which we may represent by the letters N and S. When a needle formed of this material is suspended horizontally on a pivot armed with agate, it assumes a particular direction, nearly north and south. [MAGNET.] The pole N, at the north extremity of the needle thus adjusted, is commonly called the north pole of the needle; the other, S, the south pole, though the contrary names, as used by Dr. Gilbert, would be more correct in connection with the theory of magnetism.

If we now bring a piece of soft iron near the pole N, it will be attracted to that pole and become attached to it, so that the exertion of a mechanical force is necessary to separate them. In this way a magnet held vertically will sustain a piece of iron, provided the weight of the iron does not exceed the magnetic force. The pole S has a similar attractive power on iron; the cause of this attractive power is called MAGNETISM.

We have observed that in a magnetic needle placed horizontally on a pivot, the pole N is turned northwards, and S southwards, nearly: if such a needle be attached to a piece of cork floating on water, it will adjust itself to this direction, the deviation of which from the true north-and-south line is the declination of the needle. If now we invert the position of the needle, so that S is brought into the place previously occupied by N, and *vice versâ*, the needle and cork will make a complete revolution, and acquire its original position. Hence we see a distinction between the magnetisms *predominant* at N and at S; the former is called *Austral*, and the latter *Boreal* magnetism. It will be easy to observe the analogy between the mutual relations of the two magnetisms, and those of positive with negative electricities.

We must insulate a conducting electrized substance in order to preserve its electricity, but this is not necessary in the case of a magnet; each fragment of the latter is itself a magnet, possessing its north and south poles, and the same view may be extended to its constituent particles. A nonconducting energy, called the *coercive power*, exists therefore in magnetic substances, by which the loss of magnetism when developed is prevented, and by which also the poles N and S are situate in a determinate position relative to the body of the magnet. This is not the case with soft iron, which has not the coercive force.

The force of magnetism is exerted without alteration through substances which are not magnetic; the same is true with respect to the electrical forces when nonconducting bodies are interposed in the direction of their action. On the other hand, the effect of the magnetic forces is considerably modified when substances which are capable of becoming magnetic by influence are situated near the magnet; and a similar effect takes place by the decomposition of the neutral electricities when under the influence of an electrized body. [ELECTRICITY.] The transmission of the magnetic force through interposed bodies may be observed familiarly by placing a common sewing-needle on a smooth horizontal board, and moving a strong magnet underneath the board: the needle will roll or revolve along the board according to the peculiar motions given to the magnet.

Let us next consider the action of magnets on each other. For this purpose make two magnets or magnetic needles to float on water, distinguishing the poles of one as before by N and S, and of the other by N′ and S′. Bring either the pole N near to N′, or S to S′: the needles or magnets will separate to a greater distance, and with the greater energy the nearer these poles are placed to each other. On the contrary, if we bring N and S′ near each other, the needles will approach and unite those points, and the same happens when the points N′ and S are made contiguous: hence this law—*magnetisms of the same name are mutually repulsive; those of contrary names are mutually attractive.* In the article ELECTRICITY, above referred to, we have shown that the same law is true with respect to the two electricities.

The mass of the globe contains various sources of magnetism [MAGNET]; and since a magnetic needle freely suspended acquires a determinate position, it follows from this law that the magnetism at the south extremity S is Boreal, that is, of the same name as the terrestrial magnetism which is predominant in the northern hemisphere, being repelled therefrom; and the magnetism at the north extremity N is for a like reason Austral. The law of magnetic force at different distances is expressed by the inverse square of the distance: the best mode of verifying this law is by observing the times of the oscillations of a small fine wire, suspended in a plane perpendicular to the magnetic meridian (in order to neutralize the magnetizing influence of the earth), and subjected to the action of a powerful magnet.

We can, by combining these laws, explain the manner in which soft iron, cobalt, and nickel are attracted or suspended by a magnet. These metals, when unoxygenated, contain both the austral and boreal magnetism in a combined state, in consequence of their want of coercive power. When a piece of soft iron is brought near the pole N, which contains the austral fluid, the austral magnetism of the iron is repelled to the farther extremity, and the boreal attracted to the nearer extremity of the iron relative to the point N: this disposition of the fluid takes place immediately, and the law of force above announced relative to the distances causes the attraction of the fluid at N, on the boreal fluid of the soft iron, to exceed its repulsion on the austral, which is more remote from N: the total effect, in virtue of this excess, is therefore necessarily attractive. When the iron however is removed from this influence, the natural magnetisms again recombine. This will not be the case if, instead of soft iron, we use hardened iron or steel: the decomposition of the natural magnetisms takes place with greater difficulty, in consequence of the coercive power which protects their actual disposition; but if we use a powerful magnet at one extremity of a steel needle, or, which is more effectual, a pair of strong magnets at both extremities, the north pole of one and the south pole of the other being brought in contact with the needle, the decomposition will be partially effected, and will likewise be retained by the same coercive power which opposed its development; and agreeably with the magnetic laws of repulsion and attraction, that point of the needle in contact with the south pole will become a north pole of the needle, and the other a south pole. This method of producing magnetism is liable to the objections both of producing feeble magnetism and also producing consecutive points.

The quantities of the austral and boreal magnetic fluids in all magnetic bodies are equal; for when we bestow magnetic qualities on iron or steel by the influence of loadstones, hammering, sudden cooling in the magnetic meridian, &c., no new magnetism is communicated; but the natural magnetisms, which previously neutralized each other, are now decomposed. Again, if a magnetic needle be freely suspended by its centre of gravity, the action of terrestrial magnetism produces no linear motion, but only imposes a direction on the magnetic axis: now all the boreal fluid in the globe attracts all the austral fluid of the needle, and *vice versâ*, while the like fluids in both repel: hence a motion of progression would be generated, unless the resultant of the repulsive forces on the needle was exactly equal and of an opposite direction to the resultant of all the attractive forces; and the rotatory motion of the needle shows that the points of application of these forces are different; but the intensity of terrestrial magnetism may be regarded as uniform throughout the extent of the needle, and its direction parallel. In order therefore that the resultants should be equal and contrary, the sums of the boreal and austral forces of the needle must be equal. In this respect magnetism resembles the natural electricities of all substances.

The development of magnetism in bodies, whether by terrestrial action or the influence of loadstones, is analogous to the decomposition of the natural electricities in a system of conducting bodies separated by non-conductors under the influence of an external body and their own natural action; hence when magnetism is communicated by a loadstone even when in contact the latter loses none of its own magnetism, as it acts solely by influence; whereas in conducting electrified bodies, contact will communicate electricity; the coercive force of magnets therefore extends even to their surfaces. In fact the reaction of the substance magnetised by influence tends to a further decomposition of the fluids of the magnetising body, and thus gives it greater energy, unless when it is magnetised to saturation, that is, when the internal magnetic forces are equal to the coercive power; for then any further development of the fluids would be only temporary, and a reunion would take place immediately.

The dipping-needle is a magnetic needle, the opposite poles of which possess equal magnetic intensities. It is attached to the centre of a vertical circle, and its motion is confined to the plane of this circle. The circle has a motion in azimuth about a vertical axis, and within a fixed horizontal circle, both circles being graduated. When the vertical circle is turned round its axis until the needle acquires a vertical position, the plane of the circle is then perpendicular to that of the magnetic meridian, and hence by means of the horizontal circle the position of this meridian plane becomes known. The vertical circle with the needle is now brought to coincide with the meridian plane, and the angular depression of the north pole of the horizon, or more directly of the magnetic axis, may be read off the graduated limb of the vertical circle, and measures the dip. The right line joining the north and south poles of the needle is nearly coincident with the magnetic axis, but the latter may be ascertained more accurately by inverting the needle and taking the mean direction between its two positions of equilibrium. There are other methods of adjusting the dipping-needle, but in every method it requires great delicacy and minute attention in all parts of the adjustment.

If we place a bar of soft iron, suspended by a collection of silk strings at its middle, in a direction parallel to the magnetic axis of the dipping-needle, the action of terrestrial magnetism will have full effect on the bar, its natural magnetisms will be decomposed, and it will acquire a polarity similar to that of the needle, its poles repelling the similar poles of the needle, and attracting the contrary poles. Its want of coercive power prevents it from retaining the polarity of its different parts when the bar is moved into other positions; for if we invert the position of the bar, that point which was primitively the north pole will now become the south, and *vice versâ*, under the effects of a new decomposition of its magnetisms by terrestrial influence. If however the bar be left for a long time in the direction of the magnetic axis, so as to acquire some oxygenation, or if it be heated to a red heat and suddenly cooled by immersion in water, it will acquire a coercive force, and become permanently magnetic. Iron crosses, weathercocks, &c., which have been long kept in a fixed position, or have been struck by lightning, acquire magnetic properties in the manner above described.

It is a remarkable circumstance connected with the change of molecular disposition caused by the action of heat, that if we gradually heat a bar of iron, the intensity of its action on a magnet increases, and arrives at a maximum when the bar is brought to a cherry-red heat; with higher degrees of heat the intensity is diminished, and is totally inappreciable when the bar has reached a bright white heat; on cooling it recovers its powers of action by similar steps, and the same law holds true if the magnet be heated instead of the bar. Hence in producing the greatest development of magnetism by influence, we see the advantage of using iron or steel bars at a red heat.

Magnetism may be developed in iron, steel, cobalt, and nickel, by other means than the influence of bodies already magnetised, as twisting, hammering, electrical discharges, and galvanic currents. [ELECTRO-MAGNETISM.] If we place a bar of iron in a vertical position, and give it a series of slight blows with a hammer or poker, it will acquire a feeble degree of magnetism; hence it happens that the anvils and other tools employed in smithies are endowed with magnetism. In all such cases the mechanical operations tend to bestow a coercive power, while the terrestrial magnetism separates the fluids in the body.

Cavallo, Bennet, and Coulomb remarked the indications of magnetism given by various substances, as copper, silver, &c. It is particularly observable in hammered copper, and scarcely perceptible when the copper has been cast, an attention to which circumstance is of considerable importance in shipbuilding. Coulomb formed very fine needles of various substances, and suspending them by silk strings between the opposite poles of two powerful loadstones, found that they were acted on by the latter. This phenomenon is attributable to the existence of minute quantities of iron or iron compounds in these different bodies. The intensity of the magnetic action Coulomb found from direct experiments to be proportional to the quantities of iron contained in the bodies, and he afterwards applied this principle to discover the quantity of iron contained in impure metals.

From the preceding observations on the properties of the magnetic fluids it will be easy to understand the principles upon which the various modes of constructing artificial fluids are founded, which we shall now briefly notice. The earliest method of magnetising a bar of hard iron or steel was by drawing it throughout its whole extent at right angles over one of the poles of a strong magnet. In this case if we suppose that pole which contains the austral fluid to be used, the first contact with the bar decomposes its neutral magnetisms, attracting to the point of contact the boreal and repelling the austral; the successive parts of the bar are subject to a similar decomposition of their fluids, but it is evident that the effect of each previous decomposition neutralizes the succeeding, except at the extremities; the magnetism thus developed is therefore feeble, and apparent only at the extremities of the bars, or in some consecutive points formed by peculiarities in the material of the bar, or in the mode of operation. Dr. G. Knight greatly improved the mode of magnetizing bars in the following manner: he joined two strongly magnetized bars by their ends bearing contrary names, and placing on them in the direction of their length a small steel bar heated to a cherry-red heat, with its middle on the point of junction of the magnetic bars, he made each of them to rub on the corresponding extremity of this steel bar, and the latter when removed was found to be strongly magnetized. In this method not only does the presence of the second magnet favour the decomposition of the magnetic fluids, but the intensity of the action of the magnetic forces is greatly increased by the elevated temperature of the steel bar.

Du Hamel placed two steel bars of equal length parallel to each other, connecting their corresponding extremities by pieces of soft iron interposed; then taking two bundles of magnetic bars, he united their poles of contrary name near the middle of one of the steel bars, and by inclining the bundles made one of them pass towards one extremity of the other bar, the second passing in the contrary direction, and then successively repeated the operation, when both the steel bars became strongly magnetized, but with contrary magnetisms at the corresponding extremities of each. In this method the decomposition of the neutral magnetisms of the interposed pieces of soft iron adds to the effect produced by the contact of the magnetised bundles with the steel bars.

Epinus, adopting a similar method, preferred interposing strong magnets instead of soft iron, the relative position of the poles of the two magnets being reversed; Coulomb combined the advantages of these different methods by composing his magnetised bundles of bars at a cherry-red heat. A fine steel needle may be very strongly magnetised by being placed in the axis of a wire twisted into the form of a helix, the extremities of which are brought in contact with the wires of a powerful galvanic battery. The poles of a bar magnetized to saturation are near its extremities, within generally a few lines, while the intensity becomes insensible at the distance of a few inches; in a thin bar the intensity may be represented by the difference of the ordinates of two logarithmic curves, the origin of one being at the austral, and of the others at the boreal extremity of the needle.

When bodies containing neutral magnetisms are made to rotate rapidly round an axis, the magnetism becomes developed and acts on the needle; thus a plate of copper made to revolve rapidly in a horizontal plane will influence a compass-needle placed over it, and produce in it a rotation in the same direction, on which subject several valuable observations have been made by M. Arago, Sir John Herschel, &c. It has also produced a second mathematical memoir from M. Poisson, in which the mechanical force generated by rotation is introduced into the general equations deduced from his theory of the distribution of magnetism in bodies.

The consideration of the distribution of magnetism throughout the globe has led to various explanatory hypotheses since the time of Halley; the position, the number, and the motions of the points which may be regarded as poles of terrestrial magnetism, have been all subjects of discussion and of opinions formed on inconclusive grounds. The excellent tables and maps of Hansteen have given a greater degree of certainty to this subject. The French government having lately sent out an expedition for geographical and scientific discovery, the report of which may be shortly expected; and the British government having appointed Captain James Ross with a view to similar objects in the Pacific, we shall defer to the article TERRESTRIAL MAGNETISM an account of the dip, variation, and intensity, at different parts of the earth, as well as the consideration of the magnetic equator and poles.

Magnetic observations are now generally made in Europe in observatories, and also by scientific travellers; and something valuable on the subject of terrestrial magnetism is daily added to our previous knowledge.

MAGNETISM, ANIMAL. [ANIMAL MAGNETISM.]

MAGNIFYING POWER. [MICROSCOPE; TELESCOPE.]

MAGNITUDE. This term is generally used synonymously with quantity, and is sometimes even confounded with number. The distinction between the first two terms is not more marked than this:—he who answers the question 'how much?' describes the quantity, and he who answers 'how great?' describes the magnitude. But since magnitude is generally used in our language as applied to amount of space, we may best describe our own idiom by laying down quantity as the general term, and stating magnitude to mean usually the quantity of space. The term however must be considered, in a mathematical point of view, as originating with Euclid (whose word is μέγεθος), and it is used by him, not particularly as applied to space, but also to everything which admits of the introduction of the notion of greater or less. In this sense then, we have many magnitudes (all moral qualities for instance) which are not the object of mathematical reasoning. So necessary is the notion of magnitude to our conception even of things which we cannot measure, that we borrow idioms from subjects within the province of mathematics. Thus we speak of force of mind, and of it being greater in one individual than in another. According to the definition of magnitude, namely, 'that of which greater or less can be predicated, when two of the same kind are compared together,' it follows that we include both mental as well as material objects of conception. But the mathematics interpose the postulate that no such object can be made matter of exact reasoning, unless in cases which admit of the comparison being performed according to some method the results of which shall be self-evident, and inseparable from our notion of the thing measured. Let A and B be two magnitudes of the same kind; they are then, and then only, the objects of mathematical comparison, when other magnitudes equal to A and B can be found, and added together as often as may be desired; and when, moreover, any collection of As can be compared with a collection of Bs, so as to ascertain which is greater or less than the other. Angles furnish an instance of magnitude the conception of which is exceedingly vague in the mind of most beginners, but which takes precision and certainty in the course of mathematical study. Magnitudes, thus capable of comparison, are the objects of the doctrine of PROPORTION. [See also NUMBER; QUANTITY.] That part of geometry which precedes proportion considers only the simple alternative of equal or unequal, modes of inequality being necessarily deferred until after that consideration.

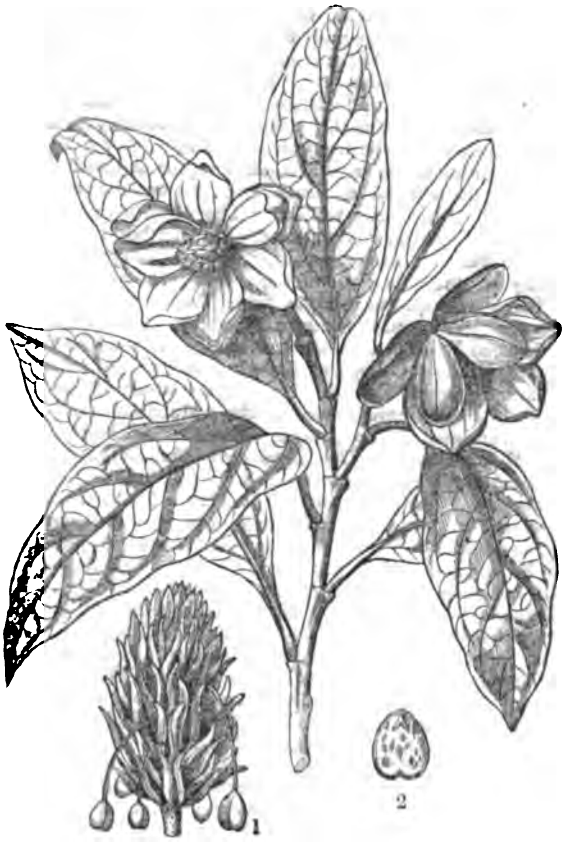
By the magnitude of any bounded space the mathematician means the results of measurement which will be described in SOLID, &c. DIMENSIONS: but the common [illegible] refers to that which the mathematician calls for distinction *apparent* magnitude. It is correct, in the common meaning of the term, to say, that a man at a little distance from the eye is larger than a remote mountain. In thus judging of objects, the angles which they subtend at the eye form the means of comparison. Experience, derived from a combination of sight and touch, teaches us how to make those deductions which are necessary before we can [illegible] the absolute from the apparent magnitude.

It is soon found that an object, as it recedes, grows smaller, that is, subtends a less angle. It is also seen that the recess is accompanied by a loss of brightness and distinctness. The former is a consequence of the loss of light which takes place in its passage through the air; were [illegible] not for this, the same object would be equally bright at all distances; for though the quantity of light which enters the eye is diminished by increase of distance, yet the surface from which the light appears to proceed is diminished in the same proportion. The loss of distinctness is a consequence first of the loss of light, next of the different proportions in which different colours are lost: the effect of the interposed atmosphere amounting to laying on more or less of the [illegible] colour of the atmosphere over the whole. Our perception of magnitude depends both on the subtended angle and on the distinctness: we learn from experience, that of two objects seen under the same angle, the less distinct, as being more distant, must be the larger. That habit is our [illegible] can readily be shown by producing instances in which we are deceived, the object being either such as is not commonly seen, or seen under unusual circumstances. A colossal statue mounted on a column does not suggest the [illegible] of a man of unusual size to persons in general, unless when some person mounts the same height, and affords means of comparison. In a fog, which diminishes the distinctness of objects, but does not affect the angles under which they are seen, these objects are sensibly increased in apparent size; and distant hills appear nearer in a clear day than in a hazy one. Those who wear spectacles may satisfy themselves, by breathing on the glasses, and watching an object as the moisture evaporates, that increase of distinctness gives apparent approximation.

The angle subtended by an object is inversely as its distance, which is sufficiently near for common purposes when angles are small, which is generally the case. A man of six feet high, at the distance of a hundred feet is seen under an angle of 3° 26′. The sun is seen under an angle of 32′, and the moon under an angle of 29½′ to 3[illegible]

MAGNOLIA'CEÆ, an important natural order of [illegible]minous polypetalous Exogens, consisting of bushes and trees, inhabiting the temperate parts of both the Old and New World. They have the numerous disjoined carpels and hypogynous stamens of Ranunculaceæ, to which they are closely allied; they differ not only in their arborescent habit, but in the young leaves being enveloped in stipules either horn-like and convolute, or bivalved, which are thrown off as the leaves unfold. The flowers are usually large, sweet-scented, and the leaves are firm, broad, and [illegible] in consequence of which many of the species are objects of cultivation in all civilized countries. In England, where they are exotics, they are among the most highly valued of ornamental plants, and every species which can bear our climate, or which will thrive in conservatories, has been collected with great care, whenever opportunities have offered, so that few now remain to be imported. Among the most ornamental of the hardy kinds are the M. grandiflora of Carolina; M. glauca, of which there are several varieties; M. macrophylla, the flowers of which are among the largest in the vegetable kingdom; and the Tulip tree, Liriodendron tulipifera, a large tree with singular truncated leaves. In Bengal the air is often perfumed with the fragrance of the Tsjampac, a species of Michelia; while in China and the Malayan Archipelago others are equally well known for their ornamental characters. Nor are the plants of this order less useful than beautiful. It is probable that they are all valuable for the febrifugal qualities of [illegible] bark. Magnolia glauca is among the best bitter and aromatic species known in medicine, and the Tulip-tree affords to the North American settler a substitute scarcely inferior to it.

The genera Talauma and Magnolia have the very singular property of dropping their seeds out of the back of the seed-vessels when ripe, allowing them to hang down, each suspended by a long extensible elastic cord, composed of delicate spiral vessels



A branch of Talauma pumila.

1, a head of ripe fruit with the seeds hanging down by their cords; 2, a vertical section of a seed, showing the minute embryo lying in copious albumen.

In consequence of the seeds of Magnoliaceæ containing an abundance of oil which often becomes rancid soon after they are gathered, it is difficult to transport them to a considerable distance in a living state. The best method of succeeding in that object is to pack the seeds in earth as soon as they are ripe, pressing them close and securing them in a box. Under such circumstances they will preserve their vitality for several months.

MAGNUS, ALBERTUS. [ALBERTUS MAGNUS.]

MAGO. [CARTHAGE.]

MAGO. [COLUMELLA.]

MAGPIE. [CORVIDÆ, vol. viii., p. 68.] In addition to the habits of this bird and its geographical distribution stated in the article above referred to, M. Temminck quotes M. Boié as authority for its building its nest in edifices, and as being very common in Norway. It lives as high up as Lapland, and is common in the Morea. Dr. Von Siebold and M. Bürger observed it in Japan, where it is known by the name of *Kasasi*, and is precisely identical with the European magpie.

MAHÂBALIPURAM ('the city of the great Bali'), a village on the Carnatic coast, in 12° 36′ N. lat. and 80° 16′ E. long., about 35 miles south from Madras. In the immediate neighbourhood of this village are a great number of antient sculptures in a high state of preservation. They consist of groups of human figures, lions, elephants, bulls, monkeys, and cats, all of the natural size, and various other animals or monsters. These figures are all cut out of solid blocks of granite, and were evidently connected with mythological subjects.

In the face of a granite rock behind the village is an excavated gallery with pillars, and near to it is another large excavation, the walls of which are covered with sculptures, having reference to the Hindu mythology. To the north of the village is a temple containing a statue of Ganesa, thirty feet high, which is cut out of a single block of granite; and about half a mile on the south side is a group of temples from seventeen to thirty-six feet in height, formed of the same material. Some smaller caves are seen in the neighbourhood, and everywhere about are scattered fragments of sculptures similar in character to those above described.

A temple dedicated to Vishnu, a tank, and some architectural ruins on the neighbouring plain, are held by the natives to be of an equally remote antiquity with the sculptures, but this opinion does not appear to be well founded. The inhabitants have a tradition that the city of the great Bali stood on the shores opposite to the site of the present village, but is now covered by the sea. It appears however that the opinion of the sea having swallowed up or washed away several pagodas is groundless, and it is even doubtful if the tradition above referred to does not rather apply to a place on the Malabar coast, where the memory of a prince called Balin is preserved and celebrated by an annual festival. It appears that the true Sanscrit name of this place on the Coremandel coast is 'Mahâmalaipura,' or 'the city of the great mountain.'

(Babington, *On the Sculptures and Inscriptions at Mahâmlaipur*, in *Asiatic Transactions*, vol. ii.)

MAHÂBHÂRATAM, or BHARATAM ('belonging to Bhârata and his descendants'), the most celebrated epic poem of the Hindus after the 'Râmâyana.' A passage in the introductory part of the work (1, 2296) has given ground for the assertion that it contains the round number of a hundred thousand distichs or slocâs; but in order to complete this enormous amount, the 'Harivansa,' a mythological history of Krishna, and sundry other pieces, have been added. The eighteen component fictions (Parva) of the 'Mahâbhârata' contain about 85,000 slocâs, and even these may be reduced to 24,000 distichs, of which the original 'Bhârata,' without its episodes, is said to have formerly consisted. (1, 101.) The principal subject of the 'Mahâbhârata,' to which its middle sections particularly are consecrated, is a long civil war between two dynasties of antient India, the Kurus and Pându. Both were descended from Bhârata, king of Hastinapur, whose first-born son, Dhritarâshtra, the father of Duryodhana and the Kurus, ought to have succeeded to the throne; but this prince being blind, the sceptre was seized by his cousin Yudhishtiras, the eldest of the five Pându princes. At first the usurper was driven off by his uncle Duryodhana, and even banished to a wilderness for twelve years; but as the Pându brethren were favoured by their friend and ally, the heavenly Krishna, and as they were themselves, according to the legend, begotten by several deities, after a long struggle against the Kuru princes, and after many perilous adventures and bloody exploits, they were finally established in the sovereignty of India.

In this main texture of the 'Mahâbhârata' is interwoven a great variety of episodes; or more properly speaking, the history of the Pândus and Kurus is the leading thread by which an immense collection of antient traditions, moral reflections, poetical descriptions, and popular stories of every kind, has been connected. It is very important to observe that these accessory elements, which now form almost three-fourths of the whole epopee, are stated in the poem itself not to be constituent parts of the original 'Bhârata;' in fact they are for the most part very loosely inserted; and as many of them are epic productions of considerable length, the principal theme is not only frequently interrupted by intervening episodes, but often totally lost sight of, even when the most active progression should be expected. Thus, for instance, the metaphysical system of Patanjali is propounded by Krishna, in the eighteen lectures of the much admired Bhagavadgîtâ, just when the army stands disposed in full array and ready for battle. Besides a vast number of various short tales and fictions of every description occasionally inserted, the episodical compositions of the 'Mahâbhârata' may be divided into two general classes of a more distinct character and of peculiar importance. The first class, to which the early sections of the 'Mahâbhârata' are particularly consecrated, is occupied in solving theogonical and cosmogonical problems, blended with those wild and fantastical conceptions by which the metaphysical mind of the Hindus is so deeply attracted. To these, in the last chapters of the work, and after the conclusion of the great war, are added didactic and moral episodes on religious duties and sacrifices, on solitary and penitential life, and on final beatitude, forming almost a complete system of Indian ethics, and a compendium of the Brahminical faith. The second class of episodes, which may, although in some respect improperly, be called historical, consist of various and ample traditions of former epochs, and are occupied in recording the origin, genealogy, and history of antient kings and heroes; in giving an account of their government and practice of warfare, their individual adventures, and their splendid actions; and in exhibiting their piety and devotion in fulfilling those duties of a religious life by which the favours of the heavenly beings are to be acquired. These and similar narratives are chiefly accumulated in the third and longest section of the 'Mahâbhârata,' called Vanaparvan (book of the forest), where they are told by the Brahminical sage Markhandeya, for the purpose of entertaining, consoling, and animating the dejected spirit of the Pandu princes during their exile in the wilderness. In this respect the episodical pieces of the 'Mahâbhârata' may be compared with the rhapsodies sung by Phemius and Demodocus in the Homeric poems, and as many of them are marked with a peculiar simplicity of manners and customs, they might almost seem of an older date than the main body of the epopee, of which they are totally independent. This leads us to the original composition of the 'Mahâbhârata,' which in the introductory part of the poem is thus related.

The most celebrated sages, with their disciples, being assembled at a splendid sacrificial festival, the venerable Krishna Dvaipâyana, with the surname of Vyâsa, who had been an eye-witness of the great civil war, is requested by king Janamejaya to give an account of those bloody events, in which, two generations ago, his own ancestors had played a fatal part. This task, being declined by Vyâsa himself, is readily performed by one of his disciples, Vaisampâyana, who, being duly instructed, and from memory familiar with the heroic poem, recites it at full length to the listening assembly. A similar festival being afterwards celebrated by king Saunaka, the same proceedings are repeated, and Sauti, whose father had been a disciple of Vyâsa, undertakes the recital of what is now considered the original 'Bhârata.' Neither in these nor in other instances is a written copy of the text mentioned; it was in fact only committed to memory and handed down by oral tradition, until the increasing mass of subsequent episodes, more or less connected with the primitive subject, urged the necessity of a final arrangement; and, to avoid further interpolations, a summary of the contents was prefixed to the whole collection, now existing under the name of 'Mahâbhârata.' Notwithstanding the traditional character and the gradual growth of the poem, Vyâsa has been supposed not only its author, but even the operation of collecting its component parts has been attributed to him, as it was he who, according to Hindu tradition, collected the Vedâs and Purânâs, and composed the Brahmasûtras of the Vedântine school. But as these operations could not be executed by the same individual, it has long been acknowledged that the name of Vyâsa (implying *disposition*) does not signify a distinct historical person, but rather an allegorical character, including the important fact that the four great parts of the sacred canon were digested by the same orthodox body of the antient Brahminical schools, by whom almost every branch of the traditional and scientific learning of the Hindus has been successively propagated and preserved. Hence a religious and priestly character prevails in the epic poetry of the Hindus; in this sense the 'Akhyâna' is often styled a fifth 'Veda,' and the 'Râmâyana,' as well as 'Mahâbhârata,' are in fact considered as the 'Sâstra' of the Kshatriya caste, for whose recreation, encouragement, and instruction they were originally designed. Compared with the 'Râmâyana' the 'Mahâbhârata' is wanting in unity and internal coherence; it is rather a collection of antient epic poems, gathered round the central history of the Kurus and Pândus: but for this very reason it far surpasses the former poem by a greater variety of pleasing scenes and attractive situations, particularly in its episodes, the characters of which are very often delineated with so peculiar a delicacy, and with so strongly marked an individuality, as to leave a powerful impression on the reader. Finally, and what is more essential, the 'Mahâbhârata' may be looked upon as a most ample source of every kind of antiquarian lore, and as the only Sanskrit work, if we except the 'Annals of Kashmir,' by which a considerable quantity of the most valuable historical fragments has been preserved. The truth of this will be shown in a series of learned essays lately begun by Prof. Lassen (in *Zeitschrift für die Kunde des Morgenlandes*). The great war itself, which on astronomical calculations has been supposed to have taken place during the twelfth century B.C. (Works of Sir William Jones, iii., [illegible], vii., 77), is indubitably an historical event; and as Pându (white), Krishna (black), Duryodhana, Dhritarâshtra, and other names are allegorical, Prof. Lassen acutely suggests that the war might be the long and serious contest between the Brahminical tribes and the native occupants of the country. Leaving aside these questions, we only remark that although the 'Bhârata,' properly so called, is by no means contemporary with the events described in it, its pretensions to a very remote period of Hindu antiquity are sufficiently justified by internal evidence and the unanimous testimonies of subsequent writers. The poem is evidently of later date than the 'Râmâyana,' but neither the precise time in which it was composed, nor even the epoch of its finally assuming its present shape, can yet be ascertained.

Three large quarto volumes have already appeared of a complete edition in the original Sanskrit, carefully collated by learned Pundits with the best manuscripts in the library of the Sanskrit College of Calcutta, and published by the Asiatic Society of Bengal. Besides a number of detached fragments and single stories of the 'Mahâbhârata,' faithfully translated by Sir Charles Wilkins, Prof. Wilson, and Mr. Milman, such as *The Churning of the Ocean*, the *Story of Dushwanta* and *Sacuntalâ*, &c. (*Annals of Oriental Literature; Oriental Quarterly Magazine*, 1825; *Quarterly Review*, vol. xiv.), the following episodes have appeared in the original Sanskrit: 1. *Nala and Damayanti*, published by F. Bopp, Lond. 1819; Berlin, 1832. Translated into English verse by H. H. Milman, Oxford, 1835. 2. The *Bhagavadgîtâ*, by A. W. Schlegel, Bonn, 1823. An English prose translation was published by Sir Charles Wilkins, London 1785. 3. *Indralokâgamanam, Hidimbabadha, Brâhmavilâpa, Sundas and Upasunda*, and *Tilottamâ*, by Bopp, Berlin, 1824. 4. 'Diluvium cum tribus aliis Mahâbhârati præstantissimis episodiis,' by Bopp, Berlin, 1829.

MAHANADA. [HINDUSTAN, p. 216.]

MAHANUDDY. [HINDUSTAN, p. 210.]

MAHMOOD I., son of Mustapha II., was raised to the throne of the Ottomans after the deposition of his uncle Ahmed III. in 1730. He continued the war begun under his predecessor against Nadir Shah of Persia, but with no success, and made peace in 1736. A war with Russia followed, in which the Russians took Ockzakow and Kinburn in 1737, and, the Austrians having joined them, invaded Wallachia. The Austrian forces being defeated at Krotska on the Danube, the court of Vienna submitted to a disadvantageous peace in 1739, by which it gave up not only its recent conquests, but also the important town of Belgrade, the conquest of a former war. Peace was soon after made between Turkey and Russia, and the latter power restored Ockzakow. A new war broke out with Persia in 1747, and terminated by a treaty unfavourable to the Ottomans. Mahmood took little part in all these transactions, but left all the cares of state to his ministers and favourites. He died in December, 1754, of the fistula, his death being hastened by an effort which he made to ride to the mosque on a Friday, to show himself to his subjects, among whom reports of his death had been circulated. He was then fifty-eight years of age.

MAHMUD, Soboktegin of Ghisni, the founder of the Gasnevide dynasty, succeeded to the sovereignty of Chorasan and Bokhara (A.D. 997), which his father Emir Nasireddin Soboktegin had occupied under the caliphs El-Thai Billah and Kader-Billah. After having assumed the title of sultan, which was readily granted to him by the caliph, Mahmud subdued the circumjacent provinces of East Persia, made Ghisni his capital, and totally shook off the yoke of his legitimate sovereign. Bound, as he deemed himself, by the most solemn vow to adhere to the precept of the Koran, which enjoins the propagation of the Islam and war against the unbelievers as a matter of faith; or stimulated rather by ambition and covetousness, ill-concealed under the mask of religious duty, he directed his arms against the quiet and peaceful Hindus, and first attacked Jeipal, the neighbouring king of Lahore, in 1001. This expedition having proved successful, Mahmud invaded Hindustan almost every year, and in no less than fourteen subsequent incursions, made in various directions and as far as the carelessness and the feeble resistance of the Hindu rajahs would permit him to proceed, he devastated the provinces, ravaged and plundered the cities, destroyed the places of religious worship, and murdered the inhabitants, always returning with an immense booty. In the year 1016 the far-famed city of Kanoge was destroyed; and shortly after the antient and magnificent Mathura, whose palaces and temples of marble and alabaster filled even their savage conqueror with respect and religious awe. The remotest expedition of Sultan Mahmud was directed against the celebrated temple of Somnat (Somanâtha) in Guzerat (1025); and although these transitory invasions of Hindustan were only undertaken to satisfy his fanaticism and avidity, and without the intention of permanently occupying the ravaged provinces, he now almost thought of making the city of Naherwaleh his new capital. Nevertheless Mahmud retired to Chorasan, loaded with the inestimable treasures of the Indian temples. After having once more attempted a predatory excursion into Multan, he died at Ghisni, 1030, neither much lamented nor extolled by his contemporaries, whatever flattery had done during his life-time by praising his justice and equity, and softening the leading features of his character, which were cruelty and avarice. All that can be said in praise of Sultan Mahmud is, that men of learning were attracted by the fame of Ghisni, which he adorned with the most splendid buildings, and by the lustre and magnificence of his court; and the new epoch of Persian poetry, of which the Shah-Nameh is the most eminent and imperishable monument, was encouraged by the sovereign. But as the satirical poems of Ferdusi testify, even his liberality and favours were in a great degree dependent on his capricious temper, and were often bestowed in a very niggardly manner. About three miles from the modern city of Ghisni, the tomb of Mahmud is still preserved, and in remembrance of his having been a zealous defender of the faith, Mohammedan priests are maintained, who constantly read the Koran over his grave. (Mirchond, *Historia Gasnevidarum*, ed. Wilken, Berlin, 1832.)

MAHOMET I., son of Bayazid I., was sandjak, or governor, of the town and district of Amasia when his father was defeated and taken prisoner by Timur at the battle of Ancyra (July, 1401). The invader having left Asia Minor, Mahomet's elder brothers Mousa and Solyman disputed their father's succession between them. Mahomet took no part in their quarrel, but continued to administer his province, and strengthen himself in it, until Mousa, having prevailed against Solyman, put him to death, upon which Mahomet declared war against Mousa, who was defeated and killed, and Mahomet became sole sultan of the Ottomans, A.D. 1413.

Mahomet was the restorer of the Ottoman empire, which he found in a state of anarchy. He extended his conquests into Europe, and obliged the princes of Bosnia, Servia, and Wallachia to pay him tribute. He also equipped a fleet to resist the attacks of the Venetians by sea. He died, after nine years' reign, A.D. 1421. He was succeeded by his son Mourad II.

MAHOMET II., son of Mourad II., was proclaimed emperor of the Ottomans after the voluntary abdication of his father in 1444; Mourad however was obliged by a mutiny of the Janizaries, who objected to his son's youth, to resume the reins of government till his death, which happened at the beginning of 1451, when Mahomet, then twenty-two years of age, commenced his reign. He broke the truce existing with the Byzantine emperor, by building a fort on the European side of the Bosporus, opposite to the fort of Anatoli-hissar, which his predecessor Bayazid had built on the Asiatic coast of the straits, by which means Mahomet established a complete command of the Bosporus. This led to remonstrances from Constantine Palæologus, the Byzantine emperor, which were received with scorn by Mahomet, who went on subduing the Greek towns on the Propontis and the Euxine, ravaged Thrace, and invaded the Peloponnesus. At last, having assembled an immense host, stated by some at 300,000 men, with a formidable artillery, and a fleet of 120 sail, Mahomet laid siege to Constantinople in April, 1453. After fifty-four days' siege the Ottomans carried the city by storm on the 29th of May, 1453. Constantine fell bravely fighting in the breach, covered by a heap of the slain. After three days of plunder and massacre Mahomet restored order, released most of the prisoners, granted to the conquered the free exercise of their religion, and gave them the use of one half of the existing churches; the remainder, and the best of them, Santa Sophia among the rest, were transformed into mosques. Mahomet remained nearly three years at Constantinople, after which he returned in triumph to Adrianople, which was then the residence of the Ottoman sultans.

In 1456, after invading Servia, he laid siege to Belgrade, but was opposed and defeated by John Hunnyades, a gallant Hungarian noble, who was regent of the kingdom in the absence of king Ladislas. This was the first check which the Mohammedan arms encountered in their advance towards Western Europe. At the same time Mahomet's generals were defeated in the mountains of Albania by Scanderbeg. The Turks however took Corinth and the Morea. In 1461 they took Trebizond, and put an end to the dynasty of the Comnenes. In 1462 they took Lesbos and other islands of the Archipelago. They next conquered Bosnia, and Mahomet, after promising safety to the prince of that country, had him put to death. In 1465 Mahomet marched against Scanderbeg, but was defeated under the walls of Croia. But Scanderbeg lost all the open country, and dying soon after, left his infant son John Castriot under the guardianship of the Venetian senate. The Venetians attacked and plundered the coasts of Thrace, Asia Minor, and several of the Greek islands. In 1470 Mahomet laid siege to the town of Negroponte, the stronghold of the Venetians in the Ægæan Sea. The Provveditore Erizzo, after a gallant resistance, being obliged to capitulate, Mahomet promised to spare his head, but by a barbarous equivocation he had him sawed in two, saying that he had not promised to spare his sides. The Venetians by means of their commercial agents excited against Mahomet, Husun Hassan, shah of Persia, who invaded Asia Minor, and took Tocat in 1472. [Contarini, Ambrogio.] Mahomet hastened to encounter him, and a battle was fought near Trebizond, in which the Turks had the advantage over the Persians, who withdrew beyond the Euphrates.

In 1475 Mahomet took the Crimea, the khan of which became his tributary. The Turks invaded also Dalmatia and Frioul, in 1478, and advancing as far as the Tagliamento, obliged the Venetians to sue for peace, which was concluded between them and Mahomet, in January, 1479, by which Venice gave up Scutari and other fortresses in Illyria, Albania, and the Morea. In 1480 a Turkish force landed at Otranto, and spread alarm throughout Italy. In the same year the Turks attacked Rhodes, but were defeated by the Knights of St. John, under their grand-master Peter d'Aubusson. Mahomet was greatly irritated at the news of this defeat; and while he was making preparations for resuming the attack in person, he died at Teggiar Zaïr in Bithynia, in May, 1481. His remains were carried to Constantinople and interred with the following epitaph:—'I designed to conquer Rhodes and subdue proud Italy.'

Mahomet was a successful conqueror. He was cruel, like most of the Ottoman warriors; but he was not an illiterate or rude barbarian. He knew several languages, Persian, Arabic, and Greek; was fond of poetry, and was a good letter-writer. Several of his letters have been translated into Latin, and published by Landini, Lyon, 1520. Three of his letters, addressed to Scanderbeg, are found in Melchior Junius's Collection, 1595. He founded two medressés, or colleges, at Constantinople. Several stories of his cruelty, such as that against a Greek female, Irene, and the story about Bellini the painter, rest upon doubtful authority. [Bellini, Gentile.] His bad faith however is fully proved, in the instances of the unfortunate Erizzo, of the prince of Bosnia, and others. In Turkish history he is styled Mahomet the Great and the Conqueror. (Knowlles's *History of the Turks*; Mignot, *Histoire de l'Empire Ottoman*.)

MAHOMET III., succeeded Mourad III. in 1595. He began his reign by putting to death all his brothers. Giving himself up to idleness and pleasure, he left the government in the hands of his ministers, who were under the influence of his mother. His troops were beaten in Hungary by the Imperial troops, and by Battori, prince of Transylvania, and they lost Gran and other places. Mahomet, being roused from his apathy, collected a large force, with which he entered Hungary and took Agram; but he soon left the army, and hurried back to his capital. The war was carried on in Hungary by his generals, but with no success to the Ottoman arms. In the meantime revolts broke out, and the Asiatic provinces and the janizaries at Constantinople mutinied. In the midst of all these disorders Mahomet died, in 1603, and was succeeded by his son Ahmed I.

MAHOMET IV., son of Ibrahim I., succeeded his father, who was strangled in a meeting of the janizaries in 1654, when Mahomet was seven years of age. His mother assumed the regency; but a fresh revolt of the janizaries soon overthrew her power, and she also was put to death. Mahomet Kuperli, or Kupruli, was now raised to the post of grand-vizier, or prime-minister. Like many other officers who have distinguished themselves in the annals of the Ottoman empire, Kupruli was an Albanian. He and his son Achmet after him were the ruling ministers during the greater part of the reign of Mahomet IV., who troubled himself little with state affairs, being chiefly engrossed with the sports of hunting and other pastimes. The two Kuprulis spread a last ray of departing glory over the decline of the Turkish state. The elder Kupruli, after repressing by severe measures the spirit of insurrection within, formed a new fleet to oppose the Venetians, who, under the two gallant brothers Mocenigo, threatened to force the passage of the Dardanelles, in 1657. He also sent fresh troops to carry on the war in the island of Candia. Meantime the war was raging in Hungary between the Turks and the emperor Leopold I. The Turks advanced as far as Neuhausel, which they took, spreading alarm to the gates of Vienna; but they were defeated by Montécuccoli, general of the Imperial forces, at the battle of St. Gothard, 1663, after which peace was concluded. The same year Mahomet Kupruli died, and his son Achmet Kupruli became grand-vizier. In 1667 Achmet went in person to Candia, and the siege of the capital town of the same name began in real earnest. The Venetian general Morosini directed the defence. In September, 1669, Morosini, after a most gallant resistance, having exhausted all his resources, made an honourable capitulation, and at the same time concluded a treaty of peace between Venice and the Porte upon terms more favourable than might have been expected. [CANDIA.] Kupruli, unlike the barbarian Mustapha, who in the preceeding century had atrociously violated the capitulation of Famagosta [CYPRUS], faithfully kept the conditions granted to the Venetian garrison, and allowed a free passage to all the inhabitants who chose to embark.

In 1671 war broke out between the Turks and Poland, and Mahomet IV. led his army in person; but he was surprised in his camp at Budchaz by John Sobieski, grand-marshal of Poland, and the sultan was obliged to seek safety in flight. In the following year Sobieski took the fortress of Kotzim, and drove the Turks to the south of the Danube. In 1675 a formidable Turkish host, commanded by the bashaw of Damascus, who for his bravery had earned the name of 'Shaitan' (the devil), entered Poland. Sobieski, who was then king, resisted all their efforts with a handful of men, and at last obliged them to ask for peace, which was concluded in 1676.

In 1683 the Turks, after seven years' preparation, put into motion the most formidable army which Europe had seen for a long time. They swept over Hungary like a storm, and marched direct upon Vienna. It is generally admitted that Louis XIV. was privy to their plans. The emperor Leopold and his family left their capital, and Germany and Italy were thrown into consternation. On the 15th of July Vienna was invested by the grand-vizier Kara Mustapha (Kupruli was dead), at the head of 300,000 men, Turks and Tartars. On the morning of the 11th September Sobieski and Charles duke of Lorraine, at the head of their combined forces, 40,000 strong, reached the summit of the Calemberg, from which they beheld the Austrian capital and the wide-spread glittering tents of the Ottomans. On the following day Sobieski attacked and drove the Turks to their formidable entrenchments, against which, at five o'clock in the afternoon, he led a general assault, carried everything before him, and obliged the vizier to fly after making a gallant resistance, leaving his camp, his baggage, and his artillery in the hands of the Christians. The Turks subsequently lost Hungary. In consequence of these disasters the janizaries at Constantinople revolted in 1687, Mahomet IV. was deposed, and Solyman III. was raised to the throne. Mahomet died in confinement in 1691.

MAHOMETANISM. [MOHAMMEDANISM.]

MAHON, PORT. [MINORCA.]

MAHRATTA LANGUAGE. [HINDUSTAN, p. 227.]

MAHRATTAS, or MAHARATTAS. The origin of these people, whose wars have filled so large a space in the history of British India, is involved in much obscurity. The country possessed by them before the modern invasion of India by Europeans is supposed to have included Candeish, Boglana, part of Berar, extending to the north-west as far as Guzerat and the river Nerbuddah, and a tract of country on the west coast lying between Surat and Canara. A great part of these countries consists of mountains and defiles, which offer great natural facilities for the prosecution of predatory and of defensive warfare. It is supposed that the name Mahratta was derived from Mheerut, or Mharat, a district which under the sovereigns of the Deccan formed part of the province of Dowlutabad. The earliest mention that we find of the Mahratta tribes is in 1306, when Cafoor, a slave and general of Alla, is said to have 'subdued the country of the Maharattas, which he divided among his Omrahs.' The Mahratta empire, as it takes a place in modern history, was founded in the latter half of the seventeenth century, in the reign of Aurungzebe, by Sevajee, the son of Shahjee, a Hindu in the service of the king of Bejapore, from whom he received a jaghire in the Carnatic, with the command of 10,000 cavalry. His first act was the seizure of the Zamindary of Poonah, on which occasion he increased the number of his soldiers, and levied contributions in all the neighbouring districts. Sevajee died in 1680, and was succeeded by his son Sambajee, a man of considerable talent, but who was unable to withstand the power of Aurungzebe, and, falling into his hands, was cruelly put to death in 1689. His son Sahoo Raja, who had also fallen into the hands of the emperor, reigned in name only until 1740, when he died; but at the death of Sambajee a great number of chiefs, availing themselves of the natural facilities offered by the country, issued from various points in the mountains, and kept up a constant predatory warfare in the neighbouring provinces, plundering and devastating wherever they penetrated. The wealth thus acquired by them caused them to be joined by vast numbers of adventurers, as well as by many Zamindars, and after a long struggle for their subjection, they were, at the death of Aurungzebe in 1707, more powerful than ever. From the death of Sambajee in 1689 till the year 1818, the nominal sovereign or raja of the Mahrattas had no real power, but was a prisoner, confined in the hill-fortress of Satara, while the government was administered by the Peshwa, or minister, whose office became hereditary in the family of Balajee Bishenauth, its first possessor, who fixed his residence at Poonah. He was succeeded by his son Balajee Bajerow, who died in 1761. The next Peshwa was Madhoo Rao, who filled the office for 11 years, and dying was succeeded by his son Narrain Rao. This chief was murdered in 1773, concerning which event very different statements are given. By one it is said that the murder was committed by his uncle Ragoba with the design of usurping his office, but that the usurpation was prevented by twelve chiefs, at the head of whom was Balajee Pundit, better known as Nana Furnavese, who set up Sevajee Madhoo Rao, the posthumous son of Narrain, and administered the government during the minority. Mill (*History of British India*, vol. ii., p. [illegible]) gives a very different version; he states that the murder was committed by the chiefs before mentioned, that the fact of Sevajee Madhoo Rao being the son of Narrain was disputed, and that Ragoba, whose right to the succession was perfect, fled to Guzerat, where he obtained the promise of support from the Guicowar. For some time preceding these events the English government had desired the possession of Salsette and Bassein, then forming part of the possessions of the Mahratta government; and this appearing a favourable opportunity, they formed a treaty with Ragoba, engaging to replace him in his office, and they took possession of Salsette and Bassein, much against the will however of Ragoba, who offered other territory and revenue to a larger amount as the price of British assistance. Upon his giving way on this point, an English force of 25,000 men was put in motion in his favour. Negotiations had at the same time been opened with the authorities at Poonah, who yielding to the cupidity of the English government concerning Salsette and Bassein, the latter was induced to withdraw all active assistance from Ragoba, who retired to Surat with only 200 attendants. Sevajee Madhoo Rao died in consequence of an accidental fall in 1795, and after some considerable dissensions his son Bajerow was declared Peshwa. The latter continued in power until October, 1802, when his forces being totally defeated near Poona by Jeswunt Rao Holkar, he fled to Bassein and placed himself under the protection of the British government. In the following year he was reinstated in his capital by General Wellesley (now the duke of Wellington). Bajerow proved to be of an intriguing disposition and very avaricious. He permitted his officers to practise all manner of extortion, but brought in the end, seizing their ill-gotten treasure. In 1817 he was detected in the endeavour to form a general confederacy against the English; his capital was in consequence surrounded, and he was forced to cede in perpetuity districts yielding a revenue of 340,000*l.* and to make a temporary surrender of Singhur, Poorunder, and Ryeghur, as pledges for the fulfilment of existing treaties. In November, 1817, the Peshwa, in defiance of all engagements, suddenly attacked and destroyed, having first plundered, the houses of the British residency near Poonah. This treacherous conduct was speedily punished; his forces were on the following day routed by the English troops, and he became a fugitive, and wandered about in various directions until June, 1818, when he surrendered himself to Sir John Malcolm, and renounced all sovereignty for himself and his family, upon the promise of an adequate pension. On this occasion the greater part of the Peishwa's territory, estimated at 50,000 square miles, came into possession of the English.

In the early period of Mahratta history the custom prevailed of the nominal head of the people conferring large grants of land on the principal chiefs, and of delegating to them extensive powers of government. These chiefs, one by one, assumed the state and attributes of princes, but with still that attachment to ancient forms and that respect for hereditary power for which the Mahrattas have always been remarkable, they acknowledged the supremacy of the nominal head of the state, but either submitted to or evaded his authority as best suited their interest at the moment.

MAIA. [MAIIDÆ.]

MAIDEN HAIR, the common name of the Adiantum Capillus Veneris, a fern found wild in many parts of Europe, on damp shaded rocks. It is the *adiantum* (ἀδίαντον) of the Greeks, and has probably gained its trivial name from its having formed a part of the preparations used by ladies for softening their hair. (Dioscorides, l. iv., c. 136.)

MAIDSTONE, a corporate town and parliamentary borough, in the parish and hundred of Maidstone and county of Kent, of which it is the county and assize town. Maidstone is situated on a pleasant declivity chiefly on the right bank of the Medway, about two miles above Allington lock, eight miles above Rochester, and 32 miles south-east by east from London. Till the lock was constructed on the river the tide came up to Maidstone. It consists of four principal streets, which are well paved and lighted, and it contains many well-built houses. There are two reservoirs for supplying the inhabitants with water, conveyed from a spring on the opposite banks of the Medway, which river is here crossed by a very ancient stone bridge of several arches. The derivation of the name 'Maidstone' is not precisely known; at least, various etymologies are given by Camden, Hasted, and others. According to Nennius (*Catalogue of the Cities of Britain*), this place was called by the British Caer Medwag, or *Medwag*, signifying the town or city of the Medway. At a very early period Maidstone formed part of the possessions of the see of Canterbury, and is entered in the general survey of Domesday under the title of the lands of the archbishop. The charters of incorporation are those of 3 Edward VI., 2 Elizabeth, 2 and 17 James I., 34 Charles II., and 21 Geo. II. The first of these was forfeited in the reign of Queen Mary, in consequence of the supposed participation of the leading members of the corporation in the rebellion of Sir Thomas Wyatt.

The revenue of the corporation in 1833, arising from landed property, tolls, &c., was estimated at 1114*l.* The bond debt at that time was 15,875*l.*, and the annual expenditure, the chief item in which was the interest on this debt, was supposed to be about equal to the income. Since the establishment of the police under the Municipal Corporation Act the expenditure has been considerably increased. The landed property has lately been sold, and a great part of the debt paid off. The town is divided into six wards; the town-council consists of 6 aldermen and 18 councillors.

The town is said to be in a thriving state. There are manufactures of felt and blankets, but these are of limited extent compared with the paper-mills, which employ upwards of 800 hands. The traffic up and down the river is considerable, and has been materially increased by the construction of the lock for improving the navigation. The imports consist chiefly of coal, timber, groceries, iron, and rags; the exports are mostly fruit, hops, stone from the quarries of Kentish ragstone in this parish and neighbourhood, and paper. The aggregate tonnage of the vessels passing through Allington lock is estimated at 120,000 tons, upon which tolls to the amount of 2000*l.* are annually collected.

There is no borough gaol: the justices of the borough commit all prisoners to the county gaol, and the expense of their maintenance, amounting to one shilling per day for each prisoner, is defrayed out of the borough-rate. On the east side of the river there are cavalry barracks. Nearly opposite to the town-hall is a spacious commercial room used as a Corn Exchange. The archbishop's palace is a Gothic structure, rebuilt about the middle of the fourteenth century. Since that time it has undergone considerable alteration, and in its present state is a pleasant and convenient residence. The chapel of Newark Hospital, which was built in the thirteenth century, is a small but beautiful specimen of the early pointed style. Maidstone formerly contained a college, consisting of a master, sub-master, and four priests, founded by Archbishop Courtenay in the reign of Richard II. It was suppressed by Edward VI., at which time its nett annual revenue was 159*l.* 7*s.* 10*d.* Among the persons of literary eminence who were connected with this college was the learned William Grocyn, the friend of Erasmus. He died in 1522, and was interred at Maidstone. (Wood's *Athenæ Oxon.*) There was also a fraternity of Corpus Christi, and upon the suppression of this fraternity the buildings belonging to it, then called 'The Brotherhood Hall,' were purchased by the corporation, who established the free grammar-school, which still exists, but is not at present in a very flourishing condition. Freemen have the privilege of sending their sons to this school, where they receive a classical education gratuitously, but for other branches a charge is made by the master, who receives a salary of 23*l.* 12*s.* per annum from the funds of the corporation, and has the management of certain lands in Romney Marsh confided to him, these lands constituting the principal endowments of the school. There are exhibitions, founded by Robert Gunsley in 1618, for four scholars to University College, Oxford; two to be elected from this school, and two from the free grammar-school of Rochester. Besides the grammar-school there are a proprietary school, four charity schools, nineteen almshouses, a medical dispensary, and other benevolent institutions. Maidstone is in the diocese of Canterbury. The living is a perpetual curacy in the patronage of the archbishop, producing a net income of 720*l.* The parish church of All Saints, which is one of the largest in the kingdom, was built in the fourteenth century; the new church was built a few years ago. There are also nine places of worship for Dissenters. The population of the borough, which is coextensive with the parish, was 15,387 in the year 1831, exclusive of the prisoners confined in the county gaol, and is still increasing. The assessed taxes collected during the preceding year amounted to 4764*l.* Maidstone has returned two members to parliament continuously from the reign of Edward VI. The county gaol at Maidstone is a modern building, constructed in 1818 on the improved radiating plan, at an expense of 200,000*l.* According to the Gaol Returns transmitted to the secretary of state it appears that in the year 1834 the general state of the prisoners as to morals, discipline, employment, &c., was eminently satisfactory. The total number then confined was 463; the gaol is capable of containing 453 in separate sleeping cells. The hours of labour are from six in the morning to half past five in the evening, when the daylight admits; and at other times of the year from daylight in the morning till half an hour before sunset in the evening. By means of Sunday and day schools, conducted under the direction of the chaplain, provision is made for the instruction of prisoners of all classes. (*Parliamentary Papers*, 1834, vol. XLVI.)

There are four fairs held annually on the 13th of February, 12th of May, 20th of June, and 17th of October; the last is a large hop-fair.

(*Corporation, Boundary, and Church Revenue Reports*; Hasted's *History of Kent*; *Beauties of England*; Camden's *Brit.* &c.)

MAIIDÆ, or **MAIANS**, the second tribe of the family of *Oxyrhynchi*, according to the system of M. Milne Edwards, composed of brachyurous crustaceans, whose *carapace*, nearly always very spiny, is, with some exceptions, much longer than it is wide. *Rostrum* generally formed of two elongated horns. First joint of the internal antennæ but little developed; that of the external antennæ, on the contrary, very large, and soldered with the neighbouring parts so as to be confluent with them; its external border always constituting a considerable portion of the lower wall of the orbit, and its anterior extremity united to the front before the level of the internal canthus of the eyes. The moveable stem of the antennæ always of considerable length. The *epistome* generally considerably wider than it is long, whilst the *buccal frame* is longer than it is wide. The third joint of the external *jaw-feet* is as wide as it is long, more or less dilated on the external side, and truncated or notched at its anterior and internal angle, by which it is articulated with the fourth joint, which is very small. The anterior *feet* of the female are in general hardly larger or longer than the others, and sometimes they are even shorter. The same conformation obtains in some of the males; but in general the first pair of feet in these last are longer and much larger than the second pair, and their length sometimes is equal to twice that of the carapace. they are directed obliquely forwards and outwards; the hand is never triangular, and the immoveable finger of the claw is not inclined downwards, so as to form a decided angle with the lower edge of the hand. The succeeding feet are generally of moderate length; those of the second pair are most commonly once and a half the length of the post-frontal portion of the carapace, but they are never twice as long as that portion; those of the third pair are hardly ever more than once and a quarter as long as the post-frontal portion of the carapace, and the other feet shorten in succession. The *abdomen* is ordinarily composed of seven distinct joints in both sexes; but sometimes this number varies in the different species of the same genus. (M. Edwards.)

Genera. Libinia. (Leach.)

This genus has the greatest relation to *Doclea* and *Pisa*, between which genera it establishes, in the opinion of M. Milne Edwards, a nearly insensible passage. The general form of the body in *Libinia* approximates closely to that of *Doclea*.

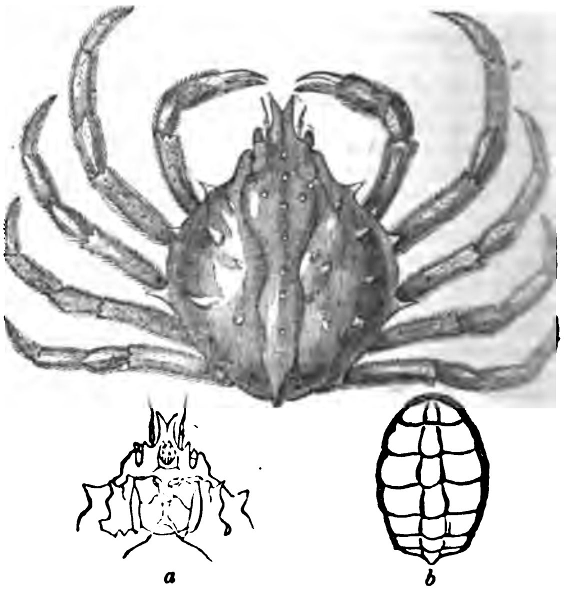
Generic Character.—Carapace very convex above, in general nearly circular, with its orbito-frontal portion placed sensibly above the level of its lateral borders, which are prolonged towards the mouth rather that towards the external canthus of the eyes. Sometimes the carapace is elongated a little, and bears a considerable resemblance to that of some of the *Pisæ*. *Rostrum* small, narrow, and notched in the middle; the *front*, measured between the orbits, is much narrower than the anterior extremity of the buccal frame; the anterior angle of the superior orbital border is projecting, but never reaches beyond the basilary joint of the external antennæ; the *orbits* are nearly circular, and directed very obliquely forwards and outwards; their external angle is formed by a large compressed tooth, which is separated from the rest of the wall of this cavity by two fissures; one superior and very narrow, the other inferior and more or less open. The stomachal region of the *carapace* is but little developed, but the branchial regions highly so, and their lateral border, which is armed with spines and very much curved, is directed towards the anterior angle of the mouth. The eyes are small and very short; the basilary joint of the external *antennæ* is short, but very much developed, and always wide in front, a disposition which occurs in *Pisa*, whilst the contrary is to be remarked in *Doclea;* the second joint of these antennæ is stout, short, cylindrical, and inserted on the sides of the rostrum at a distance nearly equal from the orbit and the antennary *fossette;* the third joint is rather smaller than the second, and the fourth is very slender and very short. The *epistome* is very small, and the whole of the *antennary region* is not more than half the length of the buccal frame. The external jaw-feet and the *sternal plastron* have the same form as in *Pisa*. The anterior feet are much longer than in *Doclea*, but less developed than in *Pisa;* they are always nearly of the same size as those of the second pair, and in general are much shorter even in the males; the hand is very nearly cylindrical, and has little convexity; the pincers are rounded or trenchant, and finely dentilated, and touch nearly throughout their length, a disposition which is rare in the *Pisæ*. The remaining feet much resemble those of the *Pisæ*, except that their last joint is longer, and never armed below with horny spines, as in them; the length of the feet diminishes progressively, and those of the second pair are not more than about once and a half as long as the post-frontal portion of the carapace; they are in general much shorter, and this character suffices to distinguish the *Libiniæ* from the *Docleæ*. The *abdomen* is composed of seven joints in each of the sexes.

Geographical Distribution of the Genus.—The seas of America, as far as is known.

M. Milne Edwards divides the genus into two sections; the first consisting of species which have the anterior and external angle of the basilary joint of the external antennæ obtuse, and not prolonged beyond the level of the internal one, and the slit of the inferior orbital border very narrow; the second consisting of species which have the anterior and external angle of the basilary joint of the external antennæ spiniform, and prolonged much beyond the level of the internal angle, and the slit of the inferior orbital border very wide.

Our limits will not permit us to give more than one example, and we select *Libinia spinosa*, a species belonging to the second section. The body is entirely covered with a short and brownish down, and it is about four inches (French) in length.

Locality.—The coasts of Brazil.



Libinia spinosa.

a, under side of head in detail; *b*, abdomen of female.

Herbstia. (Milne Edwards.)

Intermediate between the *Libiniæ*, the *Pisæ*, and the triangular *Mithraces*.

Generic Character.—Carapace more triangular than in *Libinia;* the stomachal region nearly as much developed as the branchial regions. *Rostrum* small, hardly longer than it is wide, and formed of two flattened horns, which are pointed and divergent, and the base of which occupies all the width of the front. *Orbits* oval-shaped, and directed obliquely forwards, outwards, and upwards; their superior border with two small fissures, which terminate anteriorly in a small spine, less projecting than that situated behind and belonging to the basilary joint of the external antennæ; their inferior border is complete, and presents only a small fissure. *Eyes* large and retractile. Disposition of the antennary region, the *jaw-feet*, the *sternal plastron*, and the *feet*, essentially the same as in *Pisa*. The tarsi of the four last feet present small horny spines placed irregularly

The only species known, *Herostia condyliata*, has the body covered with a thin and fine down, is about two inches in length, and of a reddish colour

Locality.—The Mediterranean

[illegible]

Pisa. (Leach.)

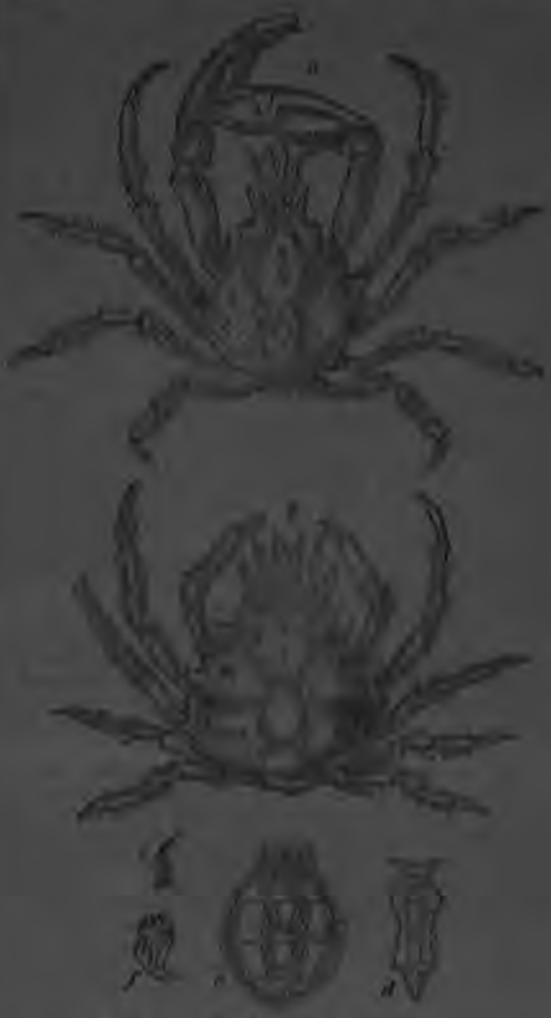
Generic Character.—*Carapace* gradually narrowed anteriorly for about three-fourths, and its latero-anterior borders prolonged obliquely in a nearly straight line up to a small distance from its posterior border; the surface very convex; the regions in general sufficiently distinct, and the stomachal region in particular very much developed. The front wider than the buccal frame, and armed with four horns directed forwards, the two external of which occupy the anterior extremity of the superior orbital border, and the two middle of which form the *rostrum*, which is always at least once and a half as long as it is wide. *Eyes* carried on very short peduncles, and bent backwards in the orbits, which are of an oval shape, and directed outwards and forwards; the upper border of these cavities with two fissures separated from each other by a triangular tooth, and their external angle situated rather below than above the lateral border of the carapace, which is there terminated. The orbital border interrupted below by a large notch. The internal *antennae* without any peculiarity. The basilar joint of the external antennae much longer than it is wide, only slightly narrowed forwards, and exceeding the level of the internal canthus of the eyes, but completely hidden above by the spiniform prolongation of the superior orbital border. The second joint of the antennae slender and cylindrical, and inserted at a distance nearly equal from the antennary fosset and the orbit, a little without the level of the external border of the rostrum, so as to show itself between this prolongation and the lateral horn of the front. The third joint small and cylindrical, and the fourth rather long. *Antennary region* nearly of the size of the buccal frame, and the *epistome* large and nearly square. The second joint of the external *jaw-feet* prolonged from the internal side much beyond the level of its external border; and the third joint much longer than it is wide, strongly dilated outwards, and deeply notched at its anterior and internal angle. *Sternal plastron* longer than it is wide. In the female the anterior feet are in general nearly of the same length as those of the second pair; but in the male they are remarkably longer and stouter; the hand is convex, and the fingers trenchant and finely denticulated on their internal margin. The remaining feet are cylindrical, and of moderate length; those of the second pair are not much longer than the post-frontal portion of the carapace; the length of the other feet diminish successively, and, in nearly all the species, their last joint is furnished below with small horny points, which are placed very regularly on one or two longitudinal lines, like the teeth of a comb. *Abdomen* composed of seven distinct joints.

The whole of the body of the *Pisae* is ordinarily covered with hairs, which are recurved at the ends, and catch up various bodies which they touch; it is not rare therefore to see these crustaceans covered with sea-weeds and sponges. The hairs of these probably answer the double purpose of enabling them to surprise their prey, and of protecting them from their enemies.

Geographical Distribution of the Genus.—Nearly all the species live in the European Seas at considerable depths, and are often dredged up by the fishermen. Some species, however, are frequently found hidden under stones at low water. They are not used as food.

The species are divided into two sections, depending on the absence or presence of spiniform teeth on the upper border of the third, or third and fourth joints of the four last pairs of feet, &c. The first of these sections is separated into two subdivisions, depending principally upon the rounded or triangular form of the posterior portion of the carapace. We select as an example one of the species of the first subdivision of the first section, *Pisa tetraodon*. This species is two or three inches in length, and has the body entirely covered with a kind of down and some recurved hairs; it is of a brownish colour.

Locality.—Very common on the English and French coasts.



Pisa tetraodon.

a, male; b, female; c, abdomen of female; d, abdomen of male; e, external f, [illegible]

Lissa. (Leach.)

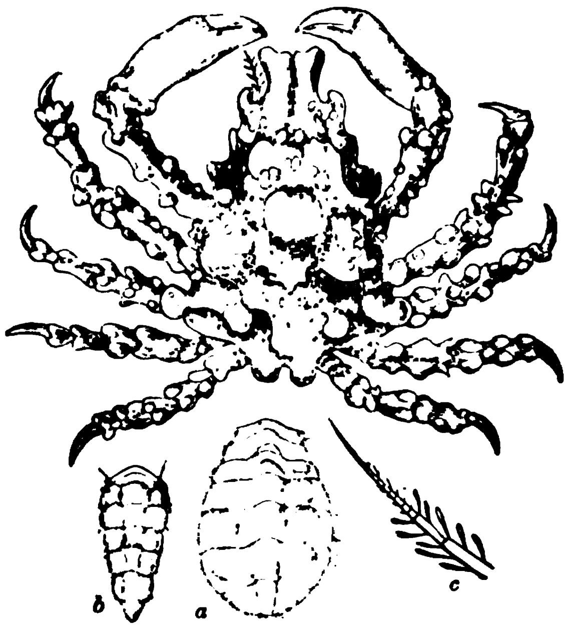
Very much resembling *Pisa*, and perhaps ought not to have been separated from it. The distinguishing characters of *Lissa* consist in the disposition of the *rostrum*, which is formed of two lamellar horns, truncated anteriorly, and wider anteriorly than they are at their base, and in the absence of spines on the tarsi. One species only, *Lissa chiragra*, is known; its length is about two inches, and the colour an intense red. The feet are furnished with some hairs, but the trunk is unarmed.

Locality.—The Mediterranean. Dr. Leach states that it is said to have been taken also on the coast of Cornwall by Mr. Swainson.

M. Milne Edwards remarks that *Lissa fissirostris* of Mr. Say seems to bear much analogy to *Hyas Araneus*; but M. Edwards cannot be certain that it belongs to the same genus from the author's description.

Hyas. (Leach.)

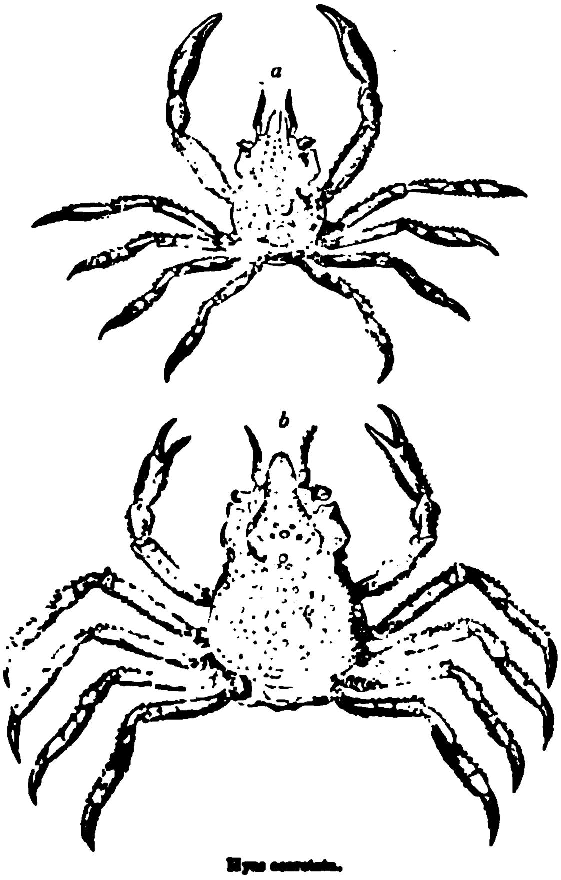
Approaching very nearly to *Pisa* and especially to *Herbstia*, but easily distinguished by the form of the first joint of the *external antennae*, which, instead of being cylindrical, as in nearly all the Oxyrhynchi, is flattened and enlarged



Lissa chiragra.

a, abdomen of female; b, abdomen of male; c, antenna.

on the external side. *Carapace* rather large, especially anteriorly; *rostrum*, which is formed of triangular horns that are flattened and convergent, moderate, and leaving the insertion of the moveable stem of the external antennæ completely visible; *front* large; *orbits* directed a little forwards; edges not spiny, and with a single fissure above. External edge of the basilary joint of the antennæ straight, and separated from the external portion of the orbit by a very large notch. The third joint of the *external jaw-feet* a little dilated outwards. *Feet* disposed as in *Pisa*, except that the four last pairs are longer, and have no spines on the inferior surface of the tarsus.



Hyas coarctata.

a, male; b, female.

Example, *Hyas coarctata*, Leach. The carapace of this species is strongly contracted beneath the external orbital angles. Length about two inches; colour yellowish.

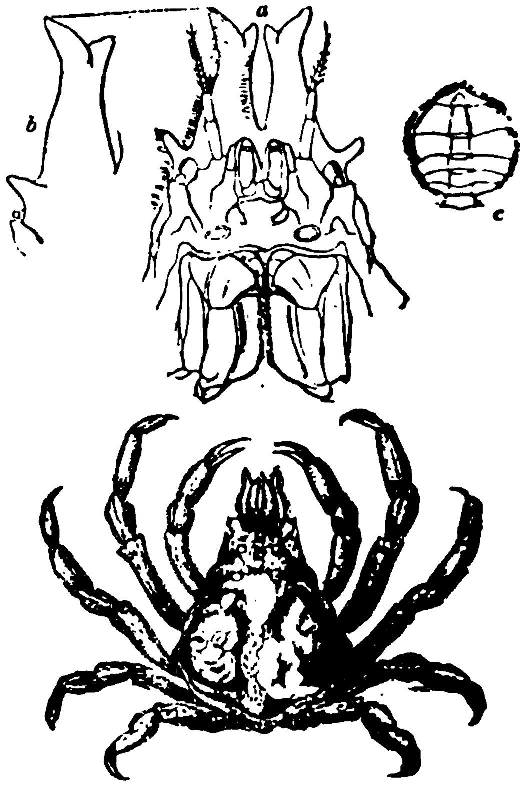
Locality.—English Channel.

Naxia. (Milne Edwards.)

Establishing, in the opinion of M. Milne Edwards, the passage between the genera *Lissa* and *Chorinus* of Leach. General form of the body as in *Pisa* and *Lissa*, and the disposition of the *rostrum* very analogous with that which is proper to *Lissa*. *Naxia* is however distinguished from the preceding genera by the disposition of the antennæ and orbits. *Carapace* nearly pear-shaped, *rostrum* much resembling that of *Lissa*. *Orbits* very small, nearly circular, deep, and marked with a fissure above and below, but without any hiatus at their inferior border. Basilary joint of the external antennæ wide but narrow forwards, very much advanced, and completely hidden by the rostrum and the anterior angle of the superior orbital border; the moveable stem of these appendages inserted under the rostrum, near the antennary fosset, and not beyond the edge of the external border of that prolongation, as in *Pisa*. *Eyes* very large.

Example, *Naxia serpulifera*, *Pisa serpulifera*, Edwards. Length about four inches; body covered with a brown down, and the carapace often incrusted with *flustræ*, *serpulæ*, *sponges*, and the like.

Locality.—New Holland.



Naxia serpulifera, one-third its nat. size.

a, under side of the head in detail; b, one of the protruding points, [illegible] eye in profile; c, abdomen of the female.

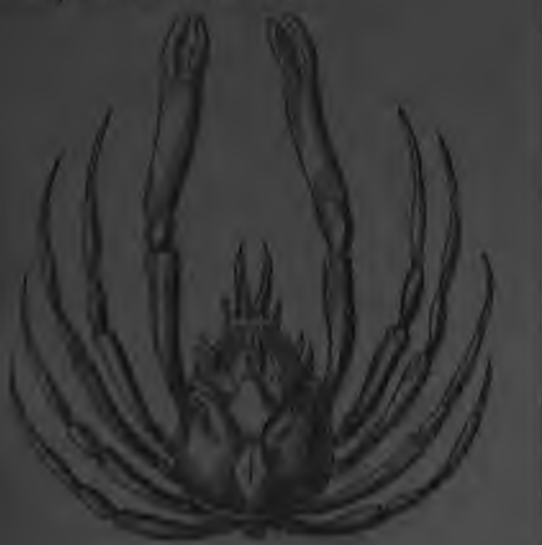
Chorinus. (Leach.)

Carapace longer and narrower than it is in nearly all the Maians; but, in general form, not differing much from *Pisa*. *Rostrum* formed of two great pointed [illegible] horns. *Eyes* retractile, and the *orbits* directed outwards and downwards; but the lower wall of those cavities is very incomplete. Basilary joint of the external *antennæ* narrow; their moveable stem inserted under the *rostrum*, and, in great part, concealed by it. *Epistome*, *jaw-feet*, *sternal plastron*, and abdomen, disposed nearly as in *Pisa*. Anterior feet longest, especially in the males, and the claws are curved inwards, dentilated and pointed, but a little hollowed out into a sort of gutter. The succeeding feet are cylindrical; those of the three last pairs of moderate length, and the second pair are very long: in the male they are in general more than a half or even twice as long as those of the third pair.

M. Milne Edwards divides the species of this genus into two sections: the 1st, consisting of those which have the superior orbital border scarcely notched, and armed by three spines, the anterior one very large, and the two posterior rudimentary; the 2nd consisting of those species which have the superior border lamelliform and advanced.

We select as an example *Chorinus Heros*, the only species of the first section. Length from two to three inches or rather more; rostrum, sides of the carapace, and four last pair of feet hairy; colour yellowish red.

Locality.—The seas of the Antilles.



Chorinus Heros (reduced one-half).

Mithrax. (Leach.)

Carapace always a little convex above, and a good deal narrowed forwards; disposition of the different regions as in the other Oxyrhynchs. *Rostrum* bifid, generally very short, and separated from the internal canthus of the eyes by a rather considerable space; orbits nearly always armed with two or three spines at their superior border, one at their external angle, and one or two at their inferior border. Latero-anterior borders of the carapace spiny, or at least toothed. Internal *antennæ* bent a little obliquely outwards, and the frontal portion of the partition which separates them armed with a recurved spine. Basilary joint of the external antennæ large, and nearly always armed forwards with two strong spines. The second joint of these appendages is, on the contrary, narrow and cylindrical, and inserted on the sides of the rostrum nearer the antennary fosset than the orbit; third joint nearly as large and as long as the second; the terminal and articulated stem rather short. External *jaw-feet* presenting nothing remarkable; *sternal plastron* nearly circular. Anterior *feet* generally, in the male, longer and stouter than that of the second pair, the hand or claw always short and convex, the pincers distant at their base, enlarged at the end, deeply hollowed into a spoon-shape, and terminated by a semicircular trenchant edge. *Feet* of the second pair about once and a quarter as long as the post-frontal portion of the carapace; the succeeding feet gradually shortened; the tarsi short, hooked, and often armed with some points at their inferior surface. *Abdomen* generally formed of seven joints in both sexes; but sometimes only four are to be perceived in young females, the second, third, fourth, and fifth segments being soldered.

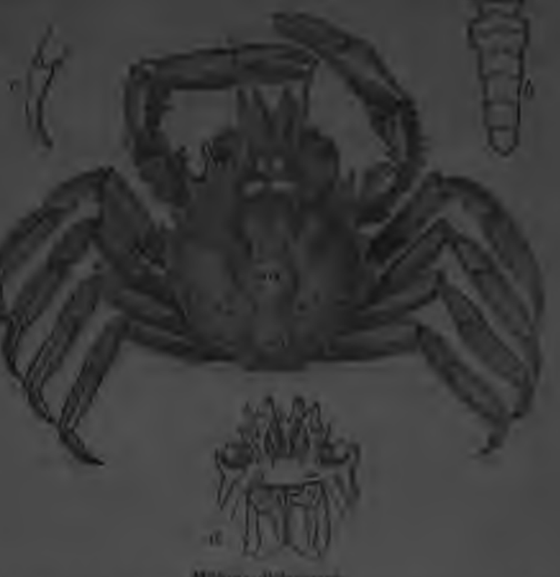
M. Milne Edwards remarks that *Mithrax* establishes a true transition between the family of the Oxyrhynchs and that of the Cyclometopes.

Geographical Distribution of the Genus.—The seas of America are for the most part, where some of the species attain to a considerable size.

M. Milne Edwards divides the genus into two sections:—the first, consisting of those species which have the superior [illegible] orbit armed with strong spines; the second, of those whose [illegible] of the orbit unarmed.

The first of these sections is further subdivided into two subgenera, the first subgenus consisting of those *triangular* species whose four last feet are not spiny; and the second subgenus, of those *transversal* species whose four last feet are armed with spines. The second section contains the third subgenus, consisting of the *depressed* species.

We select, as an example, a species illustrative of the first subgenus, *Mithrax dichotomus*. Size, about two inches; colour yellowish. *Locality.*—Coasts of the Balearic Islands.



Mithrax dichotomus.

a, under part of the head; *b*, abdomen of the male; *c*, extremity of one of the posterior feet.

Paramithrax. (Milne Edwards.)

Establishing, in the opinion of M. Milne Edwards, the passage between *Mithrax* and *Maia*.

General form of the *carapace* very closely approaching that of the triangular *Mithraces*. *Rostrum* formed of two stout horns, and considerably less wide than the front, which, in its turn, has nearly as much extent as the buccal frame. *Orbits* oval-shaped, their upper border arched forwards as in the *Maiæ*, and with three strong spines posteriorly separated by two notches more or less deep; their inferior border widely notched or incomplete. *Eyes* retractile, with slender peduncles, which are rather long and curved, as in the *Maiæ*. The antennary region and antennary pits resembling those of the *Maiæ*. Basilary joint of the external antennæ large and armed with spines, one of which (the external) advances in general beyond the border of the front, and separates the orbit from the insertion of the moveable stem, which is not covered by the front. *External jaw-feet* and *sternum* nearly as in the *Maiæ*. Anterior feet of moderate strength, and terminated by pointed and rounded claws, which are not denticulated as in *Pisa*, nor hollowed into a spoon-shape as in *Mithrax*. The succeeding feet are cylindrical, very little or not at all spiny, and of variable length, according to the species; there are no small horny points at the lower end of the last joint, as in most of the *Mithraces*.

Geographical Distribution of the Genus.—Australasia.

M. Milne Edwards divides *Paramithrax* into two sections:—the first consisting of those species which have the orbits very incomplete below, and whose eyes do not reach to the external angle of the cavities; the second, of those whose orbits have only one notch below, and whose eyes, when turned back, touch the external orbital angle. *Paramithrax Peronii* is an example of the first section, and *P. Gaimardii* of the second.

Maia. (Lamarck.)

This genus was established by the author of the 'Animaux sans Vertèbres,' for the reception of the genera *Inachus* and *Parthenope* of Fabricius, or, in other words, for all the Oxyrhynchs properly so called. More modern authors have cut the Lamarckian genus down to the group formed by the small number of species which may be arranged in close approximation to *Maia Squinado*.

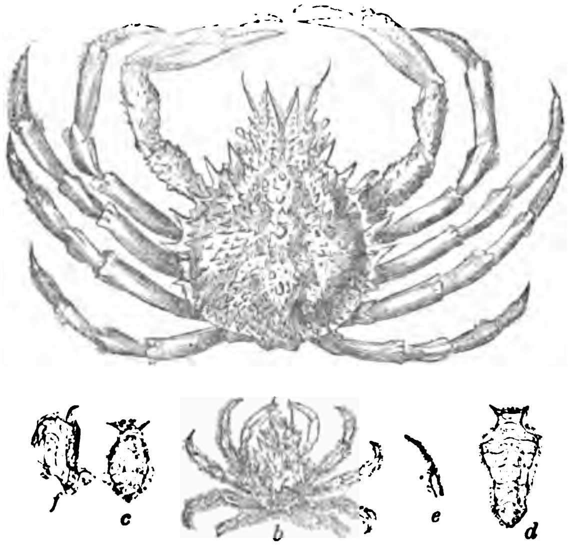
Carapace about a fourth longer than it is wide, and much narrowed anteriorly; its upper surface is rough, with multitudinous tubercles and spines, and the regions are not strongly marked on it; *rostrum* horizontal, and formed of two divergent horns; the latero-anterior border of the carapace armed with strong spines; *orbits* of an oval shape, rather deep, and with their superior border, which is elevated and rounded anteriorly, divided behind by two fissures. Internal *antennæ* exhibiting nothing remarkable, but the portion of the front which separates their fossets or pits is prolonged into a strong curved spine, which is directed downwards. First joint of the external antennæ very large, and constituting more than half of the inferior floor of the orbit, which it only exceeds anteriorly a very little; its extremity is armed with two stout spines, and carries the succeeding joint at its superior and external border, so that the moveable stem of these appendages springs in the internal canthus of the eyes. *Epistome* wider than it is long; *buccal frame* the same. Second joint of the *external jaw-feet* prolonged a good deal, from the internal side. *Sternal plastron* nearly circular, and its median suture, although sufficiently long, only occupying the last thoracic ring. First pair of feet not a great deal shorter than the others, slender, nearly cylindrical, and terminated by a claw, the fingers of which, nearly styliform, are never hollowed into a spoon-shape nor dilated towards the extremity, and present few or no dentilations. Length of the second pair hardly exceeding once and a half the width of the *carapace;* the succeeding feet gradually shorter; their terminating joint is styliform, and presents neither spines nor dentilations on its inferior border. *Abdomen* consisting of seven distinct joints in both sexes.

Geographical Distribution of the Genus.—The seas of Europe.

Example, *Maia Squinado.* Body covered with hooked hairs; length four or five inches; colour reddish.

Locality.—The British Channel, the oceanic coasts of Europe, and the Mediterranean.

This species is often dredged up, and the fishermen sometimes eat it, but its flesh is not much esteemed. It was considered by the antients to be endued with reason, and was by them represented suspended from the neek of Diana of the Ephesians, as an emblem of wisdom. It is also figured on ancient coins and medals.



Maia Squinado (reduced).

b, female, young; *c*, abdomen of female; *d*, abdomen of male; *e*, antenna; *f*, pedipalp.

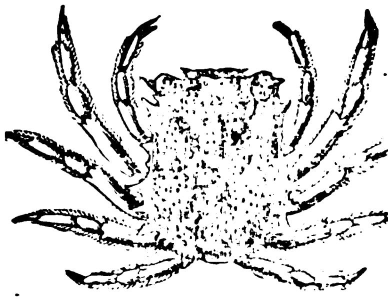
Micippa. (Leach.)

Post-frontal portion of the *carapace* nearly quadrilateral, slightly convex, rounded backwards, and hardly narrowed anteriorly; its fronto-orbital border is straight and very wide, and its lateral borders are armed with spines. *Rostrum* lamellar, and directed vertically downwards so as to form a straight angle with the axis of the body and the epistome. Orbits placed above and on the sides of the rostrum; at their superior border a deep slit; *ocular peduncles* retractile, rather long, narrowed in the middle and prolonged to the extremity of the cornea. The stem of the internal antennæ in bending back remains vertical, instead of becoming horizontal, as in nearly all the other brachyurous crustaceans. The basilary joint of the *external antennæ* very large, and wider in front than it is behind; the second joint of these appendages is inserted against the edge of the rostrum, at a considerable distance from the orbit. The third joint of the *external jaw-feet* is extremely dilated on the external side, and very deeply notched at the point where it articulates with the succeeding piece. *Sternal plastron* nearly circular. *Feet* cylindrical and of moderate length, there being little difference in size and length between the first and succeeding pairs. *Abdomen* consisting of seven distinct joints in both sexes.

Geographical Distribution of the Genus.—The coasts of the Indian Ocean.

Example, *Micippa Philyra.* Length about two inches; colour yellowish.

Locality.—The Indian Ocean and the coasts of the Isle of France.



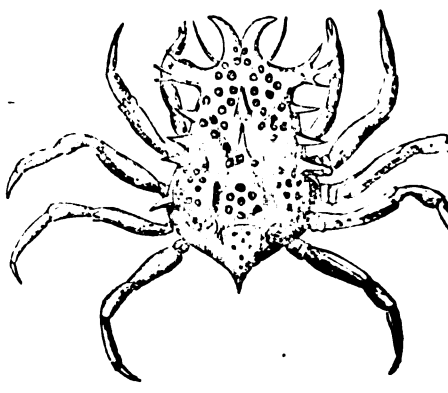
Micippa Philyra.

Criocarcinus. (Guérin.)

The principal characters of this extraordinary genus are found in the disposition of the orbits and of the eyes. The *orbitary cavities* have nearly the form of a long and truncated tube directed outwards; but they do not sheath the eyes as in *Pericera,* for the ophthalmic ring advances nearly to their extremity, and the ocular peduncle, which is long, slender, and like that of *Maia,* is inserted so as to be completely exposed, and to be capable of reflection backwards, and of applying itself throughout its length against the external border of the basilary joint of the external antennæ, a position in which it is concealed under the post-orbital spines of the carapace.

Example, *Criocarcinus superciliosus; Cancer superciliosus* (Herbst). Length eighteen lines.

Locality unknown.



Criocarcinus superciliosus.

Paramicippa. (Milne Edwards.)

Approaching nearly to *Micippa. Carapace* nearly as wide as it is long, *rostrum* bent back below, and the latero-anterior borders armed with teeth. Disposition of the external *antennæ* nearly the same as in *Micippa,* except that the second joint, which is placed on the same level as the upper part of the front, is flattened, enlarged, very thin, and triangular or heart-shaped. The disposition of the *eyes* is very different, for they cannot be reflected backwards, and there is no post-foraminal orbitary cavity; their pe-shows much beyond the edges of the orbit, and presents the same disposition as in the *Doclearia*, except that they are immoveable. Form of the external *jaw-feet* the same as in *Pisa*; but the *epistome* is extremely short. The *feet* are short, those of the second pair hardly longer than the post-frontal portion of the carapace; the succeeding feet are gradually shortened. The *abdomen* of the female is composed of seven joints.

Geographical Distribution of the Genus.—The only certain locality stated by M. Milne Edwards is the Red Sea.

Example, *Paramicippa tuberculosa*. There are some hairs on the feet, and even on the carapace. Colour brownish.

Locality unknown.

Pericera. (Latreille.)

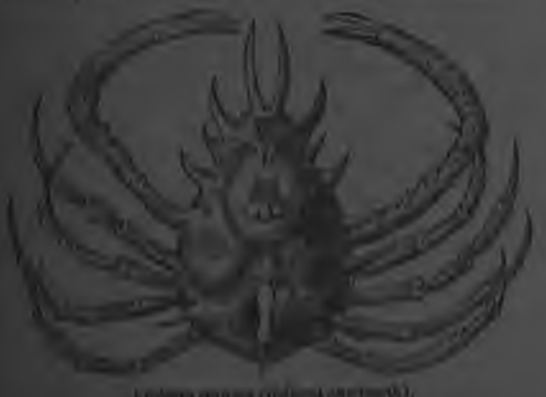
Bearing much resemblance to *Pisa*, but differing from that genus in many characters, and especially in the disposition of the orbits. *Carapace* very much elongated, and more or less triangular, a little convex, and unequal above. *Rostrum* horizontal, and formed by two great conical horns. Front very wide, and occupying nearly twice as much space as the base of the rostrum. *Orbits* circular, very small and extremely deep, directed outwards, and entirely filled by the ocular peduncles, which are enclosed therein as in a sheath, scarcely pressed beyond it, and cannot be reflected forwards or backwards; their upper border is very much produced, and presents a fissure. The basilary joint of the *external antennæ* is very large, and presents nearly the same dispositions as in *Micippa*, for it is much wider in front than it is behind, and terminates by a very extensive transversal border, which is soldered to the front on the sides of the rostrum. The position of the moveable stem of the external antennæ varies a little; sometimes it is inserted under the rostrum, sometimes a little outside the lateral border of that prolongation, but always very near the antennary fossæ, and very distant from the orbit. Disposition of the external *jaw-feet*, as well as that of the sternal plastron, the *feet*, and the *abdomen*, nearly the same as in *Pisa*.

Geographical Distribution of the Genus.—The seas of the Antilles, as far as is yet known.

M. Milne Edwards divides the genus into two sections. The first, consisting of those species in which the anterior angles of the superior orbitary border are prolonged into a stout spine, which much exceeds the basilary joint of the external antennæ; the second, of those species which have the terminal tooth of the basilary joint of the external antennæ going much beyond the anterior angle of the superior orbitary border.

We select as an example *Pericera cornuta*, M. Edwards; *Cancer cornutus*, Parra; *Cancer cornutus*, Herbst; *Maia Taurus*, Lam.; *Horned Crab*, Hughes, who describes the whole animal as 'covered with brownish plushy hairs.' Length from three to four inches.

Locality.—The seas of Barbadoes, and the Antilles.



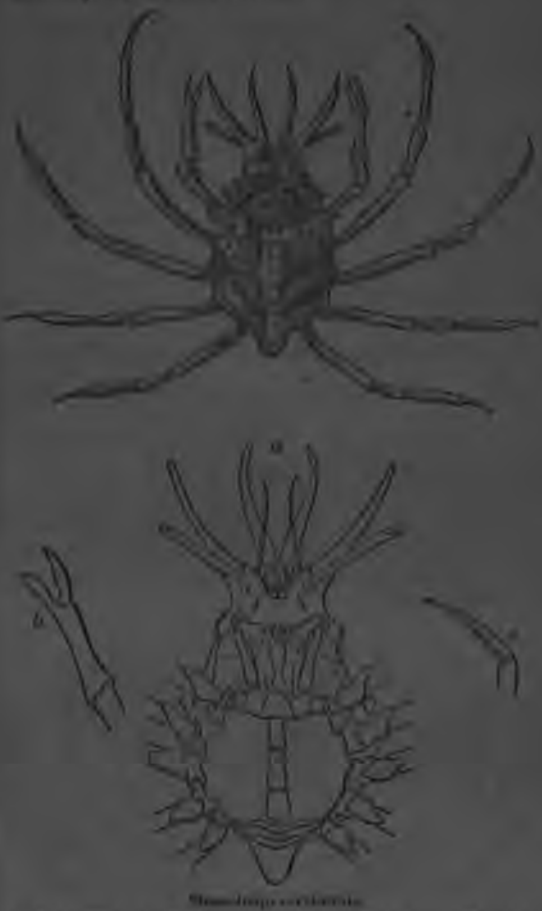
Pericera cornuta (Cancer cornutus).

Stenocinops. (Latreille.)

Approaching *Pericera*, the principal difference being in the disposition of the eyes. *Carapace* narrow, very elongated, and furnished posteriorly with a large triangular prolongation, which covers the insertion of the abdomen; *rostrum* formed of two very long and divergent horns; upper border of the orbit armed with a spine analogous to that of the *rostrum*, but directed more obliquely. *Ocular stems* delicate, immoveable and very projecting; *internal antennæ* presenting nothing remarkable; first joint of the external antennæ much longer than it is wide, the second slender and inserted under the rostrum a little in front of the level of the eyes. *Epistome* nearly square, and the third joint of the *external jaw-feet* dilated towards the external and anterior angle. *Feet* slender and cylindrical; in the female those of the first pair are hardly shorter than the others, and are much smaller than those of the second pair. *Abdomen* of the female composed of five joints only, the three rings which precede the last being soldered together. Neither Herbst, Latreille, M. Guérin, nor M. Milne Edwards appears to have examined a male.

Only one species, *Stenocinops cervicornis* (Latr.), *Cancer cervicornis* (Herbst), is known. Length from about two to three inches.

Locality.—The Isle of France.



Stenocinops cervicornis.

a, Under side in detail; b, terminal part of one of the feet of the first pair; c, termination of one of the succeeding feet.

Menæthius. (Milne Edwards.)

With much of the habit of *Pisa*, and establishing the passage between that genus and *Halimus*. *Carapace* about once and a half as long as it is wide, very much narrowed anteriorly, and of the form of a triangle rounded at its base. *Rostrum* formed by a large pointed process, which is placed on the median line of the body, and occupies about a third of the total length of the carapace. The anterior angles of the orbits surmounted by a large pointed and horizontal tooth directed forwards; the borders of these cavities without fissures, and exactly surrounding the base of the ocular peduncle, which is short and but little moveable. The disposition of the external *antennæ*, of the external *jaw-feet*, and of the thoracic *feet*, the same as in *Pisa*, except that there exist on the lower surface of the tarsi two rows of horny points. The *abdomen* of the male composed of seven distinct joints; that of the female of five only, of which the penultimate is formed by the soldering of three rings.

Example, *Menæthius Monoceros*. Length about ten lines; rostrum fringed with hairs; colour brownish.

Locality.—The Red Sea and the Indian Ocean.

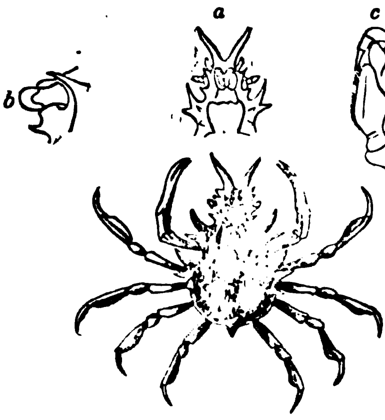
Halimus. (Latreille.)

M. Milne Edwards looks upon this genus as establishing the passage between the Eurypods, the Pisæ, the Menæthii, and the next genus.

Carapace, including the rostrum, about once and a half as long as it is wide, and convex above. *Rostrum* advanced, and formed of two divergent horns; superior orbitary border projecting, and the latero-anterior borders of the carapace nearly always straight, and armed with strong spines. Eyes not retractile, and exceeding considerably the edges of the orbit, which is prolonged backwards with a groove which represents the post-foraminary portion. First joint of the *external antennæ* very long, straight, and nearly of the same width at its extremity as at its base; the insertion of the moveable stem of these appendages not covered by the rostrum. The *epistome* very large, and nearly square. Third joint of the *jaw-feet* strongly dilated outwardly. *Pterygostomian regions* very small. Anterior *feet* slender and of moderate length in the male as well as in the female. The succeeding feet long, slender, and compressed; their penultimate joint enlarged below, and truncated like a subcheliform claw. *Abdomen* of the male composed of seven segments; that of the adult female of five.

Geographical Distribution of the Genus.—The East Indian Ocean.

Example, *Halimus Aries.* Length about an inch.

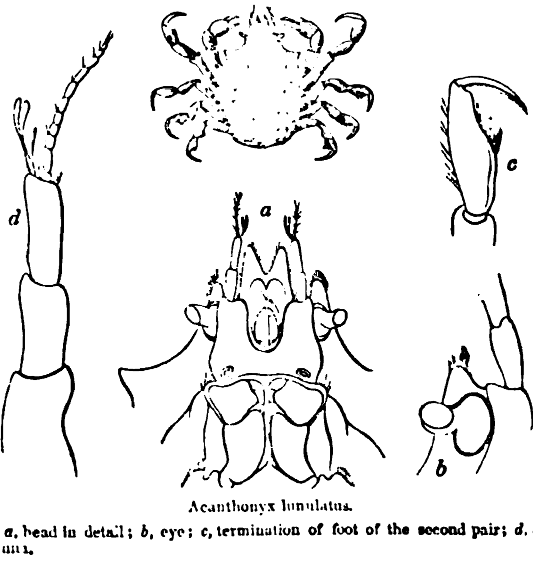


Halimus Aries.

a, head in detail; b, eye; c, pedipalp.

Acanthonyx. (Latreille.)

Carapace nearly as elongated as in *Halimus*, but less convex and much less spiny. *Rostrum* horizontal and formed of two flattened and divergent horns. *Orbits* circular and occupied entirely by the base of the ocular peduncle, which passes beyond them remarkably. Disposition of the *antennæ*, of the *epistome*, and of the *jaw-feet*, nearly the same as in *Halimus*. *Feet* short and stout; those of the four last pair very much compressed; fifth joint enlarged below, notched near the end with a hairy tooth, against which the finger is bent back in manner of a claw; those of the second pair show this structure most clearly.



Acanthonyx lunulatus.

a, head in detail; b, eye; c, termination of foot of the second pair; d, antenna.

Geographical Distribution of the Genus.—The form is widely spread. Species are recorded from the Mediterranean, from the Antilles, and from the Cape of Good Hope.

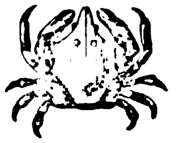
Example, *Acanthonyx lunulatus.* Length about 8 lines; body smooth, with some fasciculi of hairs on the front; colour deep green. *Localities*, the coasts of Provence and the Bay of Naples, where it is found in crevices of the rocks overhung with *algæ*.

Epialtus. (Milne Edwards.)

Establishing in some respects, according to the opinion of M. Milne Edwards, the passage between *Doclea* and *Acanthonyx*, but much more nearly approximated to the latter. *Carapace* between circular and hexagonal, scarcely longer than it is wide, regularly convex and smooth above. *Rostrum* narrow, triangular, and little or not at all divided; latero-anterior borders of the carapace very short, and forming with the lateral borders a very open angle. *Eyes* very short and not projecting much beyond the orbit, which is circular and with entire borders; but the eyes nevertheless appear susceptible of being recurved a little backwards. *Antennary region* very small; moveable stem of the external *antennæ* inserted under the rostrum, at a considerable distance in front of the orbit, and the basilary joint of these appendages nearly triangular and very narrow at its extremity. It would seem to form the whole of the lower orbitary wall. The second joint of these antennæ is a little enlarged and nearly twice as long as the third. *Epistome* small and square; *external jaw-feet* large, and their third joint nearly square, not sensibly enlarged externally, and only a little notched at its anterior and internal angle, where it joins to the succeeding articulation. The *sternal plastron* nearly circular. Anterior *feet* rather strong, and the claws slightly spoon-shaped. The succeeding feet cylindrical, and on their penultimate joint a small setiferous tubercle more or less projecting; their last joint is furnished below with two rows of small spines, and has but little flexibility: the tubercle is only well apparent in the posterior feet. The second pair are much longer than the others. Segments of the abdomen varying from six to seven in the male.

Geographical Distribution of the Genus.—The coasts of Chili, as far as it is yet known.

Example, *Epialtus tuberculatus.* Length three or four lines; colour brownish yellow. *Locality.*—Chili.



Epialtus tuberculatus.

Leucippa. (Milne Edwards.)

M. Milne Edwards sees in *Leucippa* much analogy to *Acanthonyx*, and he is of opinion that the former establishes in some points a passage between the *Maians* and the *Parthenopians.*

Carapace resembling that of *Eurynome*, save that instead of being unequal and beset with spines as in them, its surface is perfectly smooth; its length exceeds its width only a little, its anterior portion is nearly triangular, and its latero-anterior borders are projecting and trenchant. *Rostrum* horizontal, projecting, very wide, and formed of two lamellar horns. *Orbits* incomplete, so that the eye cannot be hid therein completely; the superior border of these cavities is straight, and goes to rejoin the base of the first tooth from the latero-anterior border of the carapace, so as to form a triangular notch; the external edge of the basilary joint of the external *antennæ* constitutes the internal portion of their inferior wall or partition; but backwards and below they are limited by nothing, and it may be said that there is no post-foraminary portion of the orbit. The *eyes* are small and carried on a very short peduncle; when they are folded backwards they only reach a little beyond the transversal line, and they are applied on the angle of the latero-anterior border of the carapace. The first joint of the external *antennæ* is straight throughout its length; the second and the third are completely hidden under the ros-

[illegible], and the last is nearly twice as long as that which precedes it. External antennæ not very much developed. External jaw-feet with their third joint very much dilated outwards, and deeply notched at its anterior and internal angle. Feet long, compressed, and surmounted nearly throughout their length by a trenchant crest. Abdomen of the female composed of seven segments, and covering the whole of the sternal plastron; that of the male unknown.

Geographical Distribution of the Genus.—This form, as far as is known, belongs to the Pacific Ocean.

The only species known, *Leucippa pentagona*, is about four lines in length; colour pale grey (female).

Leucippa pentagona.

a, under side of the body magnified.

(*Histoire Nat. des Crustacés, &c.*)

MAIKOV, BASIL IVANOVITCH, a Russian author who gained some distinction by his talent for comic poetry, was born at Jaroslav in 1725. Although he had received but a very moderate education, a natural aptitude for writing verses and a turn for humourous satire enabled him to distinguish himself by his 'Yelisei, or Bacchus Enraged,' a burlesque poem in five cantos, the hero of which is a *yamshik*, or carter, named Yelisei, whom Bacchus takes under his protection. It is chiefly by this production that Maikov is now remembered; but the action itself is so extravagant, and the narrative in many parts so confused, as to detract considerably from the pleasure afforded by the humour displayed in many passages. He also wrote two poems in a similar vein; one entitled 'Igrok Lombera, or the L'Hombre Player;' the other, 'The Most Shocking Fall of the Poets;' each of which is in three cantos. His other works consist of two tragedies and several tales and fables. To these last mentioned productions the epithet 'Moral,' prefixed to them by the author himself, can hardly be said to belong, for one of them at least is most scandalously indecent. There is also considerable grossness in many parts of 'Yelisei.' Maikov died at Moscow in 1778, but the first entire collection of his poems did not appear till 1809, when they were published in one volume, at St. Petersburg.

MAIL (from the French *maille*, strictly 'the mesh of a net,' but applied in a collective view to defensive armour formed of iron rings or round meshes. Boyer, in his French Dictionary, translates *maille* 'a little iron ring.' Mail or malle was also the name given to a bag or small sack, at first probably because made of net-work; since applied likewise to the portmantle or portmanteau.

MAIL, COAT OF (also denominated the Hauberk or Habergeon), armour for the body, of which there were two kinds, one called chain-mail, the other plate-mail. Chain-mail consisted of a number of iron rings interlaced, each ring having four others inserted into it, the whole exhibiting a kind of net-work already described, with round meshes. Plate-mail consisted of laminæ of metal like scales fastened down to a strong quilted linen or leathern jacket. [Armour.] Compare also Grose's *Milit. Antiq.*, vol. ii.; Meyrick's *Critical Inquiry into Antient Armour*, fol., Lond., 1824; and his *Observations on the Body Armour anciently worn in England, and Upon the Lorica Catena of the Romans*, in *Archæologia*, vol. xix., pp. 120-145, 235-262.

MAIM (in law, 'mayhem') is an injury done to the body of a man by forcibly depriving him of the use of some member serviceable in fight, as a means either of defence or offence, and permanently disabling him from offering such an effectual resistance to further attacks upon his person as he otherwise might have done; as if a foot, hand, or finger, or a joint of the foot or hand, be struck off or made crooked or weakened, or if a bone of the head be removed, or a foretooth broken or displaced, or if an eye be beaten out, or if any other bodily injury be inflicted whereby the party is rendered less capable of making a vigorous defence. But disfiguration of a jaw-tooth, of an ear, or of the nose or of other members, the loss of which does not interfere with the powers of defence or of offence, does not amount to mayhem. The distinction however is by statutory alterations in the law rendered of little importance.

Mayhem was formerly punished by inflicting the same privation upon the offender which he had caused to the party maimed. It was afterwards punishable by fine and imprisonment, as an aggravated trespass. But now, by 7 Wm. IV. and 1 Vict., c. 85, to stab, cut, or wound, if with intent to murder, is a capital felony; and if with intent to maim, disfigure, or disable, is a felony punishable by transportation for life, or for not less than 15 years, or by imprisonment not exceeding three years.

Concurrently with these proceedings in the name of the crown, for the purposes of public justice, the party injured is entitled to compensation in the shape of damages, to be recovered in an action of trespass; and where the damages found by the jury are not commensurate to the injury sustained, the court may increase them upon inspection of the mayhem.

MAIMATSHIN, or MAIMATCHIN. [Kiachta.]

MAIMBOURG, LOUIS, born in France in 1610, entered the order of Jesuits, and studied theology at Rome. On his return to France he was employed as a preacher. Having published, in 1682, a work in which he defended the principles of the Gallican Church, 'Traité Historique de l'Eglise de Rome,' the pope caused him to be expelled from the order of Jesuits. Louis XIV., on this occasion gave him a pension, and he retired to the abbey of St. Victor at Paris, where he died in 1686. The four propositions which Maimbourg, with the greater part of the French clergy, maintained, are:—1. That the pope has no authority in temporal matters. 2. That the general councils of the church are superior to the pope. 3. That the pope may err in his decisions, which are subject to the approbation of the church. 4. That the rights, usages, and canons established in the Gallican Church cannot be altered by the pope without the consent of the clergy and the state.

Maimbourg wrote several works on church history, the principal of which are: 1. 'Histoire du Pontificat de St. Grégoire;' 2. 'Histoire du Pontificat de St. Léon;' 3. 'Histoire du Calvinisme,' which has been criticised by Bayle and others; 4. 'Histoire de l'Arianisme;' 5. 'Histoire des Iconoclastes;' 6. 'Histoire du Luthéranisme,' in which he defends indulgences in their fullest extent, as remitting not only the temporal penalty, but the penalty hereafter, both to the living and the dead; 7. 'Histoire de la Ligue.'

Maimbourg is often prejudiced and inexact, but his style is attractive, and several of his works are not destitute of merit. Voltaire, no favourable judge, said of him that 'he had been too much praised at first, and too much neglected afterwards.'

MAIMO'NIDES, or more properly **MOSES BEN MAIMON**, one of the most celebrated of the Jewish Rabbis, was born at Cordova in Spain, about A.D. 1131 or 1133. He studied philosophy and medicine under the celebrated *Averroes*, an Arabian physician and philosopher; and also paid great attention to mathematics and natural science, as far as they were known at that time. In addition to a knowledge of Hebrew and Arabic, he is also said to have been acquainted with Greek, and to have studied the writings of the most celebrated Grecian philosophers.

In consequence of a violent persecution having arisen against his master Averroes, Maimonides withdrew to Egypt, where he is said to have gained his livelihood at first by working at the trade of a jeweller. His great merits afterwards introduced him to the sultan Alphadel, who appointed him physician to his own household, and treated him with distinguished honour. He died in Egypt at the age of 70.

The learning and abilities of Maimonides have been universally acknowledged both by Jews and Christians, although the independent mode of thinking which characterised most of his writings, as well as his rejection of some of the favourite absurdities of the Rabbis, rendered him an object of suspicion and dislike among many of his contemporaries. The Rabbis of Montpelier in particular attacked his opinions with the greatest vehemence, and burned his writings; but their proceedings were censured by most of the Spanish Rabbis. The controversy continued till about the year 1232, when the celebrated David

Kimchi was chosen by both parties as an arbiter of the dispute. [Kimchi.]

The most celebrated of the writings of Maimonides are: 1. *Moreh Nevochim*, or 'Teacher of the Perplexed,' originally written in Arabic, and translated into Hebrew by his disciple Samuel Aben Tybbon. This is perhaps the most valuable work of Maimonides; it contains an explanation of difficult passages in the Old Testament, as well as of types, allegories, &c. The original Arabic has not been printed; but the Hebrew translation has been published at various times; the best edition is by Salomon Maimon, Berlin, 1791. The 'Moreh Nevochim' has been also translated into Latin by Justinian, bishop of Nebio, Paris, 1520, and by the younger Buxtorf, Basel, 1629, with a preface, which contains an account of the life of Maimonides. Dr. Townshend has published an English translation of this treatise, under the title of 'The Reasons of the Laws of Moses, from the "More Nevochim" of Maimonides,' London, 1827. 2. *Perush ha-Mishna*, or 'Commentary on the Mishna,' which was also originally written in Arabic, but has been translated into Hebrew by many Rabbis, and has usually been published with editions of the 'Mishna.' Surenhusius, in his edition of the 'Mishna,' Amst., 1698-1703, has given a Latin translation of this work. Part of it was published in the original Arabic by Pococke, Oxford, 1645, under the title of *Porta Mosis*. 3. *Yad Hazakah*, or 'The Strong Hand,' which contains a complete digest of the Hebrew laws. It is written in remarkably good Hebrew. The best edition is that printed at Amsterdam, 1702, 4 vols. fol. 4. *Shelosh Asarah Ikkarim*, or 'The Thirteen Articles of Faith,' printed at Worms, 1529, and Jena, 1540.

Maimonides also wrote several other treatises on different points of the Jewish law, and many works on medical subjects. He also translated, at the command of the sultan of Egypt, the writings of the Arabian physician Avicenna, or Ibn Sina.

Maimonides founded a college at Alexandria for the instruction of his countrymen, in which he delivered lectures on philosophy and the Jewish laws.

MAIN, UPPER AND LOWER. [Bavaria.]

MAINA, a district of the Peloponnesus, which occupies the south-west part of the antient Laconica, extending along the range of the Taygetus to Cape Matapan. The inhabitants of this mountainous district were never subjugated by the Turks, but lived in a kind of savage independence, often making incursions into and plundering the neighbouring districts occupied by the Turks: some of them also scoured the sea as pirates. Their chief, who was hereditary, was styled Bey, but his authority was much circumscribed by the council of the primati, or heads of the principal families. The number of the Mainiótes has been variously stated, by some as high as 40,000. Thiersch (*De l'Etat actuel de la Grèce*) states the eparchy of Maina to contain about 3000 families; but this includes merely the southernmost part, or rocky peninsula between the Laconian Gulf and that of Coron; but the name of Mainiotes was given in general to all the mountaineers of West Laconica. They are now subjects, though not very docile ones, of the new kingdom of Greece.

MAINE, LE, one of the provinces into which, before the Revolution, France was divided, was bounded on the north by the duchy of Normandie; on the east and south-east by the districts of Chartrain, Dunois, and Vendômois, portions of Orléanais, and by Touraine; on the south by Anjou, and on the west by Bretagne. Its length may be estimated at 113 miles from east to west; its breadth from north to south at about 59: its area may be estimated at 3886 square miles. It was watered in the western part by the Mayenne; and in the central and western parts by the Sarthe and its branches. It was subdivided into Haute (or Upper) Maine in the centre, Bas (or Lower) Maine in the west, and Le Perche in the east. The capitals of these districts were respectively Le Mans, Mayenne, and Mortagne: Le Mans was considered to be the capital of the whole province. Le Maine is now for the most part divided into the departments of Sarthe and Mayenne, except Le Perche, which is for the most part included in the department of Orne. Some small portions are included in the departments of Eure and Eure et Loir.

Le Maine derives its name from the Aulerci Cenomani, one of the Celtic tribes which inhabited it. They possessed the central and eastern parts: the Diablintes (perhaps another division of the Aulerci) occupied the north-western parts; the Arvii, the south-western; the Saii or Esuvii a small portion of the north-eastern; and the Carnutes, another small portion of the extreme east. The Aulerci Cenomani were among the nations who filled the north of Italy with a population of Gauls. Le Maine was among the earlier conquests of the Franks, who established here a kingdom, which lost its separate existence when Clovis amalgamated the Frankish tribes under his sway.

Le Maine was early formed into a county. It was ravaged by the Normans, and conquered by William the Bastard, duke of Normandie (A.D. 1063), a little before the conquest of England. The troubles of the province during his government and that of his sons, induced Henry I., his youngest son, to cede the province (A.D. 1100) to Hélie de la Flèche, a rival claimant, on whose death (A.D. 1110) it came to the counts of Anjou. On the accession of Henry, count of Anjou and Maine, to the duchy of Normandie (A.D. 1151), and subsequently to the crown of England as Henry II. (A.D. 1154), Maine again became part of the English possessions in France. On the confiscation of these by Philippe II. Auguste, the county of Maine was granted by that prince (A.D. 1204) to Bérengère or Berengaria, widow of Richard I. of England, on whose death it probably reverted to the crown, and was granted by Louis IX. (Saint Louis), together with the county of Anjou (A.D. 1246), to his brother Charles, count of Provence. Under Philippe VI. de Valois, who had inherited it before he came to the throne of France, it was reunited to the crown; but Philip, he, shortly after his accession, invested his son Jéan with the two counties, and when Jéan became king, he bestowed them on his second son Louis, who subsequently became count of Provence and king of Naples, in whose house it continued for some time. In 1440, Réné, who possessed the counties of Lorraine, Provence, Anjou, and Maine, bestowed the last on his brother Charles, who transmitted it to his son: but on the death of the latter (A.D. 1481), the county of Maine was once more reunited to the crown, from which it has never since been permanently alienated.

MAINE ET LOIRE, a department in the west of France, bounded on the north by the department of Mayenne, on the north-east by that of Sarthe, on the east by that of Indre et Loire, on the south-east by that of Vienne, on the south by that of Deux Sèvres, on the south-west by that of Vendée, and on the west by that of Loire Inférieure. The form of the department is irregular; its greatest length is from east by north to west by south, from between Le Lude and Château La Vallière to the junction of the little river Divate with the Loire, 77 miles; the greatest breadth, at right angles to the length, is from the neighbourhood of Pouancé to that of Maulevrier, 60 miles. The area is estimated at 2799 square miles, which is almost equal to the conjoint areas of the English counties of Lancashire and Cheshire. The population in 1831 was 467,871, in 1836 it was 477,270, showing an increase in five years of 9399, or about 2 per cent., and giving 170 or 171 inhabitants to a square mile. In extent of surface and in population, whether regarded as to amount or density, it is considerably above the average of the French departments; but in the latter respect far below the English counties with which we have compared it. Angers, the capital, is in 47° 28′ N. lat. and in 0° 33′ W. long., 161 miles from Paris in a direct line, and 178 miles by the road through Chartres and Le Mans.

The department has no mountains, nor are there any very high hills. The high lands which separate the basins of the Vilaine and the Loire occupy a small part of the north-western border, and the southern part is overspread by the prolongations of the heights of Gâtines, which bound the basin of the Loire on the south-west. The surface of the department consists for the most part of low hills covered with vineyards, or of gently undulating plains, divided by ditches and quick hedges, and adorned with clumps of trees, whose foliage gives variety and beauty to the landscape. The eastern side of the department is occupied by the chalk which encircles the Paris basin: a belt of land in the centre, extending across the department, first south-west along the eastern bank of the Sarthe to its junction with the Mayenne, and from thence south-east by Angers, Brissac, and Doué, is occupied by the formations between the chalk and the saliferous sandstone: the western side is occupied by the primitive rocks.

The whole department is included in the basin of the Loire, which river crosses it from east to west. It enters the department just below the junction of the Vienne, and flows westward to Ingrande 43 miles; for 12 miles below Ingrande it separates this department (which extends farther west on the south side of the Loire than it does on the north side) from that of Loire Inférieure. There are numerous islands in this part of the river. The Mayenne, the principal tributary of the Loire, enters the department on the north side, and flows south in a circuitous channel to Angers, a little below which it falls into the Loire: its whole course is about 37 miles. The Sarthe enters the department on the north side, about 12 miles east of the Mayenne, and after a tolerably direct course of 23 miles south-south-west, joins the Mayenne just above Angers. The Loir enters the department also on the north side, but about 12 miles farther east than the Sarthe, and flows south-west, though with one or two considerable bends, about 27 miles into the Sarthe, into which it falls about five miles above its junction with the Mayenne. All these rivers are navigable throughout that part of their course which lies within the department. They have no feeders of any consequence except the Oudon, which enters the department on the north-west, and after receiving the Araize and the united stream of the Argos and the Verzée, falls into the Mayenne, midway between the border of the department and Angers. Its whole course in this department is about 17 miles, for 10 of which it is navigable. The Authion or Anthion enters the department on the east side, 3 or 4 miles from the north bank of the Loire, and has a westward course of 26 miles in this department parallel to that river, into which it falls at Les Ponts-de-Cé near Angers. It receives the Latan and the Couanon. It is not marked in Brué's map of France as navigable, though included in the official statements. All the above tributaries of the Loire join it on the north bank.

South of the Loire are the Thoué or Thouet, with its tributary the Dive; the Aubance; the Layon, with its tributary the Hyrome; the Evre; and the Divatte; which successively fall into the Loire. The Divatte, the most westerly of them, separates this department from that of Loire Inférieure. The Thoué, the Dive, and the Layon are given in the official statements as navigable, but only the Thoué is marked as being so in Brué's map. The Sèvre Nantaise skirts the south-west border of the department, and its tributary the Moine waters the south-west part. The statement of the inland navigation of the department is thus given in the 'Statistique de la France,' printed by the French government:—

	Miles
Loire	54
Mayenne	50
Sarthe	27
Loir	23
Oudon	11
Authion	26
Thoué	14
Dive	9
Layon	37
	251

There were (January 1, 1837) nine Routes Royales, or government roads, having an aggregate length of 248 miles, namely, 87 in repair, 144 out of repair, and 17 unfinished. The principal road is that which leads from Paris by Chartres and Le Mans to Angers, and from thence to Nantes. It enters the department between La Flèche (Sarthe) and Durtal, following the right or north-west bank of the Loir; at Durtal it crosses that river and runs south-west to Angers. From Angers it runs west-south-west along the valley of the Loire by St. George's to Ingrande, beyond which it enters the department of Loire Inférieure. Another road from Paris to Angers by Tours enters the department on the east, and follows the north bank of the Loire, through Rosiers and St. Mathurin. Roads lead from Angers along the valley of the Mayenne west of that river, by Le Lion d'Angers, to Laval, and by Les Ponts-de-Cé across the Loire, by St. Lambert, Chemillé, Trémentines, and Cholet, to Bourbon Vendée and Les Sables d'Olonne (Vendée). A road from La Flèche runs south by Baugé and Longué across the Loire to Saumur, from whence one branch continues southward by Montreuil Bellay to Parthenay and Niort (Deux Sèvres); another runs south-south-west by Doué, Vihiers, Coron, and Vezins to Cholet. There were at the same date twenty-four Routes Départementales (departmental roads), with an aggregate length of 332 miles, of which 143 were in good repair, 15 out of repair, and 174 unfinished. The number of bye-roads and paths was above eight thousand; their aggregate length more than 5500 miles. Few departments would be so well provided with means of communication by land and water, if the roads were kept in good repair.

The soil is in general fertile, and the quantity of waste land is but small. Nearly two-thirds of the department are under the plough. The quantity of corn raised is considerably above the consumption of the department. The exports amount sometimes to more than 500,000 hectolitres, or more than 170,000 quarters. Pulse of all kinds is grown, especially beans and kidney-beans, of which 20,000l. worth are sent to Nantes and Bordeaux for sea stores. Hemp and an abundance of excellent fruits are raised, especially melons, almonds, and plums. Pears and apples are cultivated, the latter for cider. The vineyards occupy 75,000 to 80,000 acres, and yield on an average nearly 500,000 hectolitres, or above 11,000,000 gallons of wine of fair quality. The best wines are the red wines of Neuillé and Champigné-le-Sec, and the white wines of Varrains, Clos-Morin, Saumur, Rablais or Rablay, Faye or Fay, and Bonnezeaux. The quantity of meadow-land is considerable, about 200,000 acres. A considerable number of horned cattle are reared, and of sheep of a breed crossed with the merinos. The Thibet goat has been introduced. The breed of horses has been improved by means of the royal stud established at Angers. The woods occupy about 150,000 acres, and consist chiefly of oak and beech trees. Game and fish are abundant.

Among the mineral treasures are granite, marble of various qualities, excellent building-stone, sandstone for pavements, roofing slates of excellent quality and great abundance [ANGERS], limestone, iron, and coal. The quantity of coal dug in 1835 was 17,355 tons. There was in 1834 only one iron-work, having one furnace for smelting pig-iron, and six forges for the manufacture of wrought iron. Charcoal was the fuel employed.

The department is divided into five arrondissements, as follows:—

		Area in Sq. Miles.	Population in 1831.	Population in 1836.	Communes.
Angers,	Central & W.	610	124,389	136,189	92
Baugé,	N.E.	559	81,998	84,605	67
Beaupréau,	S.W.	693	104,787	108,919	73
Saumur,	S.E.	576	89,400	91,118	93
Segré,	N. & N.W.	461	57,181	58,169	61
		2799	467,871	477,270	384

There are thirty-four cantons, or districts, each under a justice of the peace.

In the arrondissement of Angers are, Angers (pop. in 1831 28,933 for the town, 32,743 for the commune; in 1836, 35,901 for the commune) [ANGERS], on the Mayenne; St. Mathurin, Les Ponts-de-Cé, Savennières, St. Georges, and Ingrande, on or near the north bank of the Loire; Blaison, Rochefort, and Chalonne, on the south bank of the Loire; and St. Aubin, on the Layon. St. Mathurin is in one of the pleasantest parts of the valley of the Loire, and consists of about 400 houses, the greater part of which are on the north side of the road from Tours to Angers, the opposite side of the road forming a kind of terrace immediately above the bank of the Loire. The town of Les Ponts-de-Cé, formerly written Ponts-de-Sai or Sée, takes its name from a line of bridges and causeways extending nearly two miles in length across the arms of the Loire and the islands encircled by them. The houses on each side the causeway form the town, which comprehends two parishes, forming one commune, with a population of 2495 for the town, or 3665 for the whole commune. The bridges have their foundations of slate, and are in a very dilapidated condition; they do not however present any marks of great antiquity. Near the south end of the bridge, on an island of the Loire, are the ruins of a Roman causeway; and at some distance from the northern end of the bridge, at the confluence of the Loire and the Mayenne, is a large Roman camp, capable of containing 100,000 men, and forming an equilateral triangle, defended on two sides by the rivers and on the third by an entrenchment. Many medals and coins with other antiquities have been dug up here. Ingrande has a large glass-house for the manufacture of bottles; it employs about 300 workmen. Chalonne or Chalonnes (pop. 2239 town, 4969 commune) is in a delightful situation. There are the ruins of an old bridge and castle. The inhabitants are chiefly boatmen and weavers: the latter make serges for home consumption, or handkerchiefs for the merchants of Chollet. Black marble is quarried near the town.

In the arrondissement of Baugé are, Baugé (pop. in 1831, 3433 town, 3553 whole commune; in 1836, 3400 commune) and Beaufort (pop. 3288 town, 5914 commune), on or near the Couanon [BAUGE'; BEAUFORT]; Longué (pop. 1577 town, 4491 commune), and Vernantes, on or near the Latan; Durtal (pop. 3465) on the Loir; Moranne, on the Sarthe; and Jarzé. Durtal or Duretal has the remains of an old castle built by Foulques Nera, count of Anjou, consisting of two towers, having a parapet with machicolations. The other parts of the castle are of later date. There is a good stone bridge of five arches over the Loir.

In the arrondissement of Beaupréau are, Beaupréau (pop. in 1831, 3207; in 1836, 3288) [BEAUPREAU]; Le May (pop. 3315), and Montrevault, on the Evre; Jallais (pop. 3163) on a small feeder of the Evre; St. Florent, on the south bank of the Loire; Maulevrier, La Tessouale, Chollet (pop. 4657 town, 7345 whole commune) [CHOLLET], and Montfaucon, on or near the Moine; Greslé, not far from Beaupréau: Chemillé (pop. 3694) on the Hyrome; La Jumellière, Trementine, Tour Landry, and Vezins. Handkerchiefs, linens, and woollens are manufactured at Jallais, St. Florent, Chemillé, Trementine, and Vezins. Le May was destroyed in the Vendéan war, but has been restored. La Tessouale has a considerable establishment for bleaching linen.

In the arrondissement of Saumur are, Saumur (pop. in 1831, 9977 town, 10,652 whole commune; in 1836, 11,925 commune) [SAUMUR]; Montsoreau, and Fontevrault on or near the south bank of the Loire; Roziers, on the north bank; Brissac on the Loubancy; Passavant, Neuil, Les Verches, Doué (pop. 2479), Martigné, Chavaignes, Thouarcé, Rablay or Rabelais, and St. Lambert, all on or near the Layon; Montreuil-Belloy (pop. 1812 town, 1907 whole commune); Coudray, and Puy Notre-Dame, on or near the Thoué; Vihiers, Coron, La Salle, and Gonnord. In the old abbey of Fontevrault, Henry II. and Richard I., kings of England, were buried. Doué has some remains of an old palace of King Dagobert; the ruins of what some have regarded as a Roman amphitheatre hollowed out of a calcareous rock, others as the ruins of an old palace of the kings of Aquitaine; a handsome fountain, and in the neighbourhood some extensive caverns. On the south bank of the Loire below Saumur are the entrenchments, in good preservation, of a camp supposed to be Roman, forming a vast but irregular polygon approaching to an oval. Fragments of Roman pottery and medals of different emperors, from Augustus to the Antonines, have been dug up in this neighbourhood, and round the camp are many vestiges of tombs. At Gennes on the south bank of the Loire, a little lower down, are some other Roman antiquities, and especially the ruins of an aqueduct.

In the arrondissement of Segré are, Segré and Le Lion d'Angers, on the Oudon; Pouancé, near the source of the Verzée; Candé, on the Erdre, a stream which belongs chiefly to the department of Loire Inférieure; and Châteauneuf, on the Sarthe. Segré is a small place, consisting of a few crooked streets or rather lanes, in a situation out of the way of any great thoroughfare, and from the badness of the roads scarcely accessible. The population of the town is probably little more than 800; that of the whole commune was, in 1836, only 2130. Le Lion d'Angers is agreeably situated on the right bank of the Oudon, which is here navigable, a little above its junction with the Sarthe. It is a well built town, favourably situated on the road from Laval to Angers, with a population probably of 2500. Pouancé has some iron-works, with a population probably of about 2000.

The population, where not otherwise specified, is that of the whole commune, and from the returns of 1831.

The manufactures of the department comprehend sail-cloth, handkerchiefs of various colours and of different qualities, coarse linens, and other linens called 'cholettes,' coarse woollen cloths, and woollen stuffs, cotton-yarn, paper, leather, and wax candles. There are also mills or presses for walnut, linseed, and other oils. Trade is carried on in corn, trefoil-seed, dried pulse, wine, brandy, vinegar, paper, cattle, slate, marble, and coal.

The department constitutes the diocese of Angers, the bishop of which is a suffragan of the archbishop of Tours. It is in the jurisdiction of the Cour Royale and the circuit of the Académie Universitaire of Angers, and in the fourth military division, the head-quarters of which are at Tours. It returns seven members to the Chamber of Deputies.

In respect of education this department is very backward: of every hundred young men enrolled in the military census of 1828-29 only twenty-three could read and write; the average of France being thirty-nine.

This department originally formed part of the territory of the Andecavi or Andes, north of the Loire; and of the Pictones, south of that river. In the subdivision of Roman Gaul the former was included in Lugdunensis Tertia, the latter in Aquitania Secunda. The chief town of the Andes was called at first Juliomagus; afterwards, from the name of the people, Andes or Andecavi, the modern Angers. Combaristum, now Combrée, a village between Segré and Pouancé, and Robrica, probably the bridges of Longué on the Latan, were towns of the Andecavi. In the middle ages, and up to the time of the Revolution, the department constituted the greater part of the province of Anjou.

MAINE is the most northern of the United States of North America, being bounded on the south-west and west by New Hampshire, on the south by the Atlantic Sea, on the east by the British colony of New Brunswick, and on the north and north-west by Canada. The United States claim as an appurtenance of Maine all the extensive country traversed by the St. John river and its tributaries west of the boundary-line of New Brunswick (67° 50′ W. long.), which is considered by the British as belonging to Canada. This disputed tract lies between 46° and 48° N. lat., and between 67° 50′ and 70° [illegible]′ W. long. Exclusive of this tract, the state of Maine extends from 43° 5′ to 46° 30′ N. lat., and between 67° and 71° W. long. Its greatest length, from south-south-west to north-north-east, is about 270 miles; and its greatest width, from east to west, about 180 miles. Its surface may be estimated at about 22,000 square miles, or between 3000 and 40[illegible] square miles less than the area of Ireland.

Coast, Surface, and Soil.—The coast-line extends in a straight line 236 miles. The southern portion, as far north as Casco Bay, is rather high, but comparatively free from rocks and islands. Casco Bay extends from south-west to north-east 20 miles, with a mean width of five miles, and is landlocked by a chain of islands. So far the coast trends from south-south-west to north-north-east. Between Casco Bay and Penobscot Bay the coast of the mainland runs nearly west and east; but numerous [illegible] peninsulas stretch out from it southward into the sea. [illegible] are divided from each other by narrow and deep indentations, which form excellent harbours. These bays contain numerous small islands. Penobscot Bay extends from St. George's Point (44° N. lat.) and the Fox Islands, thirty miles northward, to the mouth of the Penobscot river, nearly in a northern direction. It contains numerous wooded islands, some of which are considerable, as Long Island, which is fifteen miles in length and from two to three in breadth, Fox, Deer, and Haut islands. The remainder of the coast-line, from Penobscot Bay to Passamaquoddy Bay, resembles the coast west of Penobscot Bay, consisting of an alternation of promontories and indentations; but the former are commonly wider, and the inlets do not run so deep into the mainland. The most extensive bays are Frenchman's Bay and Machias Bay. Frenchman's Bay is formed on the west side by the extensive island called Mount Desert Island. The approach to this coast, which runs from the south of west to the north of east, is also rendered difficult by numerous rocks and small islands. Though the frost along this shore is very intense in winter, and the numerous islands favour the formation of ice, the harbours are commonly open all the year round, the strength of the tide, which rises from between 24 to [illegible] feet, preventing their being closed up. The country rises gradually from the shore, but rather rapidly, which is proved by the tide entering the rivers only a few miles, especially towards the south. The surface of the state is mostly hilly, but it is only in the north-western and northern districts that the hills rise to the height of mountains. The mountain-region may be considered as divided from the [illegible] country by a line beginning on the south on the banks of the Androscoggin river, at the mouth of Swift river (70° [illegible] W. long), and running north-north-east towards the southern extremity of Moose-Head Lake, from which point it extends east to the place where the west or main branch of the Penobscot river unites with the Matawamkeag river

East of that branch of the Penobscot the mountains remain northwards to about 46° N. lat. The region to the west and north of this line is full of high hills and mountains, of which the highest, Mount Katahdin, rises to more than 5300 feet. These hills, though mostly isolated, occupy a considerable surface, perhaps one-fourth of the region, and about as much is occupied by the lakes. The lowest part of this region is probably from 600 to 700 feet above the surface of the sea; and few, if any, settlements have been formed in it, except at the southern extremity, in the valley of the Androscoggin, where the hills are of moderate elevation. This region occupies more than one-fifth of the area of the state.

The remainder of the state is occupied by the hilly region, which is well drained by numerous rivers with a rapid course. Swamps are of rare occurrence in this part and of moderate extent, except along the banks of the Mattawamkeag, where they occupy a space fifty miles in length. Along the sea-coast, and from ten to twenty miles inland, the soil is of moderate fertility, and frequently intersected with sandy and sterile tracts; but beyond this region the soil improves, and produces plentiful crops of grain, flax, and hemp.

Rivers and Lakes.—The rivers in the southern district have a short course. The principal are the Piscataqua [New Hampshire], the Saco, and the Presumscot, or Casco. The two latter rise on the southern and western declivity of the White Mountains in New Hampshire, the Saco running about 80 and the Presumscot about 60 miles. The latter traverses a large lake called Sebago Pond, and falls into Casco Bay, a short distance north of Portland.

East of Casco Bay is a deep indentation which receives two considerable rivers, the Androscoggin [Androscoggin] and the Kennebeck. The Kennebeck rises in several branches on the eastern declivity of the mountain-range which separates Maine from Canada: these branches, some of which have a course of 40 miles, unite in Moose-Head Lake, a sheet of water about 30 miles long from north to south, with a breadth varying from five to six miles. From the south-western side of this lake the Kennebeck issues in a large stream, and the general direction of the remainder of its course is to the south, but with considerable deviations to the west and east, until it reaches the mouth of the Androscoggin, after a course of about 150 miles. Though its course is obstructed by falls and shoals, like that of the Androscoggin, it is of great importance in the transportation of lumber. The tide ascends to Augusta, 70 miles from the open sea. Kennebeck Bay, in which the Androscoggin and the Kennebeck unite, stretches more than 20 miles farther south, being formed by the long peninsula of Phippsburg on the west, and by numerous islands on the east.

The upper branches of Penobscot river are numerous. All the waters which descend from the southern declivity of the high land which forms the southern border of the St. John's river, between 68° and 70° W. long., flow down to the Penobscot. The principal branch is the western, which is formed by several mountain-streams uniting in Chesuncook Lake, from the southern extremity of which it issues with an eastern course. Skirting the southern declivity of Mount Katahdin, it enters Pamadumpcook Lake, and after leaving the lake unites with the north branch and the Mattawamkeag, two large rivers which come from the north. At the point of its junction with these two rivers it turns by degrees from an east-south-eastern to a south-western course, in which direction it continues to its junction with the Piscataquis river, a large stream which falls into it from the west. The remainder of its course is a little to the west of south, and it falls into Penobscot Bay after a course of 210 miles, the bay included. The tides come up to Bangor, 30 miles from the bay, and 60 miles from the open sea. Penobscot river is more navigable than the other rivers of Maine, as no obstruction occurs for 30 miles above Bangor, except its rapid current, and it is much used for the transport of lumber.

From Penobscot Bay to that of Passamaquoddy, a distance of 100 miles along the margin of the ocean, no large river empties itself into the sea. The last remarkable river is the St. Croix, or Scodic, which forms the boundary-line in this part between the United States of North America and the British colony of New Brunswick. Its farthest sources are a number of lakes, extending from north to east, and extending in length about 40 miles; they are known by the name of Grand or Chepuntucook Lake. The river issuing from the lake, called also Cheputnaticook, runs southward until it unites with the outlet of another series of lakes called the Scodic lakes. Hence its course is to the south-east, but with some considerable bends. It enters Passamaquoddy Bay after a course of about 100 miles. Passamaquoddy Bay is of a very irregular form, extending upwards of 20 miles from the mouth of the Scodic river to Quoddy Point; on the side of Maine it forms a bay of considerable extent, called Kopscook Bay.

Climate.—The winter is very severe. From the 1st of November to the 1st of April the ground is covered with snow, and the rivers and lakes with ice. The summer on the sea-shore is very hot. The thermometer frequently rises to 90°, and even 96°, and the weather is subject to sudden and great changes. Drought is frequent. The mean temperature is about 42°, or about eight degrees less than that of London. In the year the thermometer ranges 115°; between 95° above and 19° below zero. In the interior of the hilly region the weather, though not so warm, is much more regular. Little is known of the climate of the mountain region. The climate all over the state is healthy; but perhaps the swampy district on the north-east must be excepted.

Productions.—A very dense forest covered Maine in its natural state, and still spreads over the greatest part of it, the settlements being yet restricted to a comparatively narrow zone along the sea-coast. These forests, consisting principally of white pine, spruce, maple, beech, birch, white and grey oak, constitute the principal wealth of the state; timber being its staple. The cultivated fields do not occupy one-twentieth part of the surface. Indian corn, which constitutes the principal food of the inhabitants, thrives well as far north as the valley of the lower Penobscot river, but farther north it does not ripen. Other articles cultivated in this state are wheat, rye, barley, oats, peas, hemp, and flax. The fruit-trees of northern Europe thrive very well, especially pears and apples, as well as most of our vegetables.

Cattle and hogs are numerous, and afford articles of exportation. Deer were formerly abundant; wolves, bears, beavers, foxes, and squirrels are still common. The sea abounds in fish, especially cod; and the rivers and lakes are full of fish, especially salmon: large trout are common in the lakes in the interior.

Maine, so far as it has yet been explored, is not rich in minerals, but iron-ore occurs in several places.

Inhabitants.—The population amounted, in 1820, to 297,839, but had increased in 1830 to 399,460; which gives about 12 individuals to a square mile. More than one half of that number is occupied in the forests, cutting the timber, and preparing other articles for exportation, as potash, pitch, &c. Many families along the sea-coast obtain their subsistence by fishing. The inhabitants manufacture coarse cloth and farming utensils; and on several of the rivers there are numerous saw-mills to prepare the timber for the market, which is floated down the rivers.

In the northern part there are still some few natives, who live mostly on the produce of the chase and of their fishery in the lakes. Their numbers seem not to exceed one thousand. The most numerous are the Penobscots, who occupy the upper and part of the central valley of the Penobscot river, in which fish abounds.

Political Geography.—Maine is divided into ten counties and 300 'towns,' a term which is equivalent to townships. The capital is Portland, situated on a promontory in Casco Bay, south of the mouth of Presumscot river. It has a large and safe harbour, which is seldom frozen over. Many vessels are built here, and it carries on a considerable foreign trade. In 1800 its population hardly exceeded 4000 souls, and in 1830 it exceeded 10,000. Along the coast are several towns with good harbours. South of Portland is Arundel with 2500, Wells with 1500, and York with 3000 inhabitants. Falmouth with 4000, Brunswick on the Androscoggin, with 3700, Kennebunk with 2500, Waldoborough with 2200, and Thomaston on the Penobscot Bay, with 3000 inhabitants, are thriving places on the coast north of Portland. At the last-mentioned places many vessels are built. On Passamaquoddy Bay is Lubeck, a town founded in 1815, and having already a population exceeding 1500. In the interior are also a few towns in the southern and most populous districts; as Berwick on the Piscataqua, with 3000, Paris with 2000, and Augusta on the Kennebeck, with 2000 inhabitants.

Bowdoin College, at Brunswick, on the banks of the Androscoggin, 26 miles from Portland, was incorporated in 1796. It is well endowed and has a good library. A medical school, in connection with the college, was established in 1820. There is also a college, founded by the Baptists in 1820, at Waterville on the west branch of the Kennebeck: and there are theological institutions at Bangor and at Readfield. The Gardiner Lyceum, at Gardiner, was established 'for the purpose of giving to farmers and mechanics such a scientific education as may enable them to become skilful in their professions.' Every town is by law required to raise annually, for the support of common schools, a sum equal at least to 40 cents for each person in the town, and to distribute this sum among the several schools or districts, in proportion to the number of scholars in each. A sum raised by a tax on banks is also appropriated to the support of the schools.

Commerce.—The exports consist chiefly of the produce of the forests, as timber, lumber, boards, and potash, and of dried fish, beef, pork, and grain. From the 1st of October, 1832, to 30th of September, 1833, their value amounted to 989,187 dollars; foreign produce exported from the harbours, to the amount of 30,644 dollars, is to be added to this amount, making a total of 1,019,831. The imports amounted in the same year to 1,380,308 dollars, and consisted mostly of manufactured articles from Europe, and salt, iron, and colonial produce from the West Indies, especially Cuba. This state possesses a larger amount of shipping than any other state in the Union except Massachusetts and New York.

History.—It appears that Maine was discovered by one of the Cabots in 1497. It was afterwards visited by the French, who called the southern part, west of the Kennebeck river, Maine, and the eastern part Acadie. In the beginning of the 17th century the English attempted to make some settlements in the southern district, and succeeded about 1635. The first charter was proprietary, and granted in 1639 to Sir Ferdinand Gorges; but in 1652 Maine was united to Massachusetts, under the title of the county of Yorkshire. In 1676 Massachusetts bought the country from the family of the Gorges, and from that time it remained annexed to that state, but thrived slowly, on account of the eternal disputes between the English and French, until in 1712 England obtained its full possession by the peace of Utrecht. Massachusetts opposed the attempts of the inhabitants to separate Maine and Massachusetts; but in 1819 it gave permission to the freemen of Maine to decide this important question, and the majority of votes being in favour of a separation, a constitution was formed and adopted, and in 1820 Maine became an independent member of the Union.

The legislative body consists of a Senate and House of Representatives, chosen annually by all the male citizens of 21 years of age and upwards. The executive is in the hands of a governor, who is chosen annually. Maine sends two members to the Senate, and seven to the House of Representatives at Washington.

MAINIOTES. [MAINA.]

MAINTENO'N, FRANCOISE D'AUBIGNE′, Marquise de, was born at Niort in 1635. Her father, Constans d'Aubigné, son of the friend of Henri IV. [AUBIGNE′, THEODORE AGRIPPA D'], was a man of profligate character. He was in prison at Niort at the time of the birth of his daughter; he afterwards went, with his wife and child, to the West Indies, where he died in 1645. His wife and daughter returned to France in a state of destitution, and Mademoiselle d'Aubigné was brought up by an aunt, and educated in the Calvinist communion, which was that of her paternal relatives. After her mother's death, her godmother, Madame de Neuillant, took her into her house, and obliged her to become a Catholic. Her situation however at Madame de Neuillant's became so unpleasant and humiliating, that she was glad to leave it by marrying Scarron, the comic poet, a man witty but old, infirm, and deformed, who felt for her the interest of compassion. Scarron's house was frequented by fashionable company, among whom Madame Scarron, by her pleasing conversation and address, made several friends. When Scarron died, in 1660, his widow was left poor; but some of her friends recommended her to Madame de Montespan, the mistress of Louis XIV., as governess to her children by the king. She thus became known to Louis, who gradually conceived great esteem for her, especially for the care which she bestowed on the Duke of Maine, one of his sons. The king made her a present of 100,000 livres, with which she purchased the estate of Maintenon. Madame de Montespan's temper was not one of the mildest, and the governess had much to endure from the imperious favourite. Louis himself was often obliged to interfere to restore peace. By degrees the king, who had grown tired of Madame de Montespan, became more strongly attached to Madame Scarron, whose conversation interested and instructed him. She had learnt, in the school of adversity, great forbearance and much tact. The king at length conferred on her the title of Marchioness of Maintenon. The queen consort of Louis was now dead. Louis was no longer young, and he felt the want of an intellectual companion and friend, to whom he could confide his thoughts. Having consulted his confessor, Father La Chaise, the latter advised a private marriage; and in 1685 Louis, who was then forty-seven years of age, was secretly married to Madame de Maintenon, who was fifty years old, by the archbishop of Paris, in presence of the Père La Chaise and two more witnesses. The marriage was always kept secret, and Madame de Maintenon herself never avowed it. Louis however lived openly with her, visited her several times a day, received his ministers in her apartments, and sometimes in their presence asked her advice upon state affairs. Without appearing to seek any political power, but rather professing to shun it, she undoubtedly exercised great influence over the king in his latter years; the choice of ministers and generals was ascribed to her by common report, and she was accused of many faults committed by the cabinet. But it would be very difficult to discriminate between those acts in which she really had a share, and those in which her influence was only supposed. Madame de Maintenon has been unjustly dealt with by many writers, and by St. Simon among the rest. She was ambitious, but not interested, arrogant, or vain; she was fond of religious discussions, and she exerted considerable power over the conscience of Louis, but she complained that 'she could never make him understand that humility was a Christian virtue.' Madame de Maintenon is still favourably remembered as the founder of the institution or school of Saint Cyr, for the education of poor girls of good families. In the latter years of Louis's life she was made unhappy by his fretful and querulous temper, and the fits of passion to which he was subject. In one of her letters she complains that 'she was obliged to please and amuse a man who would not be pleased or amused.' After the death of the king she retired to Saint Cyr, where she died in 1719.

(*Lettres de Madame de Maintenon*, 6 vols. 12mo., Paris, 1812; *Lettres inédites de Madame de Maintenon*, Paris, 1826; Lemontey, *Essai sur l'Etablissement Monarchique de Louis XIV., Pièces Justificatives, No. V., Observations sur le Mariage de Louis XIV. et de Madame de Maintenon*.)

MAINTENANCE is defined to be when a man maintains a suit or quarrel to the disturbance or hindrance of right; and if he who maintains another is to have by agreement part of the land or debt, &c. in suit, it is called Champerty. Maintenance was an offence at common law, and has also been the subject of several statutes. By the 32 Hen. VIII., c. 9, no person shall bargain, buy or sell, or by any means obtain any pretensed rights or titles to any lands, unless he who bargains or sells, or his ancestors, or they by whom he claims the same, have been in possession thereof, or of the reversion or remainder thereof, or taken the rents and profits thereof, by the space of a year next before the bargain or sale, on pain of the seller forfeiting the whole value of the lands so bargained or sold, and the buyer, knowing the same, also forfeiting the value of such lands. The professed object of the statute was to prevent the inquietness, oppression, and vexation which the preamble mentions as the consequence of the buying of titles and pretended rights of persons not being in possession of the lands sold.

A man may assign his interest in a debt after he has instituted a suit for its recovery, and such assignment of itself is not maintenance. But if the assignment be made on condition that the assignee prosecute the suit, or if the assignee give the assignor any indemnity against the costs of the suit, already incurred or to be incurred, this makes it maintenance.

(Comyn's *Digest*, 'Maintenance.')

MAINZ, or **MENTZ**, in French *Mayence*, the Roman Moguntiacum, or Moguntiacum, is the capital of the province of Rheinhessen in the grand-duchy of Hesse-Darmstadt. It is situated in one of the most beautiful and fertile parts of Germany, on the left bank of the Rhine, a little below the junction of the Maine with that river, on the slope of a hill, and it also occupies a long slip of land on the banks of the river: 49° 59' N. lat. and 8° 17' E. long. Being connected, by a bridge over the Rhine, with the strongly fortified village of Kastel, or Kassel, Mainz is one of the strongest fortresses in Europe, and a chief bulwark of Germany against France. The extent of the works, which were much enlarged by the French while the city was in their possession, including the work called the Weissenauer Schanze, but exclusive of Kastel and of the small redoubt, is two leagues and a half. Among the principal works are the citadel, with the Eichelstein, and that called the Hauptstein, an extremely strong work projecting beyond all the rest, on an eminence called the Linsenberg. Kastel, which is united with Mainz as an outwork, has very extensive fortifications, which consist of four strong forts besides the strongly fortified island of Petersau, including which latter the works are of greater extent than even those of Mainz itself. The total works consist of 13 principal and 12 smaller bastions. On the land side there are four great gates with double drawbridges, and toward the river several gates. The Rhine runs from south to north, and the Maine from east to west. About a mile above the junction of the two rivers is the village of Kostheim on the Maine, and a little farther up a bridge of boats, defended by a strong tête-de-pont. On the last settlement of the affairs of Germany by the Congress of Vienna Mainz was assigned to the grand-duke of Hesse-Darmstadt, but it was decided that, as a fortress, it should belong to the German Confederation, with a garrison of Austrian, Prussian, and Hessian troops. This garrison in time of peace consists of 8000 men. The military governor, who retains his post five years, is alternately an Austrian and a Prussian general. It has been objected to this great fortress, that it is too extensive, as it requires for its defence a garrison of 30,000 men.

Mainz is on the whole an old-fashioned and ill-built town. The streets, with three or four exceptions, are narrow, crooked, and gloomy, though there are many handsome private buildings and some fine public edifices. Of the 27 squares and market-places the principal is the Parade, which is surrounded with avenues of trees. Of the 11 churches, of which only one is for the Protestants, the most remarkable are the cathedral, the church of St. Ignatius, which is considered a model of beautiful ecclesiastical architecture, St. Peter's church, and St. Stephen's. The cathedral, founded in the twelfth century, has frequently suffered by fire. It is 350 feet long, 140 wide, and has 14 altars and 22 chapels. It was much injured in the siege by the French in 1793, and under the government of Napoleon it was intended to pull it down, but it has since been gradually repaired. Nothing however remains of the great treasures which it formerly possessed, or of its library, and even many of the fine monuments have been destroyed. Of the public edifices, we may mention the magnificent grand-ducal palace (formerly the house of the Teutonic order), the arsenal, the palaces of the commandant and of the vice-governor, the episcopal palace, the new theatre, &c. A gymnasium has taken the place of the former university, and there are several schools. The city library consists of above 90,000 volumes, and in the same building there are cabinets of medals, and of natural history, a collection of philosophical and mathematical instruments, a gallery of pictures, and a collection of Roman antiquities, comprising 27 altars and votive tablets, and above 60 lapidary stones, all found in its vicinity. The Eichelstein in the citadel is supposed to be a monument in honour of Drusus Germanicus, brother of the emperor Tiberius. Near the village of Zahlbach are the remains of an aqueduct said to have been built by the same Drusus. There are pleasant walks on the Rhine; the environs are very beautiful and the prospects over the surrounding country magnificent. The city has few manufactures; but the trade in wine is considerable.

The history of Mainz is remarkable and interesting. Its origin is supposed to have been under the Mediomatrici, who inhabited the left bank of the Rhine, and whose dominion ended in the year 70 B.C. In 13 B.C. Drusus founded the fortress of Moguntiacum, on the site on which Kastel now stands. The town which sprung up near it did not extend, under the Romans, to the Rhine. It was destroyed by the Vandals in 406, and lay in ruins for some centuries, till it was rebuilt by the kings of the Franks. A new and brilliant epoch in its history commenced with Bonifacius (Bonifacius), the apostle of the Germans, who was the first bishop. Some however affirm that Mainz has had 114 bishops and archbishops, from Crescens, who they say was a disciple of St. Paul's, and suffered martyrdom, A.D. 102, to Frederick Charles von Erthal. In 1798 Mainz became the capital of the French department of Mont Tonnerre; in 1816 it was ceded to the grand-duke of Hesse. Among the remarkable men born at Mainz are the Minnesinger Frauenlob, and Guttenberg the inventor or improver of the art of printing, in honour of whom one of the squares in the city is named, and contains a statue erected at the expense of the Casino-club. The population of Mainz is 32,000, of whom about 2600 are Protestants, 1750 Jews, and the remainder Roman Catholics.

MAIRE, JAMES LE, was the son of a merchant established at Egmont, near Alkmaar, and born about 1585. As the Dutch East India Company, which had been formed about that time, had obtained a declaration from the states-general, by which every Dutch vessel not belonging to the company was prohibited from doubling the Cape of Good Hope, some private merchants in the towns of Alkmaar and Hoorn formed a joint-stock company for the purpose of trying to effect a passage to the East Indies without doubling the Cape. Among these was Isaac Le Maire, the father of James. Two vessels were equipped for sea; the command of them was given to Cornelius Schouten, an experienced navigator, and James Le Maire was sent with him as the commissioner of the company. They set sail in June, 1615, and having passed the entrance of the Strait of Magalhaens in the following January, they continued their course southward, in the hope of finding a less difficult route to the Pacific than that through the Strait of Magalhaens. They discovered the strait between Staaten Land and Terra del Fuego on the 24th of January, and gave it the name of Le Maire. In a few days they doubled Cape Horn, being the first navigators who accomplished this undertaking. In traversing the Pacific from the east to the west, they sailed through a part of it, where only a few scattered islands occur. At last they arrived on the northern shores of New Guinea or Papua, where an island near a cape called Good Hope was named after Schouten. After visiting Gilolo, one of the Moluccas, they proceeded to Batavia, then called Jacatra. From Batavia they sailed for Europe, in a vessel belonging to the East India Company, during which voyage James Le Maire died, the 31st of December, 1616.

MAIRE, LE, STRAITS OF, lie in the Southern Atlantic Ocean, on the eastern shore of Tierra del Fuego, between 54° and 55° 30' S. lat., and are traversed nearly in the middle by the meridian of 65° W. long. They are formed on the east by the western extremity of the island of Staaten Land, and on the west by the coast of King Charles Southland, along which they extend between Cape S. Diego and Cape Good Success. These straits, which are situated in the route of vessels which intend to double Cape Horn, are about 20 miles in length and width. They are free from rocks and shoals, but still some difficulties are encountered in traversing them from the north, on account of the prevalence of western and south-western winds, and a strong current, which always sets through them from the south. They were first traversed by the Dutchmen Le Maire and Schouten in 1616, from the former of whom they received their name.

MAISTRE, A. and L. [PORT ROYAL.]

MAITLAND, SIR RICHARD, of Lethington, son of William Maitland of Lethington and Thirlstane, by his wife Martha, daughter of George, second lord Seaton, was born in the year 1496. Having completed his grammar education, he proceeded to France, at that time the common resort of his youthful countrymen, particularly for the study of the law. On his return to Scotland he was successively employed by King James V., the regent Arran, and Mary of Lorraine. Of the early part of his life however few particulars are known. In the end of the year 1550 his book of "Reports of the Decisions of the Court of Session commences; and about the same time he appears in the sederunts of the court as an extraordinary lord of session. Not many years afterwards his eldest son William, having returned from the Continent, whither he had been sent, like his father, in early life, was appointed by the queen dowager secretary of state; but afraid, as it seems, of his safety at that troublesome period, he left her and joined the Protestants in October, 1559, and in August, 1560, acted as speaker of the Convention, in which the Roman Catholic supremacy in Scotland was destroyed. In the meantime his father Sir Richard had become blind. At what time this calamity overtook him is uncertain: it was probably about the year 1559, in the end of which he concludes his 'History and Chronicle of the House and Surname of Seaton.' He continued however to report the decisions of the court of session; and what is remarkable, from about the period of his becoming blind he began to write and collect Scottish poetry. In 1562 he was made lord privy-seal; but this office he in a few years afterwards resigned in favour of his second son John, who was also the next year appointed an ordinary lord of session. His eldest son William had been some time before in the like situation, being in 1561 appointed an extraordinary lord of session, and in 1566 advanced to the place of an ordinary lord of the same court. Old Sir Richard's blindness and peaceful disposition concurred to save him from mixing in the political broils of that period; but nevertheless, in 1570, when his sons were denounced as rebels by the king's party, his lands were ravaged by the English. He lived however to know that his second son was reinstated on the bench as a lord of session, and he died only a month or so before he was advanced to the high office of chancellor of Scotland. He died on the 20th March, 1586, with the character of 'a maist unspotted and blameless judge, ane valiant, grave, and worthy knight;' but it is in his character of a writer and collector of Scottish poetry that he is now chiefly remembered.

His collections consist of two volumes: a folio, comprehending 176 articles; and a quarto, of 96 pieces, in the handwriting of Mary Maitland, his daughter. They are now preserved in the Pepysian Library, Magdalen College, Cambridge. His poetical writings were for the first time printed in an entire and distinct form in 1830, in one quarto volume, by the Maitland club, a society of literary antiquaries, so designated from this distinguished collector of Scottish poetry.

MAITTAIRE, MICHAEL, was born in France, 1688, of Protestant parents, who settled in England at the revocation of the edict of Nantes. Maittaire was educated at Westminster school under Dr. Busby, and obtained at Oxford, whither he afterwards went, a warm friend and patron in Dr. South. He took his degree of M.A. in 1696, and from 1695 to 1699 discharged the duties of second master in Westminster school. In 1699 he resigned that appointment and devoted the remainder of his life to literary pursuits. He died August 4th, 1747, at the age of 79.

Maittaire was a learned and laborious scholar. He edited many of the classical authors, with useful indexes, and also wrote several works, of which the most important are—'De Græcæ Linguæ Dialectis,' London, 1706, 1742; the best edition is by Sturz, Leip., 1807; 'Stephanorum Historia vitas ipsorum ac libros complectens,' Lond., 1709; 'Historia Typographorum aliquot Parisiensium vitas et libros complectens,' Lond., 1717; 'Annales Typographici ab artis inventæ origine ad annum 1557 (cum Appendice ad annum 1664),' Amst. and Lond., 1719-1741; 'Marmora Oxoniensa,' Lond., 1732.

MAIZE, or *Indian Corn*, is a plant commonly cultivated in the warmer parts of the world, where it answers a purpose similar to that of wheat in more northern countries. It is the *Zea Mays* of botanists, a monœcious grass, of vigorous growth, with stems not more than two feet high in some varieties, and reaching the height of eight or even ten feet in others. The leaves are broad, and hang down from large rough sheaths which surround the stem. The male flowers grow in loose, terminal, compound racemes, standing clear of the leaves: the females are arranged in numerous rows on a spike, which is wrapped round by several folds of sheathing bracts, which press upon the grains and give them the flattened figure they eventually acquire when ripe. Each grain has a long thread-like style, which projects beyond the enveloping sheaths; and as there are some hundreds of them upon each spike, the whole form a long which looks as if made of silk. The ripe grains are regularly arrayed one over the other in rows, are compressed at the sides, flattened at the apex, and of various colours. Their most common colour is pale yellow; some are white, some party-coloured, and there are varieties with blood red and even purple grains. A plant generally bears two full ears, the grains of which vary greatly in number: some of the largest ears in America contain at least 800 grains.

This plant in its wild state is met with in Paraguay, according to Auguste de St. Hilaire. It was also found on the continent of North America by the Europeans on their arrival there. A second species, called *Curagua* by Molina, is said to occur in Chili; but little is known of it further than that the leaves are serrated, and all the parts much smaller than usual.

It seems that there is a particular line on the continent of Europe north of which the maize does not thrive. To the south of this line, which passes through Nancy, formerly the capital of Lorraine in France, it has in a great measure superseded wheat and rye as the common produce of the land.. The bread made from maize is not so palatable as wheat or rye bread; but by mixing it in certain proportions with wheat it makes a very pleasant food. In the United States of North America Indian corn forms almost the only bread eaten by many of the people; and in the slave-states it is the only bread that the negroes eat. It is not however in the shape of baked bread that maize is most generally used in Europe, but in boiled messes and soups, as peas are with us: it is not only the ripe grain which is eaten, but the ear in every state, from that of a green vegetable to an unripe corn. It is boiled, stewed, and baked: it is a substitute for cabbage or green-peas in its early stage; and is used in some way or other to its complete maturity. Nothing can be better than ripe maize to fatten hogs or poultry with; and the young stem cut down quite green gives one of the best and most abundant varieties of green food for cattle.

A plant which gives such a return cannot be expected to ripen its grains in poor land, or without attentive cultivation. The land must be naturally fertile, or made so by art; it must be well prepared to receive the seed, and sufficient manure must be given to recruit it. A light, moist, and warm soil suits this plant best. It thrives well on land broken up from grass, as is the case with most plants. As it is always sown in rows, and the plants thinned to a considerable distance, the intervals may easily be ploughed, or stirred with the horse-hoe, by which means the weeds are kept down, and the earth fertilized by exposure to the air. The seed should be taken from the largest and best formed ears; those at the end should be rejected as less perfect. They should not be taken off until they are wanted for sowing, and then steeped in water to soften them. If the seed were steeped in brine and dried with quicklime, as is usually done with wheat, it might probably be advantageous, as this grain is subject to smut and brand as well as wheat: but this is not often done. The time for sowing maize in the south of France is the month of April; farther north it is sown later for fear of frost, which would entirely destroy the plant on its first appearance above ground: this is one of the reasons why it could not safely be sown in England before the middle or end of May, and it could scarcely be expected to ripen its seeds before the winter's frost set in.

The distance between the rows of maize vary from two to four feet. In good ground the latter distance has produced the heaviest crop. The seed is sometimes sown in the furrow after the plough, and sometimes put in with a dibble. The latter seems the best way, and, as the rows are wide and the seeds need not be put in nearer than a foot apart in the rows, an acre will be soon dibbled by hand. Two or three inches deep is sufficient to make the seed germinate readily. In warm moist climates the plant is very soon above ground. In fine weather, and when the seed has been steeped, it will be above ground in five or six days. When the plants are three or four inches out of the ground, and no frost is feared, they are thinned out to two feet apart, and in very rich soils three feet is better. In this case three or four ears may be expected to ripen on each stalk. In thin soils on a retentive subsoil the earth is raised in ridges, or, what is better, in mounds, by crossing the ridges with the plough, and three or four seeds are put into each hillock, which are two or three feet apart. As the plants rise, only one, or at most two are left in each hillock, and the earth is carefully moulded up to the stems; thus a deep dry bed is provided for the plant, and these draw sufficient moisture from the impervious subsoil. This method might perhaps be adopted with advantage in England, in experiments on maize where the situation admits of its cultivation. Maize, however sown, must be repeatedly hoed. At the first hoeing the plants which are too close are pulled up, and where there is a deficiency they are planted in; at least, this is the practice in Europe; but in America the general practice is to plant fresh seeds in the vacant places. When the plants are a foot high, there is a second hoeing, the weeds are then cut up, and some earth is drawn towards the plants, and raised around the stems. The reason of this is, that there are several joints very near each other at the bottom of the stem, and from each of these fibres strike out into the soil which is brought into contact with it, and form additional roots to the plant, as they do from the crown of the roots of wheat. When the flowers are ready to expand, a third hoeing is given, to kill weeds and open the surface of the soil slightly. The earth which is raised around the stems should be flattened a little at top, and even slightly hollowed out near the stem, to collect the dews and rains in dry seasons. If any tillers or suckers appear from the bottom of the stem, they should be carefully removed, as they diminish the nourishment which should go to the main stem. A fourth hoeing and earthing up at the time when the seed begins to swell, is useful, but seldom given for fear of unnecessary expense. In many countries they sow or plant various vegetables in the intervals between the rows of maize, of which the most advantageous are turnips and cabbages, which may be sown or planted between the rows, after the last hoeing. French beans, except they be dwarfs, are not so proper, as they shade the maize and prevent its maturity. In warm climates cucumbers and melons are often raised there. In Carolina, where they hoe their maize only twice, a running weed springs up rapidly called *[illegible]*, which is much relished by cattle, and is cut several times before winter.

The time of flowering is very critical for the maize; a cold damp atmosphere may make a great part of the crop fail. In situations where this is to be feared, it is safe to sow maize at several times, with a week's interval; thus the risk is divided, and it is not so likely that the whole crop will be in flower in unpropitious weather.

The male flowers, just as they expand, are excellent food for cattle; and it is usual in many places to cut off a great portion of them for this purpose. If it is done judiciously, there is no danger, provided a sufficient number of male flowers be left to impregnate the females: one in a space of about fifteen or twenty feet is thought sufficient. After the seed is set, it is customary in many places to cut off the whole top of the stem with the upper leaves, and give them to the cattle; but this is by no means to be recommended: the wound thus made bleeds, and much of the sap is lost; besides the upper leaves serve to elaborate the sap and assist its circulation; they should therefore be left on as long as they are green, and other food found for the cattle.

All plants which stand too close or have no ears upon them should be pulled up and given to the cows, to give air to the rest; all those also that are very late and have abortive ears should be taken up, as they would at all events not ripen their seed. The young ear is preserved as a pickle, like young cucumbers; when a little advanced it is roasted on the coals, or before the fire, and is pleasant to eat; in the green state, when the grains are still soft and milky, it is boiled, and used as a vegetable, and is considered a delicacy.

Maize is subject to diseases similar to those of wheat and other grains; and it is supposed, as observed before, that the steeping and liming may prevent them in a great measure.

When the maize is fully ripe, which it is not until the sheath of the ear opens and appears quite dead, the ears are broken off by hand and laid in a dry place; they are turned occasionally that the sheath may not become mouldy, and are then stored in a dry place: the seed keeps better so than when it is separated. The taking off the seeds from the cob is a laborious operation; it may be done by the flail, but is most easily accomplished by an old blunt sword or iron hoop fixed over a tub. The ears are rubbed hard over this edge and the seeds fall into the tub. They have a simple machine in America, which does the work quickly. The cobs are useful as fuel for burning in the oven. The leaves are gathered for fodder a short time before the ears are pulled. In America and in Italy they stuff mattresses with the dry sheath, which makes a cool and elastic bed.

All animals are fond of maize, especially horses, pigs, and poultry; it gives the flesh of the last a peculiarly fine flavour. The most profitable way to use maize in fattening animals is to grind it into meal, and mix it with warm water into a porridge; and, for horses, to soak it twenty-four hours in water before they are fed with it. In the dry state it is so hard that it wears their teeth, and in young horses is apt to produce blindness, by the exertion of the muscles of the jaw in chewing it.

One of the most important uses of maize in Europe is to sow it thick, to be cut green as food for cows, oxen, and sheep. In a proper climate there is no plant which gives so great a mass of green food as maize. The produce is most abundant and nutritive. The largest varieties should be chosen. The seed may be sown in drills in April, and in September a crop might be mown, which would give admirable fodder for every kind of cattle. It is said to exhaust the land; but what will not exhaust it, more or less, which gives much nourishment? Maize will well repay the manure which may be required to restore the humus that it has consumed. If it is sown early a second crop may be raised the same year; for it does not spring up again, like grass, after being cut. Where the land admits of irrigation, the growth of the maize is most rapid and luxuriant. The time to cut it is when the male flowers are just appearing out of the sheath in which they are enveloped in the early stage of their growth. It may be dried into hay, and will keep good for a couple of years; but in this state it must be bruised or soaked when given to cattle, as the stems get very hard in drying; they may however be cut, as the cane-tops are in the sugar-plantations.

MAJOR (Latin), *Greater*, in music, a term applicable to the imperfect concords, but chiefly to the interval of the 3rd. It is also used to distinguish the mode which takes a major or sharp 3rd, from that having a minor or flat one. The major mode has always a greater 3rd—*i.e.* a 3rd consisting of two tones; and the minor mode has always a minor 3rd—*i.e.* a 3rd consisting of a tone and a semitone. [KEY; MODE; THIRD.]

MAJOR, a field-officer next in rank below a lieutenant-colonel, and immediately superior to the captains of troops in a regiment of cavalry, or to the captains of companies in a battalion of infantry. His duty is to superintend the exercises of the regiment or battalion, and on parade or in action, to carry into effect the orders of the colonel. The major has also to regulate the distribution of the officers and men for the performance of any particular service; and he has a temporary charge of the effects appertaining to any individual of the corps, in the event of the absence or death of such individual.

This class of field-officers does not appear to have existed before the beginning of the seventeenth century; and, at first, such officers had the title of *serjeants-major*, a designation borne at an earlier time by a class corresponding to that of the present majors-general of an army. (Grose, vol. i., p. 244.)

No mention is made of either lieutenant-colonel or major, as field-officers, in the account of Queen Elizabeth's army in Ireland (1600). But Ward, in his *Animadversions of Warre* (1639), has given a description of the duties of the latter class, under the name of serjeants-major, from which it appears that these duties were then nearly the same as are exercised by the present majors of regiments. They are stated to consist in receiving the orders from the general commanding the army; in conveying them to the colonel of the regiment, and subsequently in transmitting them to the officers of the companies; also, in superintending the distribution of ammunition to the troops, and in visiting the guard by day or night.

A *brigade-major* is a staff-officer who performs, for a brigade, or in a garrison, duties corresponding to those of a major in a regiment or battalion.

The prices of a major's commission are:—

In the Life and Royal Horse Guards	£5350	daily pay	£1	4	0.
In the Dragoons	4575	„	0	19	3.
In the Foot Guards (with the rank of colonel)	8300	„	1	6	9.
In the regiments of the line	3200	„	0	16	0.

A serjeant-major of a regiment is a non-commissioned officer, who in general superintends the military exercises of the soldiers: on parade, he has the care of dressing the line.

MAJOR-GENERAL. [GENERAL.]

MAJOR, or MAIR, JOHN, was born at the village of Cleghorn, near North Berwick, in East Lothian, about the year 1470. He appears to have studied for a short time both at Oxford and Cambridge, but he always regarded the university of Paris as his true *alma mater*, whither he proceeded in 1493, and where he attached himself successively to the colleges of St. Barbe, of Montaigu, and of Navarre. Having been made a doctor of the Sorbonne in 1505, he betook himself to the teaching of the scholastic philosophy, or divinity, in the college of Montaigu, and in this department soon came to be reputed one of the most distinguished ornaments of the university. Mair's scholastic writings indeed have been rated by Dupin and others in later times as the ablest that have come down to us from that age.

In 1519 he returned to his native country, and officiated for some time as one of the regents or masters in St. Salvator's college, St. Andrew's; but a dispute with some of his colleagues soon induced him to go back to Paris, and there he remained till 1530, when he was induced once more to transfer himself to St. Andrew's, which he never afterwards left. He became eventually provost or principal of St. Salvator's college, and appears to have died in that office about the year 1550.

Major's works are all in Latin, and the principal are Commentaries on the Four Books of Sentences, some theological expositions and commentaries on parts of the Scripture, and his History of Scotland, entitled 'De Historia Gentis Scotorum, seu Historia Majoris Britanniæ,' first printed in 4to. at Paris, in 1521. The style of all his writings is careless and inelegant to barbarism; but his History appears to have the merit of being a faithful enough chronicle of events, so far as he knew them. It is however as little marked by any spirit of critical or profound research as by classical purity of diction. Both this and some of his philosophical writings are remarkable for a freedom of sentiment upon points both of civil and ecclesiastical government, which he is believed to have derived from his teachers Jean Gerson and Pierre d'Ailly, and to have communicated to his famous pupils Buchanan and Knox. Dr. MacCrie, in his 'Life of Knox,' Edinb., 1813 (vol.., p. 345), has given some extracts from Major's works, which evince the liberal complexion of his opinions. The well known epigram of Buchanan however, in which he designates him 'Solo cognomine Major,' testifies that the great scholar and wit had no very high opinion of the intellectual endowments of his old master.

MAJORCA. [MALLORCA.]

MAKRI. [ANATOLIA.]

MAKRIZI (or, with his full name, Takki-eddin Abu-Mohammed Abul-Abbas Ahmed Almakrizi), a celebrated Arabic writer, was born at Cairo between A.D. 1358 and 1368. His family originally lived in one of the suburbs of Baalbec, called Makriz, whence he derived the surname by which he is usually known. We have very few particulars of his life; but it appears that he resided at Cairo, during the greater part, if not the whole of his life, that he discharged at different times the duties of several public offices, and that he died, at an advanced age, in A.D. 1442.

Makrizi wrote several historical works; of which copious extracts are given in De Sacy's Arabic Chrestomathy. The most important of these works is his 'Description of Egypt;' which gives an account of the history of the country from its conquest by the Mohammedans, as well as a description of its natural history and antiquities, and of the manners and customs of the inhabitants. De Sacy, in his notes added to his translation of Abd-Allatif, published under the title of *Relation de l'Egypte*, Paris, 1810, has made many interesting quotations from the work of Makrizi.

The only works of Makrizi which have been printed are, as far as we are aware: 'Historia Monetæ Arabicæ,' in Arabic and Latin, by Tychsen, Rostock, 1797, of which a French translation, much superior to the Latin one by Tychsen, was published by De Sacy, under the title of 'Traité des Monnoies Musulmanes,' Paris, 1797; 'An account of the Mohammedan Princes in Abyssinia,' by Rink, Leyd., 1797; 'Narratio de Expeditionibus à Græcis Francisque adversus Dimyatham ab A.C. 708 ad 1221 susceptis,' in Arabic and Latin, by Hamaker, Amst., 182[illegible]; 'Historia Coptorum Christianorum in Ægypto,' Arabic and Latin, by Wetzer, 1828.

MALABAR, a province of Southern India, lying between 10° 20′ and 12° 20′ N. lat., and between 75° 1[illegible]′ and 76° 55′ E. long. Its greatest length from north to south is 118 miles, and its breadth does not in any part exceed [illegible] miles: its area is about 7250 square miles. It is bounded on the north by Canara; on the east by Coorg, Wynaad, and Coimbatore; on the south by the territory of the Cochin rajah; and on the west by the Indian Ocean.

As to its general features, Malabar may be divided into two portions. One of these, which is by far the most extensive, consists of low hills separated by narrow valleys. The hills have in general steep sides and level summits; the best soil is on the sides, and, to prevent this being washed away, the surface is formed into a series of terraces. The summits of many of the hills are bare, especially towards the north, where they exhibit little besides naked rock. The soil in the valleys has been washed down in the course of ages from the hills, and is extremely fertile. The other portion of the province consists of a level plain or belt along the coast, seldom more than three miles wide, and often not so much. The soil is sandy and poor, but being intersected by numerous mountain-streams, it is well adapted for the cultivation of rice. The whole of the province lies immediately below the western ghauts.

The pepper-vine grows most abundantly along the whole coast-line of Malabar, and its produce forms the chief article of export from the province. A great part of it is sent to Europe, but large quantities are also exported to China, or conveyed by native traders to Arabia and the north-west countries of India. Sandal-wood, which is another principal article of export from Malabar, is not produced within the province, but is brought from above the western ghauts. Jaggry, a coarse kind of sugar, is made in large quantities from a species of palm, the *brab-palm*, and is commonly sold at a very low price, less than [illegible] shillings per hundredweight. Part of the coast is covered with thick forests of cocoa-nut trees, from the produce of which a revenue is drawn by the government.

The province is divided for the purposes of internal government into 2212 villages, which do not however consist, as in most other parts of India, of aggregations of houses, but rather of territorial divisions answering more to our parishes. The dwellings of the natives are for the most part scattered over the face of the country. Almost the only collections of houses are found in the seaports. The principal of these are Tellicherry, Mahé, and Calicut. [CALICUT.] Tellicherry is in 11° 45 N. lat. and 75[illegible] E. long. In 1683 a factory was established there by the presidency of Surat, for the purchase of pepper and cardamom seeds. It is still the residence of the richest native merchants, and is the principal market for the sandal wood brought from the interior; but a great part of the export trade has of late years centred at Mahé, a small town and port about five miles to the southward, which was settled by the French in 1722.

Malabar is one of the few parts of Hindustan in which the ownership of the soil is recognised as belonging to individuals, and not to the supreme government. Landed property is held in this province, as well as in Canara, Cochin, Travancore, and Bednore, on tenures which from time immemorial have never been questioned. It might be more correct to say that the English government has not committed the same error with regard to those provinces as it has in other parts of India, that of considering the property in the land to belong to the state. The succession to lands in Malabar follows the same rules as those that regulate succession to other kinds of property.

The population consisted almost wholly of Hindus until the invasion of Hyder Ali in 1760, since which time there has been an accession of *Moplays* (Mohammedans), Christians, and Jews, but not in considerable numbers. Among the Hindu population the distinctions of caste are kept up with the greatest scrupulosity. The distances within which an individual of an inferior may not approach one of a superior caste are accurately defined. The distinctive names of the castes are—1st, Namburies or Brahmins; 2nd, Nairs or Sudras; 3rd, Tiars, who are free cultivators of the land; 4th, Malears, who are musicians and conjurors (these are free also); 5th, Poliars; these are slaves, and are properly below all caste; but there is an outcast while inferior even to those called Nialis. There are several subdivisions of the first three castes. The Poliars are bought and sold like cattle, either with or separate from the land, one of them being generally reckoned of equal value to two buffaloes. They are often treated with severity, and are of a miserable appearance, squalid, and diminutive.

The whole province was subdued in 1760 and 1761 by Hyder, and in 1783 it was overrun by Tippoo, and the rajahs were mostly driven for refuge to Cochin and Travancore, but in 1790 were reinstated by the English government, under whose superintendence the affairs of the province have much improved, the revenues have been augmented, and the trade increased. The province is under the immediate superintendence of the governor of Madras.

MALABAR LANGUAGE. [HINDOSTAN, p. 203.]

MA'LABATHRUM, a name which occurs frequently among the writings of the ancients, and which was applied to a leaf imported from India, whence it was likewise called φύλλον Ἰνδικόν, and also simply Folium. It was employed by them both as a medicine and as a perfume. From it there was prepared both an oil and a wine by maceration of the leaves in these menstrua. Many fabulous statements accompany the earliest accounts, as that of Dioscorides, by whom it is stated that by some they are thought to be the leaves of the Indian Nard; that they are moreover found floating on Indian marshes, and that they grow without roots (lib. i., c. 11), and that (lib. ii., c. 10) it is by feeding on them that the animal affording the onychos, or unguis odoratus of the ancients, becomes aromatic. In the works of the Arabs *sadaj* is given as the synonyme of Malabathrum; and *sadaj*, both in Persian works and in India, is applied to tej-pat, or the leaf of the *tej*, which is a species of Cinnamomum, *C. albiflorum*, growing in the dense forests of the valleys of the Himalaya, which extend from Rungpore to the Deyra Doon in 30° N. lat. Dr. Hamilton found the same name applied to a very nearly allied species, the *C. Tamala*. Both species most probably yield the leaves which were so highly esteemed in ancient times, and are still as extensively employed in eastern countries, and may be found in every Indian bazaar under the names of *tuj* or *tej-pat*, or by the Arabic name of *sadaj-hindee*. They are analogous in all respects to bay-leaves produced by the Laurus nobilis, and are in fact the bay-leaves of India. The name Malabathrum no doubt is derived from *Tamala-patra*, or Tamala-leaf, as was first indicated by Garcias: 'Appellant autem Indi Folium Tamalapatra quam vocem Græci et Latini imitantes corrupte Malabathrum nuncuparunt.' These are brought from the interior of almost inaccessible forests, and necessarily stripped from the branches for the facility of carriage; hence most probably originated the fables with which their early accounts are accompanied.

MALACCA, a town in Southern Asia, situated on the western coast of the Malay Peninsula, in 2° 14′ N. lat. and 102° 12′ E. long., on the straits called by its name. It is on the northern banks of a small river. The roads along the shores are good and safe. South of the town there is a small island, between which and the continent is a harbour, where, during the south-west monsoon, vessels not drawing more than 16 feet water are secure. The bar at the mouth of the river has only water enough during high tide for boats. Many of the houses are tolerably well built, but the greatest part, which are inhabited by Asiatics, are composed of bamboo and mat huts. On the southern side of the river are the ruins of a fort, now converted into a public promenade.

Malacca was built in 1252, by Sri Iscander Shah, the king of the Malays, after his expulsion from Singapura, a town situated on or near the site of the emporium now called Singapore. It was first visited by the Portuguese in 1507, and taken by Alfonso Albuquerque in 1511. It was then a large commercial town, and the harbour contained 300 vessels. It continued in a flourishing condition till 1640, when it was taken from the Portuguese by the Dutch, upon which event its commerce began to decline, being partly transferred to Batavia. But its position on the great thoroughfare between the Gulf of Bengal on one side and the Indian Archipelago and China still gave it some importance; though the establishment of a British colony in the island of Pulo Penang, in 1786, diminished its commerce. It was taken possession of by the British in 1795, restored at the peace of Amiens, but soon afterwards taken again. In 1818 the Dutch recovered possession of it; but the British having founded the town of Singapore in 1819, which in a few years became a great commercial place, Malacca sunk to insignificance. The town and fort of Malacca, with its dependencies, were ceded to the English by the treaty between the Britannic and Netherland governments of March, 1824.

Besides the town, this colony consists of a tract of country about 40 miles long and 30 miles wide; its surface may be about 1000 square miles. The country along the sea-coast, to the distance of 12 or 15 miles, is low and nearly level, in many parts swampy, and mostly covered with wood. The soil is not distinguished by fertility; and though rice is raised, this article, as well as other grain, is annually imported from Bengal. Fruits succeed exceedingly well, as pine-apples, shaddocks, oranges, &c. Cocoa-nut palms are numerous. The cultivation of coffee has been introduced lately. Pepper is grown in a considerable amount, and 4000 piculs (1 picul = 133⅓ pounds) are annually exported. The amount of tin annually got from the mines is estimated at 3000 piculs. There is also gold.

The bulk of the population consists of Malays. There are some Hindus and Chinese, and also some descendants of the Portuguese and Dutch. In 1822 the population in the town of Malacca amounted to 12,000 souls, and in the whole colony to 22,000. After the British got possession of it, the number decreased by emigration to Singapore, but the population has recently begun to increase, and is said to be 30,000.

(Crawfurd's *Journal of an Embassy to the Courts of Siam and Cochin China*; Finlayson's *Journal of a Mission to Siam and Hué*; *Notices of the Indian Archipelago, &c.*, collected by J. H. Moor, Singapore, 1837. [NANKING.]

MALACCA, THE STRAITS OF, separate the Malay Peninsula from the island of Sumatra. They begin on the north between Diamond Point on Sumatra and the island of Pulo Penang near the shores of the continent, about 5° 20′ N. lat., and terminate on the south between the most southern cape of the Asiatic continent, the Tanjung Burus (1° 15′ N. lat.), and the islands of Carimon or Krimon (1° N. lat.). Its direction is from north-west to south-east, between 97° 30′ and 103° 40′ E. long. At its northern extremity it is nearly 180 miles wide, but southward it grows narrower, and opposite the town of Malacca, from which it takes its name, the strait is hardly 36 miles wide, and both shores are visible from the middle of the channel, though they are rather low. The strait preserves this width to its southern extremity. Being enclosed on the south-west and north-east by countries in which the mountain-ranges rise to a great elevation, this strait is not subject to the violence of the south-west and north-east monsoons, and the sea, especially at its southern extremity, is always as smooth as a pond. But when the Gulf of Bengal is agitated by the strong gales of the north-west monsoon, there is a heavy sea in the northern and more open portion of the strait, which at that time inundates many parts of the low shores which are immediately contiguous. The countries bordering on the strait have not the periodical seasons of rain and dry weather, but rain occurs the whole year round, and mitigates the heat of the atmosphere. Perhaps in no part of the globe is the temperature of the air less subject to changes than on these shores.

(Finlayson's *Journal of a Mission to Siam and Hué*; and Crawfurd's *Journal of an Embassy to the Courts of Siam and Cochin China*.)

MA'LACHI (מַלְאָכִי, 'my messenger'), the last of the twelve minor Hebrew prophets. So completely are we ignorant of the personal history of this prophet, that it has been doubted whether 'Malachi' is the name of a person, or only a title descriptive of the prophetic office. In the absence of any positive proof of the latter supposition, the former must be adopted as the more natural. Many of those who believe that 'Malachi' is an official title identify the prophet with Ezra. This was the opinion of Jerome.

Malachi evidently prophesied after the Babylonish captivity. He was later than Haggai and Zechariah, for he does not, like them, exhort the people to zeal in rebuilding the Temple, but he refers to it as already built (i. 7, 10; iii. 1, 10). In chap. i., ver. 8, he speaks of a political ruler of the people; now, no one appears to have held such an office later than Nehemiah, after whose time political power was in the hands of the priests. Moreover the state of things described and reproved in this prophecy agrees with the account which Nehemiah gives of the manners of the people after his second return from Persia into Judæa. (Compare *Mal.* ii. 8-11, with *Nehem.* xiii. 23-29; *Mal.* iii. 8, 10, and *Nehem.* xiii. 5, 12 x. 38, 39, with *Nehem.* xiii. 6-13; *Mal.* i. 8, 11, 13, ii. 8, with *Nehem.* xiii. 15, &c.) Hence Vitringa and others have concluded that Malachi prophesied during the latter part of Nehemiah's administration (about B.C. 432 or 420).

The object of this prophecy is to reprove the people and the priests for their irreligion. To the complaint of the people, that God dealt unkindly with them, the prophet replies by comparing their prosperity with the calamities that had befallen the Edomites (i. 2-5). He reproves the priests for their dislike to the service of God, their unholy sacrifices, and their perversions of the law, and the people for their intermarriages with the neighbouring heathen nations (i. 6, to ii. 16). Before the Captivity idolatry had been the great sin of the Jews, but now they seem to have been prone to infidelity, complaining that the wicked were favoured by God, and that the Messiah did not appear. The prophet therefore announces the approach first of the Messiah's precursor, and then of the Messiah himself, whom he styles 'the messenger of the covenant,' to purify the people of God, and to punish the ungodly (ii. 17, to iii. 6). He points to the withholding of tithes and offerings as the cause of the barrenness of the land, and promises a return of plenty upon the payment of these dues (iii. 7-12). He again answers the infidel complaints of the people by referring to a future recompense, and predicts the coming of Elijah to bring the people to repentance, denouncing a curse upon the land if they despised his ministry (iii. 13, to the end). This part of the prophecy is applied in the New Testament to John the Baptist. (Compare *Mal.* iii. 1, with *Matt.* xi. 10, *Mark*, i. 2, *Luke*, i. 76, vii. 27; and *Mal.* iv. 5, 6, with *Matt.* xi. 14, xvii. 10-13, *Mark*, ix. 11-13, *Luke*, i. 17.)

The prophecy of Malachi is almost entirely in prose. His style has the vigour which belongs to an indignant censor of abuses, but he is deficient in the poetical beauties of the earlier prophets. Bishop Lowth remarks that 'the book is written in a kind of middle style, which seems to indicate that the Hebrew poetry from the time of the Babylonish captivity was in a declining state, and being past its prime and vigour, was then fast verging towards the debility of age.' (*Prælec.*, xxi.) The canonical authority of this book is not disputed.

(Rosenmüller's *Scholia;* the Introductions of Eichhorn, De Wette, Jahn, and Horne.)

MALACO'LAPHUS. [WOODPECKERS.]

MALACO'LOGY. The science of molluscous or soft-bodied animals (Μαλακὸς and λόγος[*]) includes the knowledge of such animals, whether protected by shells or entirely naked, and their distribution into classes, subclasses, families, genera, and species. In this more extended and philosophical view of the subject, *conchology* may now be considered as merged; and the more modern classifications are based upon the anatomy of the soft parts and the habits of the animals, as well as upon the structure of the shells in those molluscous forms which have that protection. In the article CONCHOLOGY will be found a short statement of the reasons for treating the subject under the present title.

The shell-collector of former days looked upon his drawers, if they were rich in rare species or varieties, as containing an assemblage of gems; and indeed the enormous prices given for fine and scarce shells, joined with the surpassing beauty of the objects themselves, almost justified the view which the possessor took of his cabinet of treasures. They were to him really 'Les Delices des Yeux et de l'Esprit;[†] and the energetic zeal with which he collected and the sacrifices that he made to procure a fine and perfect *Many-ribbed Harp*, a *Gloria Maris*, or *Cedo Nulli*, among the cones; an *Aurora* or *Orange-Cowry*, a *Voluta aulica* or *Voluta Junonia*, &c., were only comparable to the extravagances of those visited by the tulip mania when it was at its height. But though they were the delight of his eyes, they were, in nine cases out of ten, little more to the owner of them: they were mere trinkets on which he looked dotingly without knowing, and scarcely wishing to know, the organization of the animal whose *skeleton* only was before him. This innocent trifling came at last to be viewed in its true light by some collectors worthy of better employment, who put off childish things and went deeper into the subject. Lister, Adanson, Linnæus, Poli, Cuvier, Lamarck, De Blainville, and others gave dignity to this department of zoology, and gradually raised the science to its proper rank; whilst the comparatively imperishable nature of the covering of the testaceous mollusks became, in the hands of such men as William Smith and his followers, among the most valuable records by which the stratification of the earth's crust could be demonstrated and its geological history deciphered. [GEOLOGY, vol. xi., p. 131.)

We must first examine what animals are included under the general name of *Mollusca*, or, if M. de Blainville's term be adopted as being the more comprehensive, *Malacozoa* or *Malacozoaria*.

The Μαλάκια of Aristotle, his Ὄστρεα or Ὀστρακόδερμα, and his Μαλακόστρακα, are distinguished by him from the fishes as not having, like the latter, blood; which must be understood as meaning that they were without red blood. The Μαλάκια are further described as having all the fleshy parts external and the solid or firm parts internal, and are thus distinguished from the Ὀστρακόδερμα, which are defined as having the fleshy parts internal and the solid parts external. The Μαλακόστρακα are described as also having the solid parts of their bodies external, and the soft and fleshy parts internal, but as being protected externally by a *crust* instead of a *shell*, and having ambulatory feet.

Thus the Μαλάκια and Ὀστρακόδερμα of Aristotle, who is followed by Ælian and the Greek naturalists generally, correspond with the *Naked* and *Testaceous Mollusca* of the moderns.

Pliny and the antient Latin zoologists employ the same denominations as the Greeks, though they have translated them by the terms *Mollia* for the *Naked*, and *Testacea* for the *Shell-protected* Mollusks.

Upon the revival of letters, we find Belon, Rondelet, Gesner, and Aldrovandus adopting the denominations of the antients, and Jonston, in his general compilation, continuing the same under the general terms of *Exanguia* or *Exanguia aquatica;* and the more particular ones, as applicable to the animals immediately under consideration, of *Mollia* or *Mollusca* and *Testacea* or *Conchylia*.

Our countryman John Ray, who has justly been called the Precursor of Linnæus, and whose systematic views on the subject of zoology are well worthy of the attention of the student, appears to have been the first who applied the term *Vermes* or *Worms* to all invertebrate animals (with the exception of Insects and Crustaceans), whose blood or circulating fluid is white, and who employed the term *Vermes* (*Mollusca*) and *Vermes* (*Testacea*) to denote the divisions of Aristotle.

Lister, in his 'Synopsis Methodica Conchyliorum,' cannot be considered as having done much as a systematist, and though that zoologist gave the anatomy of many molluscous animals, as had been done by Fabius Columna before him, and Willis, Swammerdam, and others after him, little appears to have been effected for a principle of classification resting on their external organization or their form, and still less for one resting on their internal structure.

Linnæus, in his 'Natural Division' of Animals into three sections, depending on the structure of the heart and on the circulating fluid, makes his third section consist of those animals which have an unilocular heart without an auricle (inauritum), and a white and cold circulating fluid (sanie frigida, albida). This section he separates into two subdivisions: the first (Antennata) consisting of the *Insects* (Insecta); the second consisting of the *Worms* (Vermes).

The following is his definition of his 'Class' *Vermes*, *Cor* (Heart) uniloculare, inauritum, sanie frigida. *Spiracula* (Respiratory organs) obscura. *Maxillæ* (Jaws) multifariæ, variæ variis. *Penes* (Intromissive generative organs) varii Hermaphroditis Androgynis. *Sensus* (Organs of Sensation) Tentacula (Caput nullum, vix oculi, non aures, Nares). *Tegmenta* (Covering or Integument) calcarea aut nulla, nisi spinæ. *Fulcra* (Organs of support or motion). Nulli pedes aut pinnæ.

The class so defined—and the very definitions will show how very limited the knowledge of the structure of such animals was in the time of the writer—consists of the following orders in the *Systema Naturæ*:—1. *Intestina*. 2. *Mollusca*. 3. *Testacea*. 4. *Lithophyta*. 5. *Zoophyta*.

---

[*] M. de Blainville, who first proposed the term *Malacozoologie*, or by abbreviation *Malacologie*, makes the etymology μαλακὸς, soft, ζῶον, animal, and λόγος.

[†] The French title of Knorr's celebrated work in German and French. The German title is 'Vergnügen der Augen und des Gemüths,' 4to., Nuremberg, 1757, 1764

The order *Mollusca* consists of the following genera arranged in the subdivisions here given:—

MOLLUSCA.

α. *Mouth above. Animal fixing itself by its base.*

Actinia. Ascidia.

β. *Mouth anterior. Body perforated with a small lateral foramen.*

Limax. Aplysia. Doris. Tethis or Tethys.

γ. *Mouth anterior. Body surrounded anteriorly by Tentacles.*

Holothuria. Terebella.

δ. *Mouth anterior. Body brachiated, or furnished with arms.*

Triton. Sepia. Clio. Lernæa. Scyllæa.

ε. *Mouth anterior. Body pedated.*

Aphrodita. Nereis.

ζ. *Mouth below, central.*

Medusa. Asteria or Asterias. Echinus.

In the above assemblage of animals we find a very heterogeneous arrangement; *Mollusca*, *Radiata*, and the genus *Lernæa* (which last the best authorities consider to be Crustaceous), being there collected together.

The order *Testacea*, 'Testaceous simple mollusks, covered with a calcareous shell,' consists of the following subdivisions and genera:—

TESTACEA.

* *Multivalvia.*

Chiton (*Animal* Doris). Lepas (*Animal* Triton). Pholas (*Animal* Ascidia).

* * *Bivalvia*: CONCHÆ.

Mya (*Animal* Ascidia). Solen (*Animal* Ascidia). Tellina (*Animal* Tethys). Cardium (*Animal* Tethys). Mactra (*Animal* Tethys). Donax (*Animal* Tethys). Venus (*Animal* Tethys). Spondylus (*Animal* Tethys). Chama (*Animal* Tethys). Arca (*Animal* Tethys?). Ostrea (*Animal* Tethys). Anomia (*Animal* Corpus Ligula, *emarginato, ciliato, ciliis valvulæ superiori affixis.* Brachiis 2, *linearibus, corpore longioribus, conniventibus, porrectis, valvulæ alternis, utrinque ciliatis, ciliis affixis valvulis utrisque*). Mytilus (*Animal* Ascidia?). Pinna (*Animal* Limax).

* * * *Univalvia Spira regulari*: COCHLEÆ.

Argonauta (*Animal* Sepia). Nautilus (*Animal—Rumph. Mus.*, t. 17, f. D). Conus (*Animal* Limax). Cypræa (*Animal* Limax). Bulla (*Animal* Limax). Voluta (*Animal* Limax). Buccinum (*Animal* Limax). Strombus (*Animal* Limax). Murex (*Animal* Limax). Trochus (*Animal* Limax). Turbo (*Animal* Limax). Helix (*Animal* Limax). Nerita (*Animal* Limax). Haliotis (*Animal* Limax).

* * * * *Univalvia absque spira regulari.*

Patella (*Animal* Limax). Dentalium (*Animal* Terebella). Serpula (*Animal* Terebella). Teredo (*Animal* Terebella). Sabella (*Animal* Nereis).

This arrangement makes each of the generic characters reside in the shell, which is treated as the habitation of the 'animal.' Any one who examined this method soon found that it was impossible to affix any definite idea to many of the inhabiting animals; and but a vague one to most. To the bulk of the *Bivalves* or *Conchæ*, a *Tethys* is assigned as the animal; to the bulk of the *Univalves with a regular spire*, a *Limax* or Slug, which last is stated to be the animal of *Pinna* among the *Bivalves*; and yet the wonder is how Linnæus approached so nearly to a natural arrangement with the scanty materials—for scanty they were when compared with the information that we now possess—which formed the groundwork of his classification. Upon this system almost all scientific collections of *Shells* were arranged till within these few years; and so bigoted were many of the followers of this great man, who would have been the first to remodel his arrangement as new light poured in upon him, that every attempt at adopting the views of Cuvier, Lamarck, and others, and even those of Bruguière, founded upon the structure of the animals, was for a long time resisted, and almost resented as a presumptuous attempt at 'genus-making.'

Daubenton had read to the Academy of Sciences at Paris a memoir on the systematic distribution of *Shells*, in which, whilst he admitted that an acquaintance with these alone might suffice for arrangement, he remarked that a knowledge of the animals, or soft parts, was indispensable for forming a complete system of conchology and a natural distribution of these *genera*. But though this indefatigable anatomist broached this opinion, he does not appear to have carried his plan into execution.

Guettard seems to have been the first who carried out the suggestion of Daubenton; for in 1756 he read a memoir inserted in the 'Transactions' of the same Academy, and therein established upon sound principles the necessity, in forming a classification of shells, of having recourse to the animals, or soft parts which they enclose, and a part of which the shells are. He did more; for he well characterised, upon the principle advocated by him, several genera, especially among the *Univalves*, as they were then called. And although he acknowledges that his information with regard to the *Bivalves* was not sufficient to enable him to carry out his views in the same manner with regard to them, he observes that they must be susceptible of being characterised with reference to the animals, or soft parts, as well as the Bivalves. Guettard further pointed out the division of shells into *Terrestrial*, *Fluviatile*, and *Marine*, and paid particular attention to the presence or absence of the *operculum*. There can be little doubt that these observations determined d'Argenville to add to his second edition of 'Conchyliologie' (1757) a number of figures of the animals, or soft parts, under the name of *Zoomorphoses*; these, it is true, are many, if not all of them, very bad.

The principles of Guettard were in the same year (1757) more extensively applied by Adanson in his 'Histoire Naturelle du Sénégal—*Coquillages*.' He distinguishes all the external parts of the animals and the shells. In the *Univalve Shells*, as they were then called, or, as Adanson denominates them, the *Limaçons*, he points out the whorls (spires), the apex (sommet), the aperture, the operculum, &c.; and in the Bivalves, under the name of *Conques*, he treats of the valves, which he terms battans, and notices their equality or inequality—whether they shut close or gape at any point—the hinge, and the number and form of the teeth composing it, with the cavities which they form—the ligament, considering it as to form and situation—the muscles, or rather muscular impressions with regard to their figure, size, and number; the nacre, &c. Out of the modifications of these parts of the bivalve shell he forms divisions—as five depending on the variations of the hinge; three depending upon the relative situations of the ligament externally, internally, &c.; three depending upon the modifications of muscular attachment, viz. *Conques* with one muscular attachment, *Conques* with two muscular attachments, and *Conques* with three muscular attachments; and three depending upon the presence or absence of the nacre and its modifications.

In the animals, or soft parts, of the *Limaçons*, he directs his attention to five principal parts.

1. The *tentacula*, or tentacles, which he names horns (cornes), and which he considers with regard to their number and shape as furnishing specific character, according as they are absent, or as there are two or four, or according to their conical or cylindrical form, the absence or presence of convexity (renflement) at their origin, and their situation at the root, or at the extremity of the head.

2. The *eyes*—their absence or presence; and in the latter case, their situation upon the head at the internal side of the root of the tentacles, behind the tentacles, towards their internal side, at the origin of the tentacles on their external side, above the root of the tentacles on their external side, at the middle of the tentacles on their external side, and at the summit of the tentacles.

3. The *mouth*, as provided with two jaws without a proboscis, or with a proboscis without jaws.

4. The *trachea*, or respiratory orifice, as formed by a simple hole situated on one of the sides of the animal, or by a long pipe which has its exit near the back.

5. The *foot*, according as it is divided by a transverse furrow at its anterior part, or not.

The *Conques* are regarded by Adanson with reference to four principal parts, viz.:

1. The mantle, which may be either divided all round into two lobes, or divided on one side only, or form a sac, open only at the two opposite extremities.

2. The trachea, or tube, which may be either single, and in the form of an aperture, double in the form of apertures, double in the form of separate and distinct pipes, or double in the form of united pipes.

3. The foot null, or not appearing externally, or appearing externally.

4. The byssus, or threads, which exist in some species, and do not exist in others.

The shells which he had observed at Senegal are figured and distributed generally in the following order, under two families

Family 1.

LIMAÇONS.

§ I.

Limaçons Univalves.

Genera:—Cymbium. Bulinus (Physa of the moderns). Coretus (Planorbis of Guettard). Pedipes (Auricula of Lamarck). Cochlea (Bulimus of Bruguière). Lepas (Patella of modern authors and also embracing the Chitons). Haliotis. Yetus (Voluta of Lamarck, Cymba of Broderip). Terebra. Porcellana (Marginella and Oliva of authors). Cypræa. Peribolus (Young of Cypræa and small Marginellæ).

§ II.

Limaçons Operculés.

Strombus (Conus of the moderns). Purpura (including, with the true Purpuræ, Dolium, Cassidaria, Murex, Strombus of the moderns, some Mitræ, &c.). Buccinum. Cerithium. Vermetus. Trochus. Turbo. Natica. Nerita.

The *Conques* are also divided into two sections.

§ I.

Conques Bivalves.

Genera:—Ostreum (Ostrea of the moderns). Jataronus (Spondylus? of the moderns). Perna (including Mytilus, Modiola, Avicula, Pinna, and Cardita). Chama (including Venus, Cytherea, Mactra, Cardita, and some of Solen; but apparently none of the Chamæ of modern authors). Tellina (Donax of the moderns). Pectunculus (including Cardium, Arca, and some true Pectunculi of Lamarck). Solen.

§ II.

Conques Multivalves.

Pholas. Teredo.

Such is the system of Adanson; and although it presents errors, which would very probably have been avoided by so good an observer, if he had lived at a later period, when this branch of knowledge became better known, we must allow him the merit of being the first who practically applied the principle of classification based on the structure of the soft as well as the hard parts, or, in other words, on the organization of the animal and shell.

Geoffroy, a physician of Paris, applied the same principle to his little 'Treatise on the Terrestrial and Fluviatile Shells' in the neighbourhood of that city. His genera of Univalves amount to five only, viz. *Ancylus*, *Cochlea*, *Buccinum*, *Planorbis*, and *Nerita*. His genera of Bivalves consist of two, *Chama* and *Mytilus*; in the first of which he places *Cyclas*, and in the second an *Anodon* and a *Unio*.

Müller, the Dane, presented zoologists with a system founded on the same principle, which, whilst it was more complete than that of Guettard, inasmuch as it extended to all conchyliferous animals, was less natural than that of Adanson, and altogether inferior to it, as far as Adanson's went; but it was much more elaborate, and demands a great share of praise. The author of the *Zoologia Danica*, in his 'Vermium terrestrium et fluviatilium Historia,' adopts three primary divisions—*Univalves*, *Bivalves*, and *Multivalves*.

He divides the *Univalves* into three sections:—

1. Those testaceous univalves whose shell is pierced through and through; and in this section he places the *Echini* and *Dentalium*.

2. Those which have a very large aperture, consisting of *Akera* (*Bulla* of modern zoologists), *Argonauta*, *Bulla* (*Physa* of Draparnaud and others), *Buccinum* (*Limnæa* of the moderns), *Carychium*, *Vertigo*, *Turbo*, *Helix*, *Planorbis*, *Ancylus*, *Patella*, and *Haliotis*.

3. Operculated testaceous univalves, in which he places the genera *Tritonium* (*Buccinum* of Linnæus), *Trochus*, *Nerita*, *Valvata*, and *Serpula*.

The *Bivalves* are divided by the same author into two sections only: the 1st consisting of those which have a toothed hinge, including *Terebratula*, a new genus; the 2nd, of those which have a toothless hinge, including two new genera, *Anomia* and *Pecten*, which he separates from the oysters.

The *Multivalves* comprise the genera *Chiton*, *Lepas*, and *Pholas*.

There can be little doubt that it was to these authors (among whom we do not include Müller, whose works appeared subsequently, nor Geoffroy, whose treatise appeared nearly simultaneously) we owe the amended arrangement of Linnæus as it finally appeared in his last edition of the *Systema Naturæ* (the 12th, 1767), and as we have given it above. In the earlier editions the term *Mollusca* does not seem to have occurred to him. The naked mollusks are distributed among the order *Zoophytes*, of his class *Vermes*, and the testaceous mollusks formed his third order of that class, *Testacea*. Among the first we find *Tethys*, under which he arranged the *Holothuriæ*; and *Limax* and *Sepia*, which he placed near the *Hydræ*. The second were not yet divided into *Univalves* and *Bivalves*. The genera *Patella* and *Cochlea* seem to have embraced all the turbinated univalves; and *Cypræa*, *Haliotis*, and *Nautilus*, the simple univalves. All the *Bivalves* appear to be collected under the term *Concha*; and the *Ascidiæ*, under the name of *Microcosmus*, seem to have found a place under his *Testacea*.

It is in the tenth edition (1758) that we first trace considerable augmentations, which increased in the last that received the correction of the great Swedish naturalist's own hand, and which appeared in three volumes: the first part of the first volume being published in 1766; the second part of that volume, containing the *Insecta* and *Vermes*, in 1767; the second volume, containing the plants (*Regnum Vegetabile*), in 1767; and the third, containing the minerals (*Regnum Lapideum*), in 1768. Adanson's work was published at Paris in 1757, ten years before the second part of the second volume of the last edition of the *Systema Naturæ*. But Linnæus appears to have only profited by the labours of Guettard and Adanson to add to the genera of the orders *Mollusca* and *Testacea* of his *Vermes*, and to define them more closely. Geoffroy's publication appeared nearly at the same time with his own last edition. The object of Linnæus seems to have been to establish a nomenclature and form a system of conchology resting on the modifications of structure in the shell alone: in fact an arbitrary system which has now generally given way to systems founded upon more natural principles.

Pallas (*Miscellanea Zoologica*, 1766) seems to have been the first to point out the unsteady foundation on which the system of Linnæus rested. He shows that the subdivision of the testaceous mollusks, as adopted by Linnæus and his followers, resting on the shell only, without taking the animal into consideration, is far from natural; and, in that spirit of prophecy which is now fulfilled, he remarks that it cannot be preserved.

Bruguière, nevertheless, weighing the great influence which the system of Linnæus had exercised on zoology in general, and the powerful aid which it afforded to the student of that science, clung, in his *Dictionnaire des Vers*, to the method of the Swede in so many points that he may be said almost to have done little more than imitate him.

Bruguière admits the division of the two orders Molluscous Worms and Testaceous Worms. The first of these he subdivides into two sections, according to the presence or absence of *tentacula*, and consequently jumbles together a very heterogeneous mass of animals; for the same reason his second section is even more heterogeneous than the first. He however separates into a distinct order the *Echini* and *Star-fishes*.

In the second order, or that of *Testaceous Worms*, though the Linnæan principle is kept in view, the genera are more multiplied and their characters better defined; and as Bruguière is one of those authors who has greatly contributed to the advancement of this branch of zoology, we shall give an outline of his system of conchology.

He, like Linnæus, divides the *Testaceous Worms* into three sections, according to the number of the valves.

In the first (*Multivalves*) he places the *Chitons*, *Balanus*, and *Anatifa* (*Lepas* of Linnæus), *Teredo*, *Fistulana*, *Pholas*, *Chur* (a new and imaginary genus), *Anomia*, and *Crania*. We here have for the first time a separation of the Pedunculated and Sessile types of the Cirripeds (*Campylosomata* and *Acamptosomata*) pointed out under the generic appellations of *Anatifa* and *Balanus*, and the new genera *Fistulana* and *Crania*.

The *Bivalves* (second section) are divided into the regular and irregular.

Among the *Regular Bivalves* are three new genera, viz. *Acardo*, *Placuna*, and *Perna*.

The *Irregular Bivalves* contain the new genera *Trigonia*, *Pecten* (previously separated from the oysters by Müller and Poli), *Tridacna*, *Cardita* (formed at the expense of *Chama*, Linn.), and *Terebratula*, containing a division of *Anomia*.

The *Univalves* are subdivided into the *Unilocular*, or those without any partitions, and the *Multilocular*, or those which are furnished with regular partitions or *septa*.

The *Unilocular Univalves without a regular spire* contain *Patella* and *Fissurella*, divided for the first time, and, notwithstanding the observations of Pallas, *Dentalium*, *Serpula*, *Siliquaria*, and *Aspergillum*, among others; *Fissurella*, *Siliquaria*, and *Aspergillum* being new.

The *Unilocular Univalves with a regular spire* present a less heterogeneous assemblage. We find among them *Voluta* reduced to a more uniform genus by withdrawing from it some of the widely different species which Linnæus had congregated under that name, and the following new genera: *Ovula* (or rather *Ovulum*), *Oliva*, *Purpura*, *Cassis*, *Terebra*, *Fusus*, *Cerithium*, *Bulimus*, *Planorbis*, and *Natica*.

The *Multilocular Univalves* not noticed by Linnæus, but pointed out by Breyn or Breynius of Danzig, in his *Dissertatio de Polythalamiis, nova Testaceorum Classe* (1732), comprise the genera *Camerina*, *Ammonites*, and *Orthoceras*, at the expense of the genus *Nautilus* of Linnæus.

Gmelin, whose edition of Linnæus appeared about the same time with the work of Bruguière, requires but little notice. Four or five new genera were added to the *Systema Naturæ*, which received in this edition a great number of species, too many of them added carelessly and in a manner to create confusion, instead of dissipating it.

In 1791 Poli published the first volume of his splendid work, *Testacea utriusque Siciliæ eorumque Historia et Anatome*. Of the care with which the details are wrought out, and the magnificence and accuracy with which they are illustrated, it is impossible to speak too highly. But while Poli avoids the errors of those who sought to establish a system of testaceous mollusks on the structure of the shell alone, he runs into the opposite extreme, and rests his arrangement on the soft parts of the animal only, without any reference to the hard part or shell. He divides the *Mollusca* into three orders:—1. *Mollusca brachiata* (*Sepiæ* &c. of Linnæus, and the *Tritons* and *Serpulæ* of the same author). 2. *Mollusca reptantia* (Gastropods of the more modern authors). 3. *Mollusca subsilientia* (Multivalves and Bivalves of the old school, and characterised as being provided with a long foot, as being fixed to rocks or free, and as always wanting a head and eyes).

Of these families the most natural are the Bivalves, and their arrangement is based upon the structure of important parts.

Little seems to have been done for the science from 1789 to 1798, a period which included the French revolution and its reign of terror; but in 1798 a new era commenced, and George Cuvier published his *Tableau Elémentaire de l'Histoire Naturelle des Animaux*. This great man, clearly perceiving that Guettard, Adanson, Geoffroy, Müller, and Poli took a right view of the principles of classification when they proposed the organization of the animal as its basis, adopted that method, and united, as Pallas had done, under the name of *Mollusca* both the *Vermes* (*Mollusca*) and *Vermes* (*Testacea*) of Linnæus. Considering the absence or presence of a shell as a contingency of secondary importance, he divided the Mollusca into three sections,—the *Cephalopodous Mollusca*, the *Gastropodous Mollusca*, and the *Acephalous Mollusca*. Finally he arranged this 'Second Grand Division of the Animal Kingdom' in six classes, and gave the following method in his last edition of the *Règne Animal* (1830).

MOLLUSCA.

Class I.

CEPHALOPODA.

1. *Sepia* of Linnæus, containing the following genera and subgenera: Octopus, Polypus, Eledone, Argonauta, Bellerophon, Loligo, Loligopsis, Onychoteuthis, Sepiola, Sepioteuthis, and the Cuttles properly so called, viz. Sepia of Lamarck.—2. *Nautilus* of Linnæus, containing Spirula, the Nautili properly so called (Nautilus pompilius, &c.), Lituus, Hortolus, and Orthoceras.—3. *Belemnites*, including Actinocomax?*.—4. *Ammonites*, including the Ammonites properly so called (Simplegades of De Montfort), Planites of De Haan, Ceratites, Orbulites, Globites, Goniatites, Pelagus, Scaphites, Baculites (Tiranites, Rhabdites, Icthyosarcolites), Hamites, Turrilites (the last with M. Audouin's doubt).—5. *Camerina* (Nummulites of Lamarck), with their infinity of genera. [FORAMINIFERA.]

Class II.

PTEROPODA.

1, *Clio*. 2, *Cymbulia*. 3, *Pneumodermon*. 4, *Limacina*. 5, *Hyalæa*. 6, *Cleodora*, including Creseis, Cuvieria, Psyche, and Eurybia, of M. Rang, and perhaps *Triptera* of Quoy and Gaimard. 7, *Pyrgo* (fossil).

Class III.

GASTEROPODA.

Order 1.

Pulmonifera.

§ 1.

Pulmonifera Terrestria.

1, *Limax*, including Limax properly so called. *Arion*. Vaginulus. Testacella and Parmacella. 2, *Helix*, including Helix properly so called. Vitrina (Helicolimax of Férussac). Bulimus. Pupa. Chondrus and Succinea. 3, *Clausilia*. 4, *Achatina* (including Polyphemus of De Montfort).

§ 2.

Pulmonifera Aquatica.

1, *Onchidium*. 2, *Planorbis*. 3, *Limnæus* or *Limnæa*. 4, *Physa*, near which Cuvier would place *Scarabus* of De Montfort. 5, *Auricula*, including Carychium of De Férussac. 7, *Melampus* (*Conovulus*, Lam.)

Order 2.

Nudibranchiata.

1, *Doris*. 2, *Onchidoris*. 3, *Plocamoceros*. 4, *Polycera*. 5, *Tritonia*. 6, *Thethys* or *Tethys*. 7, *Scyllæa*. 8, *Glaucus*. 9, *Laniogerus*. 10, *Eolidia*. 11, *Cavolina*. 12, *Flabellina*. 13, *Tergipes*. 14, *Busiris*. 15, *Placobranchus*.

Order 3.

Inferobranchiata.

1, *Phyllidia*. 2, *Diphyllidia*.

Order 4.

Tectibranchiata.

1, *Pleurobranchus*. 2, *Pleurobranchæa* (*Pleurobranchidium* of De Blainville). 3, *Aplysia*. 4, *Dolabella*. 5, *Notarchus*. 6, *Bursatella*. 7, *Akera*, including Bullæa, Bulla, and the Akeræ properly so called (Doridium of Meckel, and Lobaria of De Blainville). 8, *Gastropteron*. 9, *Umbrella*.

Order 5.

Heteropoda. (Lam.)

These were all comprised by Forskal under his genus Plerotrachea, and comprehend

1, *Carinaria*. 2, *Atlanta*. 3, *Firola*. 4, the *Timoriennes* of Quoy and Gaimard. 5, the *Monophores* of the same. *Phylliroe* of Péron is placed here, but with doubt.

Order 6.

Pectinibranchiata.

Family of Trochöids.

1, *Trochus* (including Tectus, Calcar, Rotella, Cantharidus, Infundibulum, Telescopium, Solarium, and Euomphalus). 2, *Turbo*, including, as genera and subgenera, Turbo properly so called (which comprises both Turbo and Meleagris of De Montfort), Delphinula, Pleurotomaria, Turritella, Scalaria; together with certain terrestrial and freshwater subgenera, viz.: Cyclostoma, Valvata, and Paludina; and the following: Littorina, Monodon, Phasianella, Ampullaria (including Lanistes of De Montfort), Helicina, Melania, Rissoa, Melanopsis, Pirena, Acteon (Tornatella, Lam.), Pyramidella, Janthina, Nerita, Natica, Peloronta, Velates, Neritina, and Clithon.

Family of Capulöids.

1, *Capulus* (Pileopsis of Lamarck). 2, *Hipponyx*. 3, *Crepidula*. 4, *Pileolus*. 5, *Navicella* (Cimber of De Montfort). 6, *Calyptræa*. 7, *Siphonaria*. 8, *Sigaretus*. 9, *Coriocella*. 10, *Cryptosoma*.

---

* In the text Actinocomax is included in the section appropriated to the genus Belemnites, though it is spoken of as a genus. In the 'Table Méthodique' Actinocomax is printed as a genus, not a subgenus.

Family of Buccinoids.

1, *Conus.* 2, *Cypræa.* 3, *Ovula*, or rather *Ovulum*, including Volva (Radius?) and Calpurnus of De Montfort. 4, *Terebellum.* 5, *Voluta*, including Oliva, Volvaria, the true Volutæ (subdivided by Broderip[*] into Cymba—Cymbium of De Montf.—Melo, and Voluta), Marginella, Columbella, Mitra, and Cancellaria. 6, *Buccinum*, including Buccinum of Bruguière, Nassa, Eburna, Ancillaria, Dolium (the Tuns, and Partridge Tuns), Harpa, Purpura, Unicornus (Monoceros, Lam.), Ricinula (Sistrum of De Montf.), Concholepas, Cassis, Cassidaria (Morio of De Montf.), and Terebra. 7, *Cerithium* (including Potamides). 8, *Murex*, including Murex, Brug., which comprises the Murices properly so called (Murex, De Montf.), and Brontes, Typhis, Chicoreus, Aquillus, Lotorium, Triton, and Trophon of the same; Ranella (including Apollon of De Montf.); Fusus (including Fusus and Latirus of De Montf.); Struthiolaria; Pleurotoma; Clavatula; Pyrula (including Fulgur of De Montf.), and Fasciolaria. 9, *Strombus* (including Strombus, Lam., Pteroceras, Rostellaria, and Hippochrenes).

Order 7.

Tubulibranchiata.

1, *Vermetus*, including Vermilia. 2, *Magilus.* 3, *Siliquaria.*

Order 8.

Scutibranchiata.

1, *Haliotis*, including Padollus as a subgenus, and Stomatia. 2, *Fissurella.* 3, *Emarginula* (Palmarium of De Montfort). 4, *Parmophorus* (Scutus of De Montfort).

Order 8.

Cyclobranchiata.

1, *Patella.* 2, *Chiton.*

Class IV.

ACEPHALA.

Order 1.

Acephala Testacea (with four branchial *feuillets*, or leaflets).

Family of Ostraceans.

1, *Acardo*,[†] Brug., or *Ostracites*, La Peyrouse, including Radiolites, Sphærulites, Calceola, Hippurites, and Batolites. 2, *Ostrea*, Linn., including Ostrea, Brug., Gryphæa, Pecten, Lima, and Pedum. 3, *Hinnites.* 4, *Plagiostoma.* 5, *Pachytes.* 6, *Dianchora.* 7, *Podopsis.* 8, *Anomia.* 9, *Placuna.* 10, *Spondylus*, from which Lamarck has separated Plicatula. 11, *Malleus.* 12, *Vulsella.* 13, *Perna*, from which have been separated Crenatula, Gervillia, Inoceramus, Catillus, and Pulvinites. 14, *Etheria.* 15, *Avicula*, including Margarita. 16, *Pinna.* 17, *Arca*, Linn., including Arca, Lam., Cucullæa, Pectunculus, and Nucula. 18, *Trigonia.*

Family of Mytilaceans.

1, *Mytilus*, Linn., including Modiola and Lithodomus 2, *Anodon*, including Iridina, Dipsas, &c. 3, *Unio*, including Hyria and Castalia. 4, *Cardita.* 5, *Cypricardia*, and the *Coralliophaga* of M. de Blainville, *Venericardia*, and *Crassatella* (Paphia, Roiss.).

Family of Chamaceans.

1, *Chama*, Linn., including Tridacna, Hippopus, Chama (Brug.), Diceras, and Isocardia.

Family of Cardiaceans.

1, *Cardium*, including Hemicardium. 2, *Donax.* 3, *Cyclas*, including Cyrena, Cyprina, and Galathæa. 4, *Corbis*, Cuv., *Fimbria*, Megerle. 5, *Tellina.* 6, *Loripes.* 7, *Lucina.* 8, *Ungulina.* 9, *Venus*, including Astarte (Crassina, Lam.), Cytheræa, Capsa, and Petricola. 10, *Corbula.* 11, *Mactra.*

Family of the Enfermés.

1, *Mya*, including Lutraria, Anatina, Solemya, Glycymeris, Panopea, and Pandora. 2, *Byssomya.* 3, *Hiatella.* 4, *Solen*, including Sanguinolaria, Psammobia, and Psammothea. 5, *Pholas.* 6, *Teredo.* 7, *Fistulana.* 8, *Gastrochæna.* 9, *Teredina.* 10, *Clavagella.* 11, *Aspergillum.*

Order 2.

Acephala without shells.

1st Family (Simple).

1, *Biphora*, including Thalia, Salpa, and Dagysa. 2, *Ascidia*, including Cynthia, Phallusia, Clavellina, and Boltenia.

2. Family (Aggregate).

1, *Botryllus.* 2, *Pyrosoma.* 3, *Polyclinum.*

Class V.

BRACHIOPODA.

1, *Lingula.* 2, *Terebratula*, including Spirifer and Thecidea. 3, *Orbicula*, including Discina and Crania.

Class VI.

CIRRHOPODA.

(Lepas and Triton, Linn.)

1, *Anatifa*, including Pentalasmis, Pollicipes, Cineras, Otion, and Tetralasmis. 2, *Balanus*, including Acasta, Conia, Asema, Pyrgoma, Ochthosia, Creusia, Coronula, Tubicinella, and Diadema.

Such is the method finally proposed by Cuvier; and, while perusing it, the reader should remember that he had the advantage of reference to almost every author of note who had written on the subject, down to the year 1830. Not that this at all detracts from the excellent use which he has made of the materials at his command, and the grand philosophical views which he took of this intricate department of zoology.

We must now go back to 1798, when Lamarck began his publications on the Mollusca, by a paper in which he separated the great genus Sepia into three genera; and in 1799 he gave to the world his *Prodromus* of a new classification of shells, wherein he established several new genera. In this work he states his adhesion to the principles and views of Bruguière, whilst profiting by the observations of Cuvier as to the organization of the animals, but remarks that he has been compelled to restrict still more the characters of the genera, and consequently to augment their number. In 1801, when he published his *Animaux sans vertèbres*, he seems to have been convinced of the justice of the views of Cuvier; and no longer confining his attention to the shells, he followed very nearly the example of that great zoologist, and rested his system upon the organization of the soft parts, as well as on the form of the shell of the animal. The 1st vol. of the last edition, which received the corrections of Lamarck's own hand, was published in 1815, and the last vol. in 1822:[*] the following is the arrangement left by him.

Before we enter upon that part of the system which in strictness belongs to the subject before us, it will be necessary to give a succinct view of Lamarck's *Annelids.* These he divides into three orders:—

I. The Apod Annelids, containing the *Hirudinidæ* or Leeches, and the *Lumbricidæ* or Worms (Echiurées).

II. The Antennated Annelids, containing the *Aphroditidæ*, the *Nereididæ*, the *Eunicididæ*, and the *Amphinomidæ*.

III. The Sedentary Annelids, containing the *Dorsalidæ*, which include Arenicola and Siliquaria; the *Maldanidæ*, which include Clymene and Dentalium; the *Amphitritidæ*, which comprise Pectinaria, Sabellaria, Terebella, and Amphitrite, and the *Serpulidæ* (Spirorbis, Serpula, Vermilia, Galeolaria, and Magilus).

The *Annelids* immediately precede Lamarck's Class X.

CIRRHIPEDES.

Order 1.

Sessile Cirrhipedes.

§ 1. With a quadrivalve operculum.

Genera:—Tubicinella. Coronula. Balanus. Acasta.

§ 2. With a bivalve operculum.

Pyrgoma. Creusia.

Order 2.

Pedunculated Cirrhipedes.

§ 1. Body completely enveloped by its tunic. Shell composed of contiguous pieces, leaving a free issue to the animal when they are opened.

Anatifa. Pollicipes.

§ 2. Body completely enveloped by its tunic, which nevertheless has an anterior opening. Shell formed of separate pieces, which have no need to open themselves for the issue of the arms of the animal.

Cineras. Otion.

---

[*] In the 'Règne Animal,' 'Sowerb.' is erroneously printed for 'Brod.'

[†] The species figured by Brug., 'Encyclop.,' pl 173. ff. 1, 2, 3, appears to be but a double epiphysis of the vertebræ of a Cetacean.

[*] There is another edition of Lamarck's 'Animaux sans vertèbres,' now (1839) in a course of publication, with valuable notes and additions by MM. Deshayes and Milne Edwards.

Class XI.

CONCHIFERA.

Order 1.

Conchifera Dimyaria.

Two muscles of attachment at least. Shell, internally, with two muscular impressions, which are separate and lateral.

(1) Shell regular, generally equivalve.

(A) Shell gaping, in general, at the lateral extremities, its valves being approximated.

(*) *Crassipede Conchifers.*—Mantle with its lobes united anteriorly, either entirely or partially; foot thick posterior: gape of the shell always remarkable, often considerable.

(1) Shell either contained in a tubular sheath, distinct from its valves, or entirely or partially incrusted in the wall of the sheath, or projecting externally.

Family Tubicolidæ[†].

Aspergillum. Clavagella. Fistulana. Septaria. Teredina. Teredo.

(2) Shell without a tubular sheath.

(*a*) Ligament external.

(†) Shell either furnished with accessory pieces, foreign from its valves, or gaping very much anteriorly.

Family Pholadidæ.

Pholas. Gastrochæna.

(††) Shell without accessory pieces, and gaping at the lateral extremities only.

Family Solenidæ.

Solen. Panopæa. Glycymeris.

(*b*) Ligament internal.

Family Myidæ.

Mya. Anatina.

(**) *Tenuipede Conchifers.*—Mantle with its lobes not united, or hardly united anteriorly; foot small, compressed; gaping of the shell often considerable.

(†) Ligament internal.

Family Mactridæ.

(1) Ligament internal only.

(*a*) Shell gaping on its sides.

Lutraria. Mactra.

(*b*) Shell not gaping at its sides.

Crassatella. Erycina.

(2) Ligament visible externally, or double, one part being internal, the other external.

Ungulina. Solemya. Amphidesma.

Family Corbulidæ.

(Shell inequivalve. Ligament internal.)

Corbula. Pandora.

(††) Ligament external only.

Family Lithophagidæ.

Boring shells without accessory pieces, without any particular sheath, and more or less gaping at their anterior side. Ligament of the valves internal.

Saxicava. Petricola. Venerupis.

Family Nymphidæ.

Two cardinal teeth at most in the same valve. Shell often gaping a little at the lateral extremities. Ligament external; Nymphs, in general, gaping outwards.

(1) Solen-like Nymphidæ.

Sanguinolaria. Psammobia. Psammotæa.

(2) Tellen-like Nymphidæ.

(*a*) Lateral teeth, one or two.

Tellina. Tellinides. Corbis. Lucina. Donax.

(*b*) No lateral teeth.

Capsa. Crassina.

(B) Shell closed at the lateral extremities, when the valves are closed.

(***) *Lamellipede Conchifers.* Foot flattened, lamelliform, not posterior.

Family Conchidæ.

Three cardinal teeth at least in one valve, with as many or less in the other. Lateral teeth sometimes.

1. Fluviatile Conchidæ.

Shell with lateral teeth, and covered with a false epidermis.

Cyclas. Cyrena. Galathea.

2. Marine Conchidæ.

No lateral teeth in the greater number; rarely an epidermis, which covers the whole shell except the umbones.

Cyprina. Cytherea. Venus. Venericardia.

Family Cardiidæ.

Cardinal teeth irregular, either in their form or situation, and accompanied, in general, by one or two lateral teeth.

Cardium. Cardita. Cypricardia. Hiatella and Isocardia.

Family Arcidæ.

Cardinal teeth small, numerous, intrant, and disposed in each valve on a line which is either straight, or arched, or broken.

Cucullæa. Arca. Pectunculus. Nucula. Trigonia and Castalia.

Naiidæ.

Fluviatile shells, whose hinge is sometimes furnished with an irregular cardinal tooth which is simple or divided, and with a longitudinal tooth which is prolonged under the corselet; and sometimes is without any tooth at all, or is furnished along its length with irregular, granulous tubercles.

Muscular impression posterior and compound. Umbones with the epidermis peeled off, and frequently eroded.

Unio. Hyria. Anadonta (or rather Anodon) and Iridina.

(****) *Ambiguous Conchifers.*

Family Chamidæ.

Shell irregular, inequivalve. A single cardinal tooth which is oblique and subcrenate, inserted into a little pit in the opposite valve.

Muscular impressions two, distant, lateral. External ligament depressed.

Diceras. Chama. Etheria.

Order 2.

Conchifera Monomyaria.

Only one muscle of attachment, which seems to traverse their body.

Shell with an internal subcentral muscular impression.

(*) Ligament marginal, elongated on the border, sublinear.

(*a*) Shell transverse, equivalve, with an elongated muscular impression, bordering the upper limb.

Family Tridacnidæ.

Tridacna. Hippopus.

(*b*) Shell longitudinal or subtransverse, with a muscular impression contracted into an isolated space without bordering the limb.

(†) Ligament at the lateral border of the shell, and always entire.

Family Mytilidæ.

Hinge with a subinternal ligament, which is marginal, linear, very entire, occupying a great part of the anterior border. Shell rarely foliated.

Modiola. Mytilus. Pinna.

(††) Ligament at the lower border of the shell, or divided.

Family Mallëidæ.

Ligament marginal, sublinear, either interrupted by crenulations or serial teeth, or altogether simple. Shell subinequivalve, foliated

Crenatula. Perna. Malleus. Avicula. Meleagrina.

(**) Ligament not marginal, contracted into a short space under the umbones, and not forming a tendinous tube under the shell

(*a*) Ligament internal or demi-internal. Shell regular, compact, not foliated.[*]

Family Pectinidæ.

Pedum. Lima. Plagiostoma. Pecten. Plicatula. Spondylus. Podopsis.

(*b*) Ligament internal or demi-internal. Shell irregular, foliated, sometimes papyraceous.

Family Ostreidæ.

(1) Ligament demi-internal, shell foliated, but nevertheless often acquiring great thickness.

[†] Lamarck does not use the termination 'idæ;' but it is now so generally employed in zoology to designate family names, that we have thought it advisable to adopt the form for the Lamarckian families.

[*] The term foliated is here applied as relating to the structure of the shell itself, rather than to the external excrescences.

Gryphæa. Ostrea. Vulsella.

(2) Ligament internal. Shell delicate, papyraceous.

Placuna. Anomia.

(***) Ligament either null or unknown, or represented by a tendinous chord which sustains the shell.

(*a*) Ligament and animal unknown. Shell very inequivalve.

Family Rudistidæ.

Sphærulites. Radiolites. Calceola. Birostrites. Discina. Crania.

(*b*) Shell adherent, either immediately or by a tendinous chord which sustains it, and serves as a ligament. Animal with two opposed arms, which are opposed, ciliated, and cirrhous.

Family Brachiopodidæ.

Conchifers having near the mouth two opposed, elongated, ciliated arms, rolled spirally when in repose. Mantle bilobated, the lobes separated anteriorly, enveloping or covering the body.

Shell bivalve, adhering to marine bodies, either immediately or by a tendinous chord.

Orbicula. Terebratula. Lingula.

Class XII.

MOLLUSCA.

Order 1.

Pteropoda.

No foot for creeping, nor arms for progress or seizing the prey. Two fins opposed and similar, proper for natation. Body free and floating.

Hyalæa. Clio. Cleodora. Limacina. Cymbulia. Pneumodermon.

Order 2.

Gasteropoda.

Animals with a straight body, never spiral nor enveloped in a shell which can contain the entire animal; having under the belly a foot or muscular disc united to the body nearly throughout its length, and serving for creeping.

Some naked, others protected by a dorsal shell, not imbedded; and others, on the other hand, containing a shell more or less hidden in their mantle.

1st Section.

Hydrobranchiata.

Branchiæ, whatever be their position, elevated either in a net-work, in laminæ, in a pectinated form, or in a ribbon-like shape. The animals of this section breathe water only.

(*a*) Branchiæ external, placed above the mantle, either on the back or on the sides, and being in no particular cavity.

Family Tritonidæ.

Glaucus. Eolis. Tritonia. Scyllæa. Tethys. Doris.

(*b*) Branchiæ placed under the border of the mantle, and disposed in a longitudinal series round the body, or on one side only; not being in any particular cavity.

Family Phyllididæ.

Phyllidia. Chitonellus. Chiton. Patella.

Family Semiphyllididæ.

Branchiæ placed under the border of the mantle, and disposed in a longitudinal series on the right side of the body only.

Pleurobranchus. Umbrella.

(*c*) Branchiæ placed in a particular cavity upon the back, situated anteriorly near the neck. Shell always external, and covering the soft parts.

Family Calyptræidæ.

Parmophorus. Emarginula. Fissurella. Pileopsis. Calyptræa. Crepidula. Ancylus?

(*d*) Branchiæ placed in a particular cavity towards the posterior part of the back, and covered either by the mantle or by an opercular escutcheon.

(†) No tentacula.

Family Bullidæ.

Akera. Bullæa. Bulla.

(††) With tentacula.

Family Laplysidæ.

Laplysia. Dolabella.

2nd Section.

Pneumobranchiata.

Branchiæ creeping, in the form of a vascular net-work, on the wall of a particular cavity, the aperture of which is a hole which the animal contracts or dilates at its pleasure. Animals of this section breathe nothing but air.

Family Limacidæ.

Onchidium. Parmacella. Limax. Testacella. Vitrina.

Order 3.

Trachelipoda.

Body spiral in its posterior part, this part being separated from the foot, and always enveloped in the shell. The foot free, flattened, attached to the lower base of the neck, or to the anterior part of the body, and serving for creeping. Shell spirivalve and sheathing (engainante).

Section I. (Phytiphagous.)

Trachelipods without a projecting siphon, and respiring in general by means of a hole. The greater part *phytiphagous* and furnished with jaws. Shell with the aperture entire, having at its base neither dorsal subascending notch nor canal.

* Trachelipods respiring air only. Shell spirivalve, unarmed (mutique), not distinctly nacreous.

Family Colimacidæ (terrestrial).

(*a*) Four tentacles.

Helix. Carocolla. Anostoma. Helicina. Pupa. Clausilia. Bulimus. Achatina. Succinea.

(*b*) Two tentacles.

Auricula. Cyclostoma.

Family Limnæidæ.

Amphibious. Living in the water, but coming to the surface to breathe. Shell with a sharp edge to the lip.

Planorbis. Physa. Lymnæa, or rather Limnæa.

(**) Trachelipods breathing water only. Branchiæ projecting in form of filaments, laminæ or tufts in the branchial cavity. Shell often nacreous, and often also having protuberant parts on the surface.

(*a*) Shell fluviatile, operculated, the left border of which does not resemble a demi-partition.

(†) Shell with disunited borders.

Family Melanidæ.

Melania. Melanopsis. Pirena.

(††) Shell with united borders.

Family Peristomidæ.

Valvata. Paludina. Ampullaria.

(*b*) Shell fluviatile or marine, whose left border or lip resembles a demi-partition.

Family Neritidæ.

Navicella. Neritina (fluviatile). Nerita. Natica (marine).

(*c*) Shell marine, whose left lip does not resemble a demi-partition.

(†) Shell floating at the surface of the water.

Family Janthinidæ.

Janthina.

(††) Shell not floating, having the aperture very wide; no columella.

Family Macrostomidæ.

Sigaretus. Stomatella. Stomatia. Haliotis.

(†††) Aperture without any particular width; plaits on the columella.

Family Plicacidæ.

Tornatella. Pyramidella.

(††††) No plaits on the columella.

(*a*) Borders of the aperture united circularly.

Family Scalaridæ.

Vermetus. Scalaria. Delphinula.

(*b*) Borders of the aperture disunited.

Family Turbinidæ.

Solarium. Rotella. Trochus. Monodonta, or rather Monodon. Turbo. Planaxis. Phasianella. Turritella.

Section II. (Zoophagous.)

Trachelipods with a projecting siphon, and which only breathe the water which arrives at the branchiæ by means of this siphon. These feed on animal substances only, are marine, have no jaws, and are furnished with a retractile proboscis.

Shell spirivalve, sheathing the soft parts, with an aperture which is either canaliculated, or notched, or turned up at its base.

(*a*) Shell with a canal more or less long at the base of its aperture, and the right border of whose lip does not change with age.

Family Canaliferidæ.

§ 1.

No constant bourrelet on the right lip of the species.

Cerithium. Pleurotoma. Turbinella. Cancellaria. Fasciolaria. Fusus. Pyrula.

§ 2.

A constant bourrelet on the right lip in all the species.

(a) No bourrelet on the spire.

Struthiolaria.

(b) *Bourrelets* on the spire.

Ranella. Murex. Triton.

(c) Shell with a canal more or less long at the base of its aperture, and the right border of whose lip changes its form with age, and has a sinus inferiorly.

Pteridæ (Ailées or Wing-shells).

Rostellaria. *Pterocera*, or rather Pteroceras. Strombus.

(c) Shell with a short canal, ascending posteriorly, or with an oblique notch at the base of its aperture, this demi-canal being directed towards the back.

Family Purpuridæ (*Purpurifères*).

§ 1.

An ascending canal, or recurved towards the back.

Cassidaria. Cassis.

§ 2.

An oblique notch, directed backwards.

Ricinula. Purpura. Monoceros. Concholepas. Harpa. Dolium. Buccinum. Eburna. Terebra.

(d) No canal at the base of the aperture, but a subdorsal notch and plaits on the columella.

Family Columellidæ (Columellaires).

Columbella. Mitra. Voluta. Marginella. Volvaria.

(e) Shell without a canal, but having the base of its aperture notched or versant, and the whorls of the spire large, compressed, and enrolled in such a manner that the last whorl nearly entirely covers the others.

Family Convolutidæ (Enroulées).

Ovula, or rather Ovulum. Cypræa. Terebellum. Ancillaria. Oliva. Conus.

Order IV.

Cephalopoda.

Mantle in form of a sac, containing the lower part of the body. Head projecting from the sac, surrounded by arms, which are not articulated, but furnished with suckers (ventouses), and which environ the mouth. Two sessile eyes; two horny mandibles in the mouth; three hearts; sexes separate.

1st Division.

Polythalamous Cephalopods.

Shell multilocular, enveloped completely or partially, and which is enclosed in the posterior part of the animal, often with adherence.

* Shell multilocular, with simple chambers.

(1). Shell straight or nearly straight; no spiral.

Family Orthoceratidæ.

Belemnites. Orthoceras. Nodosaria. Hippurites. Conilites.

(2). Shell partially spiral; last whorl continued in a straight line.

Family Lituolidæ.

Spirula. Spirolina. Lituola.

(3). Shell semi-discoid; spire eccentric.

Family Cristacidæ.

Renulina. Cristellaria. Orbiculina.

(4). Shell globulous, spheroidal, or oval, with enveloping whorls, or partitions united *en tunique*.

Family Sphærulidæ.

Miliola. Gyrogona.* Melonia.

(5). Shell discoid, with a central spire, and partitions extending from the centre to the circumference.

Family Radiolidæ.

Rotalia. Lenticulina. Placentula.

(6). Shell discoid, with a central spire, and partitions which do not extend from the centre to the circumference.

Family Nautilidæ.

Discorbis. Siderolites. Polystomella. Vorticialis. Nummulites. Nautilus.

** Shell multilocular, with chambers parted sinuously at the edges.

Family Ammonitidæ.

Ammonites. Orbulites. Ammonoceras. Turrilites. Baculites.

2nd Division.

Monothalamous Cephalopods.

Shell unilocular, entirely external, and enveloping the animal.

Genus Argonauta.

3rd Division.

Sepiary Cephalopods.

No shell, either internal or external. A solid cartilaginous or horny body, contained in the interior of the greater part of the animals.

Genera.—Octopus. Loligopsis. Loligo. Sepia.

Order V.

Heteropoda.

Body free, elongated, swimming horizontally. Head distinct; two eyes. No arms surrounding the head; no foot under the belly or under the throat for creeping. One or more fins, without any regular order, and not disposed by pairs.

Genera.—Carinaria. Pterotrachea. Phylliroë.

Such was Lamarck's arrangement, as he finally left it, after various modifications in the course of his publications, from the commencement of them to the second edition of his 'Animaux sans vertèbres.' During that interval many authors had presented their views to the public, and we proceed to notice some of them.

In 1801, M. d'Audebard de Férussac (the father) produced a system of Conchology based on the consideration of the animal and its shell. He introduced some observations on the complete or incomplete state of what he calls the 'spiral cone' of the shell, and the point of attachment of the foot, under the neck or under the belly of the Gasteropods. His views were limited to the terrestrial and fluviatile Mollusks, or 'Mussulines,' as he calls them, and subdivides them into orders almost as numerous as his genera, among which we find *Helicolimaces*, forming the passage between the *Limaces* and the *Helices*.

The work of M. Bosc, in the supplements to Buffon (Det., 1802), may be considered as rather of a retrograde character, for it still clung to the system of Linnæus, as amended by Bruguière; and, notwithstanding the progress already made, we find him adhering to the terms *Molluscous Worms* and *Testaceous Worms*, as designating the *Naked* and *Testaceous Mollusca*. His divisions were nearly those of Bruguière, though he adopted the new subdivisions which Cuvier and Lamarck had established, and appears to have been conscious of the value of those innovations. Bosc was an observer, and had studied many of the *Mollusca* in a living state. He established many new facts and some new genera.

In 1801 appeared the *Prodromus* of the work of Draparnaud, which was not published till after his death in 1805, on the Terrestrial and Fluviatile Mollusca of France. This work is conceived and executed in a philosophical spirit, and with rational views of a natural system of classification. He abandoned the arbitrary method of Linnæus, and returned to the principle proposed by Réaumur (1711) in his 'Memoir on the Progressive Motions of Shells,' making his classification that of Cuvier.

The 'Natural History of Mollusca,' for Sonnini's edition of Buffon, was hardly commenced by Denys de Montfort, and almost entirely executed by M. de Roissy. The classification is carried out on the principles of Cuvier, but the author differs from Cuvier on some points, as, for instance, in thinking that the section of the Ascidians ought not immediately to follow that of the Oysters, and that the aperture which Cuvier regarded as anterior in Biphora was really posterior—an opinion in which he is supported by MM. Bosc, Péron, De Blainville, Chamisso, and Kuhl. In this work the analogy of the Polythalamous or chambered shells is pointed out. M. de Roissy appears to have perceived the passage from the Univalve to the Bivalve Mollusks by means of the *Patellæ*; and he seems to have been the first who placed *Aplysia* next to *Bullæa*, a position which it still holds.

M. Dumeril in 1806 published his '*Zoologie Analytique*;'

* Lamk.

* See Pl. [illegible]

tique' a classification of *Mollusca* nearly similar to that of Cuvier. M. Duméril divides the *Mollusca* into five orders: *Cephalopoda*, *Pteropoda*, *Gasteropoda*, *Acephala*, and *Brachiopoda*. The principal novelties in this publication were a division of the *Gasteropoda*, according to their organs of respiration, into three families—*Dermobranchiata*, *Siphonobranchiata*, and *Adelobranchiata*—which correspond nearly to the three divisions established on the structure of the shell; and a separation of the *Brachiopoda* as a distinct order.

In 1808 Denys de Montfort published his *Univalves Cloisonnées*, and in 1810 the second volume of his *Conchyliologie Systematique*, containing the *Univalves non Cloisonnées*. His genera are very numerous, and not many of them are retained at present by zoologists, though they are for the most part neatly defined. His method is only carried out with regard to the Univalves; but his primary division rests upon the number of valves, and is separated into *Univalves*. *Multivalves*, and *Bivalves*, as in the systems of the older conchologists. He differs however in restricting the term *Multivalves* to shells made up of several united pieces, without any solution of continuity; whilst he applies the term *Dissivalves* to shells made up of many pieces, but not coherent nor adherent to each other, as *Teredo*, *Fistulana*, *Balanus*, &c.

Oken, in 1810, read to the society of Gottingen a paper upon the knowledge of Mollusca apart from their shells and upon a natural classification established upon this basis; and carried out this principle in his 'Manual of Nat. Hist.,' published at Jena in 1816. Our limits will not allow us to do more than call the reader's attention to this work, which he will find well worthy of perusal, though it does not contain any new principle of arrangement, and there is somewhat too much of change of name about his genera, of which there are but few really new; nor can we do more than hint at the work of M. Rafinesque (Palermo, 1814). About the year 1816 much light was thrown on the *Aggregated Mollusca* by Lesueur, Desmarest, and above all by the great Savigny, and in 1817 M. de Blainville first made known the principles of his system, which he afterwards carried out to its completion, and to which we shall call attention in the proper place. The systems of Goldfuss and Ranzani appeared in the same year, 1820, the first at Nuremberg and the second at Bologna; the first may be regarded as a compilation of the labours of those malacologists who had embraced the natural system; and the basis of the second, as far as the Cirrhipeds are concerned, rests on the structure of the shell and its operculum without regard to the animal, and, as far as relates to the acephalous mollusks, does little more than give new denominations to the four sections of that division.

M. de Férussac (the son) divided (1819) the Mollusca into two grand sections, the *Cephalous* and the *Acephalous*.

Cephalous Mollusca.

These are divided into three classes—Cephalopods, Pteropods, and Gastropods.

The first class, *Cephalopods*, contained the two orders, Decapods and Octopods, as in the arrangement of Dr. Leach. This class in the system of De Férussac embraces all the naked cephalopods and all the animals with multilocular shells; but was subsequently considerably modified in a joint work with M. d'Orbigny.

The second class, *Pteropods*, which originally consisted of the families Hyalææ, Limacinæ, the Clios, the Pneumoderms, and the Phyllirhoes, also underwent considerable changes in a subsequent and joint work with M. Rang.

The third class, *Gastropods*, are divided into the following orders and suborders:—1. Nudibranchians (Anthrobranchians and Polybranchians). 2. Inferobranchians (Phillidians and Semi-phillidians). 3. Tectibranchians. 4. Pulmonians without an operculum (Geophilians, Gehydrophylians, and Hygrophilians). 5. Operculated Pulmonians. 6. Pectinibranchians (Pomastomes, Hemipomastomes, Apomastomes, and Adeloderms). 7. Scutibranchians Ormiers, (Haliotis, &c.), Calyptracians, Heteropods. 8. Cyclobranchians (Chismobranchians and Polyplaxiphores).

Acephalous Mollusca.

These are divided into four classes—Cirripedes, Brachiopods, Lamellibranchians, and Tuniciers.

The first, *Cirripedes*, is divided into the orders—Sessile edes and Pedunculated Cirripedes.

The second, *Brachiopods*, contains the three families Lingulidæ, Terebratulidæ, and Cranidæ.

The third, *Lamellibranchians*, comprehends five orders—the Ostraceans, Mytilaceans, Benetiers (Tridacna and Hippopus), the Cardiaceans, and the Enfermés (Myidæ, Solenidæ, Pholidæ, and Tubicolidæ).

The fourth, *Tuniciers*, consists of the two orders Tethid Ascidians (Tethidæ and the Pyrosomes) and Thalid Ascidians (Biphora, &c.).

In England Dr. Leach had been active in introducing a natural system, as appears from his published papers, descriptions, and works. He had it in contemplation to publish a general history of English Mollusca; but the most distressing of maladies deprived zoology of one of its most zealous cultivators, and the work has never appeared.

Mr. Gray (John Edward) published in the *London Medical Repository* (1821), his system, which divides the Mollusca (taken in the largest sense of the word) into seven classes.

The first, *Antliobrachiophora* (Cephalopods) consists of three orders—Anosteophora, Sepiæphora, and Nautilophora.

The second, *Gasteropodophora*, is divided into three subclasses—*Pneumobranchia*, *Cryptobranchia*, and *Gymnobranchia*.

The first of these *subclasses* contains two orders—Adelopneumona and Phaneropneumona. The second embraces nine orders—the Ctenobranchia, which are divided into six sections by the application of a new principle, viz. the form of the operculum: the Trachelobranchia; the Monopleurobranchia; the Notobranchia; the Chismatobranchia; the Dicranobranchia; the Cyclobranchia; the Polyplacophora; and the Dipleurobranchia. The third *class* consists of two orders—Pygobranchia and Polybranchia.

Mr. Gray's third class, *Gasteropterophora*, corresponds with the Heteropoda of Lamarck, and is similar to M. de Blainville's order Nucleobranchiata.

The fourth class, *Stomatopterophora*, corresponding with the Pteropoda, contains two orders, Pterobranchia and Dactyliobranchia.

The fifth class, *Saccophora* (Tuniciers of Lamarck), consists of three orders—Holobranchia, Tomobranchia, and Diphyllobranchia.

The sixth, *Conchophora*, consists of orders depending on the number of muscular impressions, and denominated from the form of the foot, as Cladopoda, Leptopoda, Phyllopoda, Pogonopoda, and Micropoda.

The seventh, *Spirobrachiophora*, corresponds with the Brachiopoda.

M. de Blainville, who in 1814 had published his first sketch of a methodical arrangement of the *Malacozoa*, as he designates the animals on which we are treating, and further developed that method in 1817 in his 'Prodromus' of a general classification of the animal kingdom. The organ upon which that arrangement is based is the organ of respiration, and it was finally perfected in the method which appeared in his 'Manuel de Malacogie,' (1825). We here give an outline of it.

Type.

MALACOZOA.

Class I. Cephalophora.

Order 1.

Cryptodibranchiata.

Family 1. Octocera, containing the genus Octopus, which includes Eledone (Leach) and Ocythöe (Rafinesque).

Family 2. Decacera, including the genus Loligo (Sepiola and Cranchia, Leach. Onychoteuthis, Lichtenst., the Sagittated Calamaries, Pteroteuthis, Sepioteuthis) and the genera Sepia. Beloptera.

Order 2.

Cellulacea.

Family 1. Spherulacea, consisting of the genus Miliola (including Pollontes of De Montfort), Melonia (including Borelis of De Montfort), Saracenaria, and Textularia.

Family 2. Planulacea, comprising Renulina, including Frondicularia of Defrance; and Peneroplis, including Planularia of Defrance.

Family 3. Nummulacea, containing Nummulites, including Lycophris of De Montf.; Helicites, including Rotalites and Egeon of De Mont.; Siderolites, including Tinoporus and Siderolithes of De Montf.; Orbiculina, including

Bron, Hælerus and Arthasia of the same; Pluminulina, including Pyrgula and Florina of the same; and Verticillites, including Cleomena, Sporilus, and Antenorites of the same.

Order 3.

Polythalamacea.

Family 1. Orthocerata. *Genera* * (with simple chambers or partitions), Belemnites, including Callirhoe, Hibolithes, Porodragus, Cetocis, Acamas, and Paclites of De Montf.; Conularia; Conilites, including Achelois, Amimonus and Thalamus of the same; Orthoceras, including Nodosaria (Lam.), Raiphyx, and Molossus of De Montf. ** (with sinuous chambers), Baculites, including Tiranites of the same.

Family 2. Lituacea. *Genera* * (with simple chambers), Ichthyosarcolithus; Lituola; Spirula, including Hortolus and Lituites of De Montf., and Spirolina of Lam. ** (with sinuous chambers), Hamites and Ammonoceratites.

Family 3. Cristacea. *Genera*, Crepidulina, including Astacolus, Cancris, and Periples of De Montf.; Orbis; and Linthuris.

Family 4. Ammonacea. *Genera*, Discorbites; Scaphites; Ammonites; and Simplegas, including Ammonites, Planulites, and Amaltheus of De Montf.

Family 5. Nautilacea. *Genera*, Orbulites, including Aganides and Pelagus of De Montf.; Nautilus, including Angulithes, Oceanus, and Bisiphytes of the same; Polystomella, including Geophonus, Pelorus, Elphidium, Themeon, Chrysolus, and Melonis of the same; Lenticulina, including Patrocles, Nonion, Macrodites, Robulus, Lampas, Pleuronia, Antenor, Clisiphontes, Rhinocurus, Herion, and Spincterules of the same.

Family 6. Turbinacea. *Genera*, Cibicides; Rotalites, including Storilus, Cidarollus, and Cortalus of De Montf.

Family 7. Turrilitacea. *Genus*, Turrilites.

Class II.

Paracephalophora.

Subclass I.

Paracephalophora Dioica (Aquatic, but capable of living for some time out of water).

§ 1.

Organs of respiration, and shell non-symmetrical, and almost constantly turned spirally from left to right.

Order 1.

Siphonobranchiata.

Family 1. Siphonostomata (Murex, Linn.). *Genera* * (no persistent bourrelet on the right lip), Pleurotoma, including Clavatula, Lam.; Rostellaria, including Hippochrenes of De Montf.; Fusus, including Latirus of De Montf.; Pyrula, including Fulgur of De Montf., and Melongena and Rapana of Schum.; Fasciolaria; Turbinella, including Polygonum of Schum.; Triton, including Lampusia, Aquillus, and Persona of De Montf., and Struthiolaria of Lam.; Ranella, including Bufonaria and Apollon of De Montf.; Murex, including Brontes, Chicoreus, Typhis, and [illegible] of the same.

Family 2. Entomostomata (Buccinum, Linn.). *Genera* * (Turriculated Entomostomes), Cerithium, including Vertagus of Schum.; Triphora or Tristoma of Deshayes; Nerinea of Defrance, Potamides of Brongniart, Pyrazus of De Montf., and Pirena of Lam.; Melanopsis; Planaxis; Subula. ** (Turbinaceous Entomostomes, or those whose spire is moderately elongated and rarely subturriculated), Terebra; Eburna; Buccinum, including Alectrion and Cyclops of De Montf. and Nassa of Lam. *** (Ampullaceous Entomostomes, or those whose shell is in general globulous), Harpa; Dolium, including Perdix of De Montf.; Cassidaria, including Oniscia of Sowerby; Cassis; Ricinula, including Sistrum of De Montf.; Cancellaria; Purpura, including Monoceros of De Montf. **** (Patelloid Entomostomes, or those whose shell is in its totality very wide, very flat, with a spire but little marked, and no columella), Concholepas.

Family 3. Angyostomata. *Genera* * (an operculum), Strombus, including Pterocera of Lam.; Conus, including Rhombus, Cylinder, Rollus, and Hermes of De Montf. ** (no operculum), Terebellum, including Seraphs of De Montf.; Oliva; Ancillaria; Mitra,† including Turris of De Montf.; Imbricaria of Schum., and Conohelix of Swainson; Voluta, including Turbinellus of Oken and Cymbium of De Montf.; Marginella, including Volvaria of Lam.; Persicula;* Cypræa; Ovula, including Calpurnus, Ultimus, and Radius of De Montf.

Order 2.

Asiphonobranchiata.

Family 1. Goniostomata (Trochus, Linn.). *Genera*, Solarium, including Maclurites of Lesueur and Euomphalus of Sowerby; Trochus, including Infundibulum, Phorus, Cidaris, Tectus, Telescopium and Cantharidus of De Montf., and Rotella of Lam.

Family 2. Cricostomata (Turbo, Linn.). *Genera*, Turbo, including Clanculus and Meleagris of De Montf.; Labio of Oken, Monodonta of Lam., and Littorina of De Férussac; Pleurotomaria; Delphinula, including Trigonostoma; Turritella; Proto; Scalaria, including Aciona of Leach; Vermetus; Siliquaria; Magilus; Valvata; Cyclostoma, including Cyclophorus of De Montf.; and Paludina.

Family 3. Ellipsostomata. *Genera*, Melania; Rissoa, including Alvania of Risso; Phasianella; Ampullaria, including Lanistes of De Montf.; Helicina, including Ampullina and Olygira of Say; Pleurocera, including Oxytrema of Rafinesque.

Family 4. Hemicyclostoma (Nerita, Linn.). *Genera*, Natica, including Polinices of De Montf.; Nerita, * (right lip dentated, Nerita, Lam.), Pelorenta of Oken and Clithon of De Montf. ** (right lip not toothed), Neritina, Lam.; Velates, De Montf.; Pileolus, Sow.; Septaria.

Family 5. Oxystoma. *Genus*, Janthina.

Subclass II.

Paracephalophora Monoica.

§ 1.

Organs of respiration, and shell, where it exists, nonsymmetrical.

Order 1.

Pulmobranchiata.

Family 1. Limnacea. *Genera*, Limnæa, including Radix of De Montf. and Omphiscola of Rafinesque; Physa; Planorbis.

Family 2. Auriculacea (Voluta, pars, Linn.). *Genera*, Pedipes, including Tornatella‡ and Conovulus, Lam.; Auricula, including Scarabus of De Montf., Carychium of Müll., and Phytia of Gray; Pyramidella.§

Family 3. Limacinea (Helix, Linn., terrestrial). * (anterior border of the mantle elevated into a roll (bourrelet) and not a buckler; a shell). *Genera*, Succinea, including Amphibulimus, Lam.; Bulimus, including Bulimulus, Leach; Achatina, including Liguus and Polyphemus of De Montf.; Clausilia; Pupa, including Chondrus of Cuvier, Gibbus of De Montf., Vertigo of Müll., and Partula of De Férus.; Tomogeres (Anostoma, Lam.); Helix * (circumference of the shell constantly carinated or subcarinated at all ages, Carocolla, Lam.), including Iberus, Caracolus, Acavus and Zonites of De Montf., and Helicella of Lam. ** (anterior border of the mantle enlarged into a kind of buckler; shell null or nearly membranous), Helicolimax, including Helixarion of De Férus.; Testacella; Parmacella; Limacella; Limax, including Arion of De Férus.; Philomycus and Eumeles of Rafin.; Onchidium, including Veronicella of De Blainv.

Order 2.

Chismobranchiata.

Coriocella; Sigaretus; Cryptostoma; Oxinoe; Stomatella;‖ and Velutina.

Order 3.

Monopleurobranchiata.

Family 1. Subaplysiacea. *Genera*, Berthella; Pleurobranchus;¶ and Pleurobranchidium.

Family 2. Aplysiacea. *Genera*, Aplysia, including Acteon of Oken; Dolabella; Bursatella; Notarchus; and Elysia.

---

† M. [illegible]

* Probably only the young of Cypræa, notwithstanding Adanson's observation, that he had seen both young and old ones. [illegible] The figures represent the young of a Cypræa.

‡ M. de Blainville, in his last corrections, says that the true Tornatella should be separated from Pedipes, [illegible] as Mr. Gray pointed out to him.

§ Hermaphrodite, according to Mr. Gray.

‖ Should be united, [illegible] with Cryptostoma. [illegible] De Blainville.

¶ M. de Blainville thinks that [illegible] of Gray and [illegible] belong to this genus.

Family 3. Patelloïdea. *Genera*, Umbrella (Acardo of Megerle); Siphonaria; and Tylodina.

Family 4. Akera. *Genera*, Bulla, including Aplustre of Schum. and Atys and Scaphander of De Montf.; Bellerophus; Bullæa; Lobaria; Sormetus; Gasteroptera; and Atlas.

§ 2.

Order 1.

Aporobranchiata.

Family 1. Thecosomata. *Genera*, Hyalæa; Cleodora, including Vaginella of Daudin and Styliola of Lesueur; Cymbulia, including Argivora of Lesueur; and Pyrgo.

Family 2. Gymnosomata. *Genera*, Clio, including Cliodites, Quoy, and Gaim.; and Pneumoderma.

Family 3. Psilosomata. *Genus*, Phylliröe

Order 2.

Polybranchiata.

Family 1. Tetracerata. *Genera*, Glaucus; Laniogerus; Tergipes; Cavolina; Eolida; Dermatobranchus; and Placobranchus.

Family 2. Dicerata. *Genera*, Scyllæa; Tritonia; and Tethys.

Order 3.

Cyclobranchiata.

Genera, Doris, including Polycera of Cuv.; Onchidoris; and Peronia.

Order 4.

Inferobranchiata.

Genera, Phyllidia and Linguella.

Order 5.

Nucleobranchiata.

Family 1. Nectopoda. *Genera*, Pterotrachea, including Firola, Firoloïdes and Sagitella of Lesueur; and Carinaria.

Family 2. Pteropoda. *Genera*, Atlanta, Spiratella, and Argonauta.

Subclass III.

Paracephalophora Hermaphrodita (Patella, Linn.).

§ 1.

Organs of respiration and shell symmetrical.

Order 1.

Cirrhobranchiata.

Genus, Dentalium, including Entale of Defr.

Order 2.

Cervicobranchiata.

Family 1. Retifera. *Genus* Patella, including Helcion of De Montf.

Family 2. Branchifera. *Genera* Fissurella; Emarginula, including Rimula of Defrance; and Parmophorus.

§ 2.

Organs of respiration and shell non-symmetrical.

Order 3.

Scutibranchiata.

Family 1. Otidea. *Genera*, Haliotis, including Padollus of De Montf., and Stomatia of Lam.; and Ancylus.

Family 2. Calyptracea. *Genera*, Crepidula; Calyptræa; Capulus; Hipponyx; and Notrema.

Class III.

Acephalophora.

Order 1.

Palliobranchiata.

§ 1.

Shell symmetrical.

Genera, Lingula, Terebratula, including Pentamerus, Spirifer, and Productus, Sow., Strygocephalus, Defr., and Magas; Thecidea; Strophomena; Pachytes; Dianchora; and Podopsis.

§ 2.

Shell non-symmetrical, irregular, constantly adherent. *Genera*, Orbicula, including Discina, Lam.; and Crania.

Order 2.

Rudista.

Genera, Spherulites; Hippurites; Radiolites; Birostrites; including Iodamia of Defr.; and Calceola.

Order 3.

Lamellibranchiata.

Family 1. Ostracea. *Genera*, Anomia; Placuna; Harpax; Ostrea; and Gryphæa.

Family 2. Subostracea (Ostrea, Linn.). *Genera*, Ostrea; Spondylus; Plicatula; Hinnites; Pecten, including Amusium and Pandora of Megerle, and Neithea of Drouet, Pedum; and Lima.

Family 3. Margaritacea. *Genera*, Vulsella; Malleus; Perna; Crenatula; Inoceramus; Catillus; Pulvinites; Gervillia; and Avicula, including Margaritiphora of Megerle Margarita, Leach, Meleagrina, Lam.

Family 4. Mytilacea. *Genera*, Mytilus, including Modiola and Lithodomus (Lithophaga of Megerle); Pinna.

Family 5. Polyodonta, or Arcacea (Arca, Linn.). *Genera*, Arca, including Trisis of Oken, and Cucullæa of Lam.; Pectunculus; and Nucula.

Family 6. Submytilacea. * (species with an epidermis and nacreous; freshwater). *Genera*, Anodonta, including Berpolis, Leach, Iridina, Lam., Dipsas of Leach, Alasmodonta of Say, and Cristaria of Schum.; Unio, including Hyria and Castalia of Lam. * * (species without an evident epidermis, not nacreous, and more or less pectinated; marine). Cardita, including Venericardia and Cypricardia of Lam.

Family 7. Chamacea. * (shell irregular). *Genera*, Chama, including Chamostrea of De Roissy; Diceras, Etheria.† * * (shell regular). Tridacna, including Hippopus; Isocardia; Trigonia, including Opis of Defr.

Family 8. Conchacea. § 1. Regular Conchacea with lateral distant teeth. *Genera*, Cardium, including Hemicardium; Donax, including Capsa, Lam.; Tellina, including Tellinides, Lam.; Lucina, including Loripes of Poli, Amphidesma of Lam., Fimbria of Megerle, Corbis of Cuv.; Cyclas, including Cornea, Corbicula, and Pisum of Megerle, Cyrena and Galathæa of Lam.; Cyprina; Mactra; and Erycina. § 2. Regular Conchacea without lateral distant teeth. Crassatella; Venus, including Arthemis of Poli, Venus, Cytheræa, and Crassina of Lam. (Astarte of Sowerby, Nicania, Leach), Triquetra of De Blainv., and Macoma of Leach. § 3. Irregular Conchacea; Venerupis, including Rupellaria of Fl. de Bell., and Petricola of Lam.; Coralliophaga; Clotho; and Ungulina.

Family 9. Pyloridea. § 1. Ligament internal. *Genera*, * Corbula; Sphæna; Osteodesma, including Rupicola of Fl. de Bell.; Thracia; Hemicyclostoma; and Anatina. * * Mya, including Erodona of Daudin; Lutricola, including Ligula of Leach, and Lutraria of Lam. § 2. Ligament external and convex. Psammocola, including Psammobia and Psammotea of Lam.; Soletellina; Sanguinolaria; Solecurtus; Solen; Solemya; Glycimera, including Myaconcha?; Panopæa; Saxicava; Byssomya; Rhomboides; Hiatella, including Biapholius of Leach; Gastrochæna; Clavagella; and Aspergillum.

Family 10. Adesmacea. *Genera*, Pholas, including Martesia of Leach; Teredina; Teredo; Fistulana; and Septaria.

Order 4.

Heterobranchiata.

Family 1. Ascidiacea (Ascidia, Linn.). Tribe 1. Simple Ascidians. *Genera*, Ascidia; Bipapillaria; Fodia. Tribe 2. Aggregated Ascidians, Pyura; Distoma, including Sigillina of Savign.; Botryllus, including Diazoma and Polyclina of Savign., and Polycyclus and Botryllus of Lam.; Synoicum, including Enoœlium, Didermum, and Aplidium of Savign., and Pulmonella of Lam.

Family 2. Salpacea. Tribe 1. Simple Salpians. *Genera*, Salpa, including the genera Monophore and Timorienne of Quoy and Gaimard. Tribe 2. Aggregated Salpians, Pyrosoma.

Sub-type.

MALENTOZOARIA.

Class I.

Nematopoda.

Family 1. Lepadicea. *Genera*, Lepas; Gymnolepas, including Clitia and Conia of Leach; Pentilepas, including Pentalasmis and Pollicipes of Leach; Polylepas, including Scalpellum of Leach; and Lithotrya.

---

† M. de Blainville, in his corrections, allows that Etheria will come better under the Submytilacea, according to the opinion of Mr. Sowerby.

Family 2. Balanidæ. (*Balanus*, Brug.) * Operculum articulated, and more or less vertical. Genera, Balanus, including Acasta of Leach; Octhosia; Conia, including Asemus of Ranzani; Creusia, including Pyrgoma of Savigny; and Chthalamus. * * Operculum not articulated, and more or less horizontal. Coronula, including Chelonobia of Leach, Cetopira and Diadema of Ranzani, and Tubicinella of Lam.

Liber II.

POLYPLAXIPHORA. (Chiton, Linn.)

Genera, Chiton, including Chitonellus of Lam., and Chitonellus of De Blainv.

Our limits will not allow us to do more than refer to the systems of Schumacher, Latreille, and Rang, though they will, the latter especially, which is in many respects a happy combination of the systems of Cuvier, Lamarck, and De Blainville, with some alterations, well repay the student for their perusal.

The organization of the animals above treated of will be found under the titles CEPHALOPODA, CONCHIFERA, GASTEROPODA, and other articles relating to them in this work.

MALACONOTUS. [SHRIKES.]

MALACOPTERY'GII, according to Cuvier, the second great division, or order, of osseous Fishes, the species of which are distinguished by all the rays of the fins being soft and cartilaginous, exhibiting minute articulations and often divided into small fibres at their extremities. It frequently happens however that the anterior ray of the dorsal or of the pectoral fins is hard and bony, a character observable in nearly all the species of the *Siluridæ* and in many belonging to other families.

The greater portion of the fishes of this order have the scales formed of simple laminæ and with smooth margins; in this respect differing from the species of the *Percidæ*, *Sciænidæ*, &c., in which the edges of the scales are pectinated or serrated. The *Pleuronectidæ*, or Flat-fishes, however, present the latter structure of scale, and yet, according to Cuvier, are placed in the Malacopterygii. M. Agassiz on this account removes this group to another section, and he also arranges the *Siluridæ* in another group, owing to the structure of their scales. [SILURIDÆ.]

The *Malacopterygii* are divided into three sections. First, the *Abdominales*, in which the ventral fins are situated in the abdomen, far behind the pectorals. In the second section (*Subbrachiales*) the ventral fins are situated immediately beneath the pectorals, and the pelvis is suspended to the bones of the shoulder. In the third section (*Apodes*) the ventrals are wanting.

The section *Abdominales* contains the following families:—1. *Cyprinidæ*, or fishes allied to the Carp; such as Barbel, Gudgeon, Tench, Bream, Roach, &c. 2. *Esocidæ*, of which the common Pike may be regarded as the type. 3. *Siluridæ*, a family of which there are no representatives in this country, at least not well authenticated. 4. *Salmonidæ*, or fishes of the Salmon tribe. 5. *Clupeidæ*, of which we have familiar examples in the Herring, Sprat, Whitebait, Pilchard, Shad, &c.

The section *Subbrachiales* contains the families *Gadidæ* (Cod-fish, Haddock, Whiting, Ling, &c.); the *Pleuronectidæ* or Flat-fishes, such as the Flounder, Halibut, Sole, &c.; the *Discoboli*, of which family the common Lump-sucker will furnish an example; and finally the *Echeneididæ*, constituting the genus of Remora.

The third section, *Apodes*, contains the Eels, Conger-eels, &c.

MALACORHYNCHUS. [DUCKS, vol. ix., p. 179.]

MALACO'STRACA (*Μαλακόστρακα*), a term employed by Aristotle to designate the *Crustacea* generally, but confined by Dr. Leach in his arrangement to the second order of the class.

The *Malacostraca* of Leach are divided into three tribes.

1. *Brachyuri*, including the families Canceridæ and Corystidæ.

2. *Macrouri*, including the families Paguridæ, Palinuridæ, Astacidæ, and Squillidæ.

3. *Gasteruri*, including the families Gnathidæ, Gammaridæ, Cymothoidæ, Caprellidæ, and Asellidæ.

MALACOTTA, Schumacher's name for a genus of Cirripedes, Otion of Leach.

MALACOZOA, or **MALACOZOARIA**. [MALACOLOGY, p. 309.]

MA'LAGA (the Μάλακα of Strabo, 156, *Casaub.*), the principal seaport of the province of Granada in Spain, is situated in 36° 43′ N. lat. and 4° 20′ W. long., in the bight of a bay on the coast of the Mediterranean. Inland from the city extends a spacious and fertile plain, called La Hoya, bounded by ranges of lofty mountains. The Guadalmedina, a mere brook in summer, but in winter a stream of considerable volume, enters the sea immediately to the west of the city.

Malaga is of great antiquity, and claims to have been founded eight or nine centuries B.C. by the Phœnicians, who gave it the name of 'Malaca,' or 'royal,' to intimate the estimation in which they held it. But of this high antiquity there is no evidence. W. Humboldt (*Prüfung der Untersuchungen über die Urbewohner Hispaniens*, &c.) says that Malaca is a pure Basque word, and signifies the 'side of a mountain.' It was possessed successively by the Carthaginians; by the Romans, who called it 'Malaca,' and made it a municipium and confederate city; by the Goths, and by the Arabs. For the first three centuries of the Moslem domination in Spain, Malaga was subject to the caliphs of Cordoba; but on the disruption of that caliphat it fell into the hands of one petty sovereign after another, till it was annexed, early in the thirteenth century, to the kingdom of Granada. In 1487 Ferdinand and Isabella wrested it from the Moors, after an obstinate siege of three months, during which the citizens endured the severest horrors of famine.

From the earliest ages, under all the nations who have possessed it, Malaga has been renowned for its commerce. At the present day it is the only flourishing city in the province of Andalucia. Its imports are broad-cloths, cottons, linens, spices, hardware, and cutlery. Its exports are much more considerable, and amount on the yearly average to more than 4,000,000 dollars, or about 1,000,000*l.* sterling. They consist principally of wine and fruits; the former, which was once well known in England as 'mountain,' is now almost wholly consumed by the United States and Spanish America; the latter are chiefly fresh grapes and raisins, vast quantities of which reach the English market, together with some figs, almonds, oranges, and lemons. The other exports are brandy, oil, saffron, vermicelli, barilla, and soap, which is the only manufacture of Malaga worthy of mention.

Malaga at present contains about 52,000 inhabitants, but it was much more populous in the time of the Moors. Though the streets are narrow, tortuous, wretchedly paved, and not very clean, the city has a gay and cheerful aspect, as the exteriors of the houses are whitewashed or stained a yellow ochre colour. Many of the roofs are flat, as in the East, and are surmounted by miradores, or square towers with open galleries, where the citizens enjoy the cool sea-breeze. The city is divided into six parishes, and has several colleges and public hospitals, an iron-foundry of very recent erection, and a tobacco-factory where 700 persons are daily employed in making cigars. There were also twenty-four convents, but these were suppressed in 1835. Malaga is an episcopal see, and possesses a cathedral, a light and handsome building in the Græco-Gothic style; it is nearly 400 feet long, 150 broad, 125 in height from the pavement to the roof, and is surmounted by a steeple 270 feet high. It contains few pictures of merit, but has some good specimens of the coloured wooden statuary in which the Spaniards excel. The alameda, or public promenade, is adorned with fountains and flowering shrubs, and flanked by private mansions of great splendour. The harbour of Malaga is spacious enough to accommodate a large fleet; it is protected on the east by a massy stone mole, five furlongs in length, terminated by a handsome lighthouse. Few remains of Roman architecture now exist in Malaga; those of Moorish buildings are numerous, and are interspersed through the city in gateways, towers, walls, houses, and fragments of mosques. But the grand boast of Malaga is the Moorish castle, built in 1279, and covering the slope of a hill immediately to the east of the city. It is of great extent, and is divided into the lower castle, or alcazaba, and the upper, or gibralfaro, so called by the Moors from a Roman pharos which is said to have stood on the crest of the hill. The whole displays in its ruinous condition the effects of the Christian artillery in the siege of 1487.

Malaga enjoys a warm and delightful climate, with a peculiarly dry and unclouded atmosphere. Provisions are abundant and cheap. The citizens are gay, courteous, and hospitable; and the females are renowned throughout Spain for their grace and beauty, sprightliness and humour. The lower orders of Malagueños are indolent, thievish, revengeful, and prone to commit assassination. Malaga gave birth in the twelfth century to Ibn Beithar, the naturalist, the Pliny of the Arabians.

MALAGRIDA. [JESUITS.]

MA'LALA, JOHN (called also Malela, or Malalas, or Malelas), was the author of a chronicle in the Greek language, in 18 books, which extends from the creation of the world to the reign of Justinian. The time in which he lived is uncertain. He must have been alive after the reign of Justinian, since he mentions the number of years which that emperor reigned. Hody, in his Prolegomena to the Oxford edition of this writer, endeavours to show that he lived in the ninth century; but this opinion has been controverted by Jortin, Gibbon, Reiske, and L. Dindorf, who maintain that he lived shortly after the reign of Justinian.

Malala is a Syriac word, signifying 'orator,' or 'rhetorician.' He is also called John of Antioch; but he must not be confounded with the John of Antioch who also wrote a chronicle, extracts from which have been preserved in a work of Constantine Porphyrogennetus, 'On Virtues and Vices.'

The chronicle of Malala was printed for the first time at Oxford, 1691, under the superintendence of Chilmead, who died however before the work was published. Hody prefixed a dissertation to that edition on the life and writings of Malala; and Bentley an appendix, in the form of a letter to Mill, in which he corrected numerous passages. Bentley's letter to Mill was reprinted at the end of Bentley's 'Emendationes in Menandri et Philemonis Reliquias,' Camb., 1713. The chronicle was also published at Venice in 1733; but the best edition is by L. Dindorf (Bonn, 1831), which contains the notes of Chilmead and Hody, as well as Bentley's letter to Mill.

(Hody's *Prolegomena*; Dindorf's *Preface*.)

MÄLARN, LAKE OF. [SWEDEN.]

MALATIA (or more correctly Malatiyah), a town of Asia Minor, about 38° 25′ N. lat. and 38° 20′ E. long., is built in a fine plain, about 15 miles from the banks of the Euphrates. About six miles south-west of it is the town of Aspúzi, to which the inhabitants of Malatiyah retire for the seven summer months, returning for the five winter months to Malatiyah. These towns, which may be considered as one, contained in 1836, 3923 families, 2800 of which were Turkish and 1123 Armenian. The town was formerly more populous, but plague, cholera, and the depredations of the Kurds have greatly reduced it. Aspúzi is situated on the side of a mountain in a forest of fruit-trees. Malatiyah is in a plain, which at present is nearly reduced to an uncultivated state. The antient walls are in ruins, and in most parts have fallen down; the houses have a mean appearance, and the shops in the bazar are mere mud-stalls. There are two well built mosques and two caravanserais, all in the Persian style of architecture. Malatiyah derives its present importance only from its being situated on the great caravan-road which leads from Sivas to Diar-bekr and Mozul, and from being one of the places to which the Kurds resort for the purpose of trade. (Brant, in the *London Geographical Journal*, vol. vi.)

MALAY PENINSULA constitutes the most southern extremity of the continent of Asia, extending between the Gulf of Bengal and the Straits of Malacca on the west, and the Gulf of Siam and the Chinese Sea on the east. It is united to the continent at its northern extremity. Its most southern points form the northern shores of the Straits of Singapore. Kwi Point, in the Gulf of Siam, and the mouth of the Tanasserim river, which enters the Gulf of Bengal, may be considered as constituting its northern boundary; they are situated near 12° N. lat. Cape Burus, the most southern promontory of Asia, in 1° 15′ N. lat., and Cape Romania, in 1° 17′, constitute the two extremities of the Straits of Singapore. The peninsula lies between 98° and 104° E. long. It is 750 miles long, with a width varying between 60 and 180 miles. Its surface may cover an area of about 80,000 square miles, or about 4000 square miles less than that of Great Britain.

The peninsula is traversed by a mountain-range, which is a continuation of the Samroiyet (*i.e.* three hundred peaks) mountains, which between 12° and 14° N. lat. separate the valley of the Tanasserim river from the streams which fall into the Gulf of Siam. This chain, which in this part rises in numerous peaks to the elevation of 3000 feet, sinks lower south of Kwi Point, where it traverses the isthmus of Krah, the narrowest part of the peninsula, between 8° and 12° N. lat. It appears that the mountain-range on this long isthmus, though of moderate elevation, occupies together with its offsets the whole country from one sea to the other, except at its southern extremity, where an extensive tract of alluvial land, enclosing the bay of Chai-ya, occurs on the shores of the Gulf of Siam.

The isthmus of Krah lies due north and south. At its southern extremity, between 8° and 9° N. lat., the Malay Peninsula turns to the south-east, and preserves this direction to its most southern point. Between 6° 30′ and 8° N. lat. the mountains seem to be higher than on the isthmus, but this fact is not established, as no European has ever traversed this country. The tract between 5° and 6° 30′ N. lat. appears to be the highest part of the mountain-range, the peak of Titch Bangsa, opposite the town of Queda, rising, according to Crawfurd, to 6000 feet. The mountains in this part occupy the greatest part of the country, leaving only a low level tract, about seven or eight miles in width, along the Gulf of Bengal, which is swampy and mostly covered with jungle, but when cultivated yields rich crops of rice. On the eastern coast the level tracts are probably more extensive, but the offsets of the mountains in some parts approach near the sea-shore, as Cape Patani and Rocky Point.

South of 5° N. lat. is the widest part of the peninsula, which is about 180 miles in breadth. The interior or mountain-region of this part is little known, but it is certain that it is less elevated than the country farther north, and the summits of the hills are more rounded. The level tract along the Straits of Malacca widens considerably, being about 18 miles in breadth north of 4° lat., and more than 20 miles in breadth south of that parallel; but along the sea-shore a few isolated hills rise to a moderate height, as Rachado Point and others. The range forming the watershed between the rivers which fall into the Straits of Malacca and the Chinese Sea does not occupy the centre of the peninsula, but is nearer the western than the eastern shores. The level country along the Chinese Sea is also, so far as is known, much more extensive south of the town of Pahang, and contains a lake, that of Braugh, 20 miles in circumference. On the eastern boundary of the district of Malacca is an elevated summit, the Gunong Leadang of the natives, and Mount Ophir of the Portuguese, whose summit is estimated to be 4000 feet high. It is 24 miles from the Straits. Proceeding farther south, the mountains subside into hills; but even along the Old Straits, which divide the island of Singapore from the continent, the country presents a rocky and elevated shore, and its surface is strongly undulating, though it can hardly be called hilly. Towards this extremity the level country along the Straits of Malacca and the Chinese Sea is of inconsiderable width.

The comparatively small width of this peninsula and the disposition of the mountain-range prevent the formation of considerable rivers. The largest which are known are the Muar river, which forms the southern boundary of the district of Malacca and falls into the strait of that name, and the Pahang river, which runs nearly north on the eastern side of the peninsula. Both rivers are navigable before they issue from the mountains, and are separated by a portage of not more than 300 yards. The Pahang river flows 200 miles under the name of Suruting, and falls into the lake of Braugh, from which it issues under the name of the Braugh river, but soon takes that of Pahang river. At its mouth, near Pahang, are four large islands, planted with cocoa-nut and palm trees. It is probable that there are other rivers, navigable at least for a considerable extent, but they are not known. The number of small rivers is very great, and there probably is no country better watered than this peninsula.

The climate differs on the eastern and western sides of the peninsula. The eastern resembles the coast of Coromandel and of Cochin China Proper, as the mountain-range interrupts the clouds brought by the south-west monsoon, during which period the dry season prevails. But the country is exposed to the full effects of the north-east monsoon and the wet season commences in the beginning of November and continues till March. The northern part of the western coast is exposed to the south-west monsoon, and in climate resembles Aracan, having its rainy season in our summer, and its dry season in our winter. The southern portion of the western coast differs in climate from all other countries in Southern Asia. It constitutes the eastern side of a large valley, running from north-west to south-east, in the centre of which the Straits of Malacca extend like a large river. On the north-east this valley is sheltered by the mountain-range which traverses the peninsula in its whole length, and on the south-west by that mountain-chain which extends along the south-western shores of the island of Sumatra. Thus this country, as well as the low eastern coast of Sumatra, is perfectly sheltered against both monsoons, the north-eastern and the south-western. In this country accordingly the regular succession of dry and wet seasons is unknown. Showers of rain fall in every month of the year, but more abundantly in our summer. They moderate the heat of the atmosphere, and maintain a vigorous vegetation. No gales are known to occur, and no winds except the sea and land breezes. The heat is not so insupportable as in other countries near the equator; and though during the day the sandy shores are heated to a great degree, the air is cooled sufficiently during the night. Though no meteorological observations on this country have been published, it is known that the range of the thermometer is comparatively very small; it seems to amount hardly to 10 or 12 degrees in the whole year.

The soil seems not to be distinguished by fertility, being in most places composed of a tough red clay, or of a black earth similar to peat; but in many places it yields rich crops of rice. Besides rice the inhabitants live on plantains and some other vegetables; also on fruits, in which this country, especially towards the south, surpasses all other countries. The cultivated fruits are chiefly pine-apples, mangosteens, durion, shaddocks, and oranges. As articles of commerce, pepper, cotton, and a little coffee are cultivated. The country is generally covered with high trees, even on part of the mountains, but the teak-tree does not occur. The variety of trees and plants is very great, but they have not been examined by botanists, except in a few places. Rattans are exported in great numbers.

Cattle are few in number, but buffaloes abound. No sheep are kept; hogs and fowls are plentiful. In the uncultivated tracts and woods tigers, leopards, and rhinoceroses are frequently met with, and sometimes elephants. Among the birds, that kind of swallow which makes the edible nests is the most remarkable. It occurs however chiefly on the islands which skirt the peninsula on the west, and perhaps also in some places on the western coast, where the rocks approach the sea-shore. Fish is extremely plentiful, and constitutes one of the most common articles of food.

The most important articles of commerce are from the mineral kingdom. Gold is found in all the rivers, and also got from mines. A sufficient quantity of this metal is collected to justify the name of Chersonesus Aurea, or the Golden Chersonese, which the antients gave to this country. Tin is still more abundant, and seems to occur in the whole range from the isthmus of Krah to the southern extremity, but not in the Samroiyet range, north of the isthmus. The quantity annually collected probably exceeds 40,000 peculs (1 pecul = 133¼ pounds), and the greatest part goes to Pulo Penang, Malacca, and Singapore: part is exported from the harbours on the Gulf of Siam to China. Other metals are not noticed.

The bulk of the population consists of Siamese and of Malays. The former occupy the isthmus of Krah and the districts north of 6° 40′ N. lat., and the latter the remainder of the peninsula. The Malays of this country have not attained that degree of civilisation which is found among the inhabitants of Sumatra and Java. They show little industry in cultivating the ground, and still less in the mechanical arts. Their principal occupation is fishing. [Malays.] The language of these nations is different. In the interior there are two other nations: the Jakong, or Benua, inhabit some wooded plains towards the southern extremity of the peninsula; they are of a copper-colour, their hair is straight, and their features resemble those of the Malays. They have no fixed habitations, and live by the produce of the chace. Crawfurd thinks that they are Malays in the lowest state of civilisation, an opinion which is supported by their language, which contains but few words that cannot be traced in the Malay language. In the interior, between 6° and 8°, live the Samangs, who seem to belong to the race commonly called the Australian negroes, which is found from the Adaman Islands on the west, to Papua, or New Guinea, on the east, as well as on the continent of Australia. They resemble the African negroes in their features, and have woolly hair. In stature however they are much shorter, their average height, according to Light, in Marsden's 'History of Sumatra,' not exceeding 4 feet 8 inches. They have no fixed habitations, they live in the forests and mountains on the produce of the chase, and eat every kind of animal food, even reptiles. They are extremely timid, and have little intercourse with their neighbours. The whole of the Malay peninsula is thinly inhabited, and many extensive districts in the interior are unpeopled. The whole population perhaps does not exceed one million.

The northern part of the peninsula, as far south as the bay of Chai-ya, is immediately subject to the king of Siam. On that bay are two harbours, called Chai-ya and Bandon, and on the opposite western coast the harbour of Phunga, or Pongo, from which a commercial road traverses the peninsula to Chai-ya and Bandon. The produce of the island of Junk Seylon, or Salanga, and also European goods, are transported from Phunga across the isthmus to Bandon and Chai-ya, and thence shipped to Bangkok. From the island of Kos Sammi, or Pulo Carnam, the Chinese fetch cotton and edible nests; ten or fifteen junks arrive annually for that purpose.

That portion of the peninsula which lies between the bay of Chai-ya and Cajoe Patani is partly governed by Malay sovereigns, dependent on the king of Siam, and partly belongs immediately to Siam. The town of Ligar is said to have 5000 inhabitants, Malays, Chinese, and Siamese. A few Chinese junks arrive annually here for cotton, tin, pepper, and rattans. The same articles, and in addition to them sapan-wood, are exported from the towns of Talung and Sungara, which lie opposite the mountainous island of Tantalem. A road begins at Talung which crosses the peninsula to the small town of Trang, and is passable for elephants. Patani is the most southern of the small kingdoms subject to Siam. It is more fertile and productive than the other Malay states. Its capital was once much visited by vessels from Hindustan in their voyages to Siam, Cochinchina, and China, but at present it is rarely resorted to. It has some intercourse with Singapore; it exports much rice and salt, and a little tin.

The kingdoms of Calantan and Tringano on the eastern, and that of Queda on the western side of the peninsula are only nominally dependent on Siam, and their commercial produce, consisting of gold, tin, and pepper, is brought to Singapore. Tringano, situated at the mouth of the little river Tringano, seems to be a considerable place. From Queda a commercial road, passable for elephants, leads across the peninsula to Sungora; this road is much frequented. Another communication connects the mouth of the river Muda in Queda with the town of Patani. For a considerable distance the goods are conveyed in boats on the river, but still this road is not much frequented. The British colony of Pulo Penang, or Prince of Wales Island, is partly situated within the kingdom of Queda. [Penang.] The town of Queda is a small place. Its commerce was formerly considerable, but has been nearly destroyed by the establishment on Prince of Wales Island. A few miles farther up is Alustar, a more populous place, and the favorite residence of the princes.

The southern extremity of the peninsula is divided between the kingdoms of Pahang and Johore on the eastern side, that of Rumbowe in the interior, and those of Salangore and Perak on the western coast, together with the British colony of Malacca. [Malacca.] These kingdoms are independent, and under the protection of the British. None of the commercial places in these states are of importance; they send their produce, consisting of gold, tin, and pepper, to Malacca and Singapore. Perak contains the most productive tin mines in the peninsula, and in Salangore also some rich tin mines have been opened, not far from Cape Rachado. The islands lying in the Chinese Sea, as far as the Nantnas, are subject to Johore. Between the towns of Malacca and Pahang there is a communication, which is much favoured by the water-carriage on the river Suruting, a branch of the Pahang river, and also on the Pahang.

(Marsden's *History of Sumatra;* Crawfurd's *Embassy to Siam and Cochin China;* Finlayson's *Journal of a Mission* *to Siam and Hué;* and *Notices of the Indian Archipelago*, &c., collected by J. H. Moor, Singapore, 1837.)

MALAYS, THE, are a nation of Southern Asia, who occupy the shores of the Malay Peninsula, and, if language may be taken as a proof of the fact, seem to have spread over all the islands from Madagascar on the west to Easter Island on the east. Almost all the languages spoken in the islands of the Indian Archipelago and in the Pacific contain a great number of words and expressions which evidently are derived from the Malay language, and the physical character of the people confirms the inference drawn from this circumstance. The great body of this nation however inhabit the larger islands of the Indian Archipelago.

In person the Malays are short, squat, and robust. The medium height of the men may be five feet two inches, and that of the women four feet eleven inches, or about four inches less than the average stature of Europeans. Their lower limbs are rather large and heavy, but not ill-formed. Their arms are rather fleshy than muscular. The face is of a round form, the mouth is wide, and the teeth remarkably fine. The chin is rather of a square form; the angles of the lower jaw are very prominent. The cheek-bones are high, and the cheek consequently rather hollow. The nose is short and small, never prominent, but never flat. The eyes are small, and always black. The complexion is generally brown, but varies a little in the different tribes: climate seems to have nothing to do with the colour. The fairest races are generally to the west, but some of them are on the equator. The hair is long, lank, harsh, and always black. Compared with Europeans and the nations of western Asia, the Malays must be considered an ill-looking people. In person and complexion they most resemble the inhabitants of Siam and Ava, but they differ considerably even from them, and are a very distinct people, with a striking likeness among themselves, and a marked dissimilarity from all other people.

Crawfurd, who has carefully examined the different languages of the Indian Archipelago, finds in them a great similarity in respect of pronunciation, grammatical structure, and idiom. Twenty consonants and five vowels are the greatest number which these languages generally admit, and only two diphthong sounds occur. The structure of these languages is very simple: the relations of nouns are marked by prepositions, the tenses of verbs by auxiliaries, the passive forms by the prefixing of particles, and the transitive forms by affixing particles. Many idiomatic phrases, though expressed by words differing in sound among different tribes, agree in the signification of the single words. These languages are rich in expressions for familiar objects, but poor in the expression of abstract ideas, particularly such as relate to the operations of the mind. For many moral ideas they have no expressions at all. Not less than five kinds of written character are known among the nations who inhabit the Indian Archipelago, the Arabic characters not included, which are in general use among the nations that speak the Malay language.

The Malays have made considerable progress in civilization; but more in the island of Java than on the other islands of the Indian Archipelago. They are well acquainted with agriculture and some of the mechanical arts. They have also made some progress in medicine and music. They are undoubtedly more civilized than any of the nations of southern Asia which inhabit the countries between China and Hindustan. The Malays have great mental activity, and eagerly apply themselves to commerce and navigation, but their navigation does not extend beyond the seas surrounding the Indian Archipelago. Being expert navigators in these seas, and being favoured by the great number of small inhabited islands, their daring spirit urges them to piracy. Various parts of the Indian Sea are thus made very dangerous for small vessels, but the Malay pirates rarely attack European ships. Most of the Malay tribes that inhabit the Indian Archipelago are Mohammedans, but they differ considerably from the Arabs in manners; their wives, for instance, are not secluded from society. They are very revengeful, and among the different ways of taking revenge is the extraordinary one of 'running a muck,' as it is called.

According to the traditional history of many of the Malay tribes, the country of Menangkabao, in the interior of Sumatra, is their original seat, and it is asserted that they first issued from it so late as 1160, and passed to the Malay Peninsula, where they built a town, called Singapura. Hence they are said to have spread over the lower parts of all the islands of the Archipelago. But when we consider how far the Malay tribes are scattered towards the east in the islands of the Pacific, this tradition seems very improbable. It may however refer to the introduction of the Mohammedan creed, as, according to Marsden, a Mohammedan is called in Sumatra a Malay, even when he belongs to one of the tribes which are not of Malay origin. In the larger islands the Malay population generally occupies only the lower tracts along the coast, and the original inhabitants have retired before them into the interior. On the smaller islands the original inhabitants have been extirpated by them.

(Marsden's *History of Sumatra;* and Crawfurd's *History of the Indian Archipelago.*)

MALCOLM I., king of Scots, was the son of King Donald IV., who died in the year 904. He succeeded to the throne when King Constantine III. abdicated, for the retirement of a monastery, in the year 944; and he appears to have reigned about ten years. The principal event of his reign was the cession of Cumbria by the English king to the king of Scots. In this it is said the English king resigned to Scotland what he found he could not easily retain, the border districts being, from the mixed character of the population, in a state of very frequent disturbance; and by the cession of these districts the English king hoped to secure the fealty and friendship of the king of Scots. Malcolm was slain by the men of Moray, in the north of Scotland, where he had marched to repress an insurrection in that quarter; but the precise time, place, or circumstance in which this event occurred, is not certain. He had two grandsons of the same name with himself; the one by his son King Duffus, the other by his other son King Kenneth III. The former was slain by his ambitious uncle Kenneth, and never mounted the throne.

MALCOLM II., king of Scots, was the son of King Kenneth III., and inheriting the ambitious spirit of his father, he set up a claim to the throne, in opposition to his cousin King Kenneth IV., and on the fall of the latter in a pitched battle between the partisans of the two princes, Malcolm succeeded in the year 1003. He reigned about thirty years, the greater part of which period was spent in warlike encounters with the Danes, who sought a settlement in the kingdom. It was in gratitude for a victory obtained over these pirates, that Malcolm founded and endowed a religious house at Mortlach, which afterwards became a bishopric, and at a still later period went to form, with other churches, the bishopric of Aberdeen; and on the same occasion he made many and various grants and oblations to the church and clergy. His piety was accordingly acknowledged and approved by the papal see. Malcolm is also said to have been a legislator, and there is a collection of laws which go by his name, but the authenticity of the *Leges Malcolmi* is disputed. Malcolm died in the year 1033; and there is still shown in the church-yard of Glammis, 'King Malcolm's grave-stone,' which is a rude mass, without any inscription, 16 feet high and 5 feet broad. He appears to have had no son, but only two daughters, both of whom were married. One of these was mother of King Duncan, who was killed near Elgin in 1039, by a stroke of 'treasonous malice.'

MALCOLM III., king of Scots, was the son of 'the gracious Duncan,' whose story has been immortalized in the pages of Shakspeare. On his father's death Malcolm fled into England; but after the fall of Macbeth, and that of his successor, he recovered his father's sceptre, and was declared king in the year 1057; and, as Chalmers reckons, in the thirty-third year of his own age. He is commonly known in history as *Malcolm Canmore*, or *Malcolm Great-head*, probably from the wisdom and prudence of his character. A contemporary bard gives him two epithets, the one implying that he had a handsome person, the other that he had a cheerful mind; and it appears that for a series of years his reign was undisturbed either by foreign or domestic enemies. The accession of William Rufus however proved the signal for hostilities between the two countries, and in an encounter with the English forces Malcolm was surprised by Earl Mowbray, and slain on the 30th of November, 1093, in about the seventieth year of his age.

MALCOLM IV., king of Scots, was the grandson of King David I., and on the death of that king, on the [illegible] of May, 1153, he succeeded to the throne, being then in the twelfth year of his age. The same year he was called on to repress the insurrection of Somerled, Lord of the Isles, a

Galwegian chief of such great influence, that when a peace with him was secured, the event was deemed of sufficient importance to form an epoch in the dating of Scottish charters. The standard of rebellion was afterwards raised in Galloway, and Malcolm was obliged to lead a great force against Fergus, the lord of that country, whom he at length subdued. Malcolm had also a struggle with the men of Moray, who affected independence; and in 1161 he compelled them to submit to his authority. The powerful Somerled also again rose, and prepared to make another attempt on the dominions of the Scottish king; but the latter by his vigour triumphed over all his adversaries. The period of his reign however was not of long duration; as he died of a lingering disease at Jedburgh, on the 9th of December, 1165, at the early age of twenty-four.

MALCOLM, SIR JOHN, G.C.B. and K.L.S., was born at Eskdale, in the county of Dumfries, in Scotland, in 1769. He was sent to India, when he was only thirteen, under the care of his maternal uncle Dr. Pasley, and was appointed a cadet on the Madras establishment. He returned to England in 1794, for the benefit of his health, but sailed again to India in the following year, and took an active part, as an infantry officer, in the war with the celebrated Tippoo. After the fall of Seringapatam he was appointed, jointly with Captain (afterwards Sir T.) Munro, secretary to the commissioners who were entrusted with the division of Mysore; and his prudence and abilities were already so highly estimated by the British government in India, that he was sent in the same year (1799) to Persia on affairs of the most important nature.

On his return from Persia, in 1801, he was appointed private secretary to the governor-general; but he was again sent to Persia in the following year, in consequence of the death of Hajee Kalleel Khan, the Persian ambassador, who was accidentally shot at Bombay. In February, 1803, he was nominated to the residency of Mysore, and joined the army of General Wellesley in his campaign against the Mahrattas; but in 1805 he was recalled to Bengal, where he was occupied in the performance of the most active and responsible political duties, and particularly in concluding treaties of alliance with several of the Indian princes.

In consequence of the extensive projects of Buonaparte, who was said to be meditating an invasion of India, and who had entered into an alliance with Persia, Malcolm was again sent to Persia in 1807, but was unable to obtain any advantages in favour of the British government. On his return to India, in 1808, he proceeded to his government at Mysore; but owing to a change in the policy of the Persian court, he was again appointed minister plenipotentiary to Persia, where he arrived in 1809, and was received in the most flattering and distinguished manner. On his departure in 1810, in consequence of the nomination of Sir Gore Ouseley as his majesty's ambassador at the Persian court, the shah conferred upon him the order of the Sun and Lion, and appointed him a Khan and sepahdar of the empire. Malcolm returned to England in 1812, and was knighted shortly after his arrival. In 1815 he published his 'History of Persia,' in 2 vols. 4to., which contained an account of the country from the earliest period to the time when the work was published. This work is extracted from native sources, and is the only account which we possess in the European languages of many portions of Persian history. D'Herbelot's narrative terminated with the reign of Shahrokh, in A.D. 1446. Malcolm's History is also valuable for the information it affords us respecting the religion, government, manners, and customs of the inhabitants of Persia in all periods of their history; and more particularly for his accurate account of the state of Persia in his own time, which he had obtained by personal observation and diligent inquiries in the country.

Malcolm returned to India in 1817, and was immediately on his arrival attached, as the governor-general's political agent, with the rank of brigadier-general, to the army under Sir T. Hislop in the Deccan. He served under this general, as second in command, in his campaigns against the Mahrattas and Pindarrees, and greatly distinguished himself in the decisive battle of Mehidpore, in which Holkar was completely routed. Mr. Canning, then president of the Board of Control, after moving the thanks of parliament to Sir T. Hislop, added, 'and to Sir J. Malcolm, who was second in command on that occasion, but who is second to no one in valour and conduct. The name of that gallant officer will be remembered in India as long as the British flag is hoisted in that country.'

After the conclusion of this war Sir J. Malcolm received the military and political command of Malwa and the adjoining provinces, where he remained four years. The central provinces of India were at that time almost in a state of anarchy; the plundering expeditions of the Mahrattas and Pindarries had reduced many fertile districts to complete deserts, and had thereby forced multitudes to adopt the same marauding mode of life; and the war, which had just been brought to a close, had thrown upon society thousands of soldiers who had been trained to every species of bloodshed and rapine. Too much praise cannot be attributed to the prudent and firm manner in which Sir J. Malcolm administered the government of these provinces: he was particularly successful in conciliating the affections of the natives, and reclaiming by mild and conciliatory means the remains of the Mahratta and Pindarry armies from their savage mode of life. When Bishop Heber visited this part of India, a few years afterwards, the inhabitants spoke of Sir J. Malcolm in the highest terms of admiration, and eagerly asked when they might expect his return. An interesting account of this part of India was published by Sir J. Malcolm in 1823, under the title of 'A Memoir of Central India, including Malwa and the adjoining Provinces; with the History and copious Illustrations of the past and present Condition of that Country.'

Sir J. Malcolm returned to England in 1821; and on his quitting Madras a general order was issued by the government, in which the following well-merited compliment is paid to him:—'His career has been unexampled; for no other servant of the Honourable Company has ever, during so long a period, been constantly employed in the conduct of such various and important military and political duties. His great talents were too well known to admit of their being confined to the range of service under his own presidency. The exercise of them under different situations has connected him with every presidency, and rendered him less the servant of any one of them than of the Indian empire at large.'

Sir J. Malcolm continued to remain in England till 1827, when he was appointed governor of Bombay; but he resigned this office at the end of three years, and again returned to England. He was elected, shortly afterwards, member of parliament for Launceston, and took an active part in the opposition to the Reform Bill. He died on the 31st of May, 1833, of an attack of paralysis. A monument has been erected to his memory in Westminster Abbey, and also an obelisk, 100 feet high, in his native town of Eskdale.

In addition to the works of Sir J. Malcolm which have been mentioned above, he also wrote an account of the 'Political History of India' from 1784 to 1823, in 2 vols. 8vo., 1826, and a 'Life of Lord Clive,' which was published after his death, in 1836.

(*Memoir of Sir John Malcolm*, in 'The United Service Journal,' 1833.)

MALDANIANS, or **MALDANIDÆ**, the second family of sedentary Annelids in Lamarck's system, including *Clymene* and *Dentalium*, which last is not an annelid, according to the latest and best authorities, but a mollusk. [DENTALIUM.] Savigny established the family.

MALDON, a corporate town of considerable antiquity, and a parliamentary borough, in the hundred of Dengie and county of Essex. The town, which is eight miles east from Chelmsford and thirty-four miles north-east from London, is on the right bank of the Chelmer, about a mile above its junction with the Blackwater river. It consists of two principal streets, at right angles to each other; and their *cruciform* figure has led some authors to suppose that the name of the town itself is derived from the Saxon *Maldune*, signifying a crossed hill. The circumstance of the town not being now in a flourishing condition is said to be mainly owing to the construction of a canal, called the 'new navigation,' which commences at Collier's Reach, one of the channels into which the Blackwater river is divided by Northey Island, and after passing through the village of Heybridge, joins the Chelmer above Maldon, and is thence continued to Chelmsford, and thus the transit trade to this town has been in a great measure lost. The haven is convenient, and vessels of 200 tons come up to the town during spring-tides. The foreign trade, which in 1839 amounted to 3929 tons inwards and 2199 tons outwards, is declining; but the coasting trade, which in the same year amounted to 69,159 tons inwards and 44,111 tons outwards, appears to be on the increase. In 1823 the receipts of the custom-house were 17,010*l.*; in 1832 they had declined to 7032*l.* The chief part of the property of the corporation has been alienated. The town-council consists of four aldermen and twelve councillors. The charters are numerous, and date from the reign of Henry II. (7th of October, 1155). The parish church of All Saints is a very antient edifice, surmounted by a triangular tower of singular appearance. For a description of its interior, and of the other antiquities of Maldon, the reader is referred to the first volume of Morant's 'History of Essex,' folio, 1768, pp. 327-337. The livings are a vicarage and a curacy, producing a net income of 319*l.* and 165*l.* a year respectively; the latter is in the patronage of the dean and chapter of Westminster. The population of the borough, in 1831, was 3831. The grammar-school was founded by Alderman Breeder in 1608. It has been endowed by several benefactors with funds and landed property; and Dr. Plume, archdeacon of Rochester, and founder of the Plumian professorship of astronomy and experimental philosophy at Cambridge, bequeathed to its use his valuable library of books. The librarian receives a salary of 40*l.* a year. Dr. Plume also established a scholarship of 6*l.* per annum at Christ College, Cambridge, to which boys from the grammar-schools of Chelmsford, Brentwood, and Maldon are successively eligible. Maldon has returned two members to parliament since the reign of Edward III.

(Wright's *History of the County of Essex*, 4to., 1833; *Corporation Reports*, &c.)

MALE FERN, the rhizoma, incorrectly termed root, of the Nephrodium Filix Mas (Richard), Aspidium Filix Mas (Smith), has been celebrated from antient times as an anthelmintic. The rootstock of young plants should be collected in spring or summer, and a fresh supply obtained every year, as a change occurs in the part a few months after being collected. It should be quickly dried, and preserved in glass or earthenware vessels in a dry place. The interior should exhibit a greenish colour, and possess a disagreeable odour, with a bitter, harsh, astringent taste.

It consists of an oil, which may be extracted by sulphuric æther; resin, tannin, sugar, starch, and woody fibre. The oil, which is of two distinct kinds, one pure, and the other united with resin and an extractive, is the active principle. Formerly a powder of the whole substance was administered, but as the dose of this is bulky, Peschier has recommended pills of the æthereal extract, which are found to be very efficacious against that kind of tape-worm which is denominated the *Bothriocephalus latus*, or broad tape-worm. It is scarcely possessed of any power over the Tænia solium. The former infests the small intestines of the inhabitants of Poland, Russia, Switzerland, and some districts of France, in all which countries the male fern has a high reputation as a remedy; but it is not much valued as an anthelmintic in Britain, the broad tape-worm being nearly unknown in this island, though the Tænia solium abounds.

The common mode of administering it is to give a certain number of pills at night, and a like number in the morning, followed by some brisk cathartic, as the male fern only kills, but does not expel the worm. [ANTHELMINTICS.]

MALEBRANCHE, NICOLAS, one of the most illustrious disciples of Des Cartes, who both gave to his master's views a wider development and imparted to them clearness and vivacity, was born at Paris, 1638. Of a sickly and deformed habit of body, Malebranche passed his early youth in retirement and the close study of languages and biblical literature. His attention was first directed to the pursuit of philosophy by accidentally meeting with the work of Des Cartes 'De Homine.' The perusal of this work is said to have excited his susceptible disposition to such a degree that he was several times forced to lay it aside on account of the violent palpitation of his heart. Abandoning his previous literary pursuits, he devoted ten years to the examination of the Cartesian philosophy, and he acquired the reputation of surpassing all his contemporaries in a knowledge of its true spirit and tendency. As the result of his philosophical meditations, Malebranche published, in 1673, the first book of the 'Recherche de la Vérité,' which was quickly followed by the other five. This work thus complete was greatly altered in the several subsequent editions: the most correct and complete edition is that which appeared three years before the author's death, which took place at Paris, in 1715.

The philosophical writings of Malebranche are a model of a style at once elegant and perspicuous, in which neither the clearness of the thought is sacrificed to the graces of composition, nor the ornaments of language to simplicity. If the profound originality of his ideas gained Malebranche any admirers, the novelty and boldness of his assumptions exposed him to much opposition. Among the most famous of his opponents were Foucher, the Jesuit Du Fertre, and Arnaud, who, like Malebranche, was also a member of the Oratory, and at one time his friend and associate.

The object of the 'Recherche de la Vérité' is partly logical and partly metaphysical. On the one hand it investigates the sources of human error, which are reduced to three general heads—sensation, imagination, and the pure intellect (esprit pur). On the other, it attempts to establish some universal method for the investigation and discovery of truth. The source of error however lies not in any imperfection of the cognitive faculties, nor in any incomplete or wrong employment of them, but in the will, which forms its own opinion of the objects presented to it. When, for instance, we see a light or feel warmth, that which is in either case seen or felt is certainly light and warmth, and they are actually perceived, and so far error is impossible; but when, as the will is free to do, it is maintained that the light and warmth of which the subject is percipient exist in the object without, then error arises. Now as all sensuous perceptions are accompanied by pleasure or pain, which chiefly move the will, sensation is the principal source of error, and especially of those false systems of morality which make the highest good to consist in pleasure: for the senses present to the mind nothing but a delusive good, whereas the only true and real good—the Deity—is cognisable by the pure intellect alone.

But the most distinctive point in the system of Malebranche is the assumption by which he explained the possibility of knowledge. For as he followed Des Cartes in making extension to be the essence of matter, and thought of mind, it was necessary for him to account for the possibility of the interaction of two such distinct natures as thought and extension. The existence of ideas in the mind is, according to Malebranche, a fact not requiring to be proved; from this fact however he denies that it follows of necessity that objects corresponding to those ideas do actually exist; for, he observes, the imagination often presents ideas and combinations of ideas which do not exist. Indeed there is no greater hindrance to truth and knowledge than the erroneous belief that ideas refer to actually existing objects. Now all ideas may be classed under two heads: they are either internal, *i.e.* thoughts properly so called, which are therefore mere modifications of the thinking soul; or they are relative to certain external objects of which the soul cannot be cognisant without the mediation of ideas. Now the latter refer to material or spiritual things. External spiritual things may however be perceived both immediately and also mediately by ideas, but the material only mediately, both because they are extended and there is no community between them and the simple spiritual nature of the mind, and because the mind cannot pass out to distant objects. Here Malebranche refutes the hypothesis of material effluxes which pass from bodies and enter through the sensuous organs. Because, he says, these effluvial images must partake of the nature of body, and therefore being extended, they would impede each other in the passage to the senses, since from the same point and at the same time an incalculable number of objects may be perceived. Moreover this hypothesis does not account for the perception of the different distances of objects. Malebranche proceeds, in the next place, to refute the supposition that the mind arbitrarily produces the ideas which it has of outward objects. This is as absurd as to suppose that a painter can delineate an animal which he has never seen or heard described. Equally untenable is the explanation of cognition by innate ideas. For the number of ideas which the mind may entertain is potentially infinite, and it is absurd to suppose that an infinity of ideas have been originally implanted in the mind, of which however most individual minds are actively conscious of a very few at the utmost. Besides, with such a supposition, the choice and selection of ideas would be inexplicable. Again, the supposition that at each operation of thought the ideas are created and presented by God, is contradicted by the fact that the mind can at all times think of whatever object it pleases, and that consequently an infinite number of ideas must, however obscurely, be always present to the mind. Lastly, Malebranche examines the opinion that the soul, in order to the perception of outward objects, requires nothing but itself, by the contemplation and perfect development of its own powers. But this would be to make man equal to Deity, who alone is capable of being cognisant of all things in this manner and by the spontaneous exercise of his own energies. After repeating these theories as the only ones worthy of examination of all that have been advanced to account for the matter Malebranche concludes, that we see all things in and by God (nous voyons tout en Dieu). God, as the creator of all, necessarily possesses within himself ideas of all things, since otherwise the creation of them would have been impossible: by his omnipresence and as the source of spirituality he is intimately connected with all spirits, for God may be called the place of all spirits, as space is that of whatever is corporeal. The soul therefore sees in God the works of God as far as it pleases him to reveal them to humanity.

The mind, consequently, as well as matter, possesses no more than a passive activity, and the Deity is the original cause of all their operations. As then truth consists only in certain combinations of these ideas, which are furnished to the mind from without and by a foreign cause, the only method of truth is demonstration and the analytical investigation of the implicit consequences of explicit ideas.

The other works of Malebranche were partly controversial and partly religious. Of the latter we may mention the 'Entretiens d'un Philosophe Chrétien et d'un Philosophe Chinois sur la Nature de Dieu,' Paris, 1708; 'De la Nature et de la Grace,' Amsterdam, 1680. The following are of a mystical character, blending religion with metaphysics:—'Traité de la Morale,' Rott., 1684; and 'Entretiens sur la Metaphysique et sur la Religion,' Rott., 1688. A complete edition of his works was published at Paris, 1712, in 11 vols. 12mo.

MALEDIVA ISLANDS, commonly called the Maldives, lie in the Indian Ocean, and extend nearly on one meridian from 7° 6′ N. lat. to 40′ S. lat., or nearly 550 miles; but in no part is the breadth of the chain supposed to exceed 50 miles in a direct line, although the most western limit of the most northern group, or Atoll, is in 72° 48′ E. long., and the most eastern boundary of the chain in 73° 48′ E. long. The most northern Atoll is about 350 miles from Cape Comorin, the nearest point of Hindustan. The appellation is derived from the language of Malabar, in which the Sanscrit *dwipa*, 'an island,' is corrupted into *diva*, and from the name of the largest of these islands, which is called Mali.

The sovereign of these islands stiles himself Sultan of the Thirteen Atolls and Twelve Thousand Islands, but Captain Owen believes the actual number of these islands to be more than treble or fourfold this number. They are enclosed and protected from the sea, which during the south-west monsoon is violently agitated, by narrow strips of coral-reefs, which surround them like a wall. This protecting wall in many places scarcely reaches the surface of the water; in other places it forms a long sandy beach, perhaps less than six feet above the level of the sea, and is either circular or oblong. Each of these circular enclosures contains breaks, which constitute convenient passages for vessels or boats to enter. The number of these coral reefs is fourteen, thirteen of which are situated to the north of the equator. They lie on a long sand-bank, to the edge of which their outer sides extend, and beyond them there are no soundings. The channels which divide these Atolls, or Atollons (for so they are called), are in some places deep and safe. They are passed by the vessels which are bound to the island of Ceylon or the Bay of Bengal, the Malediva Islands lying across the direct route to these places. Two of these navigable channels are south of the equator: the Addon, or south channel, is between Pona Molubque Atoll (the South Atoll) and the island of Adon, and is about five miles long and five leagues wide; and the Equatorial Channel is between the island of Adon and the Atoll Suadiva, which is ten leagues wide. North of the equator are first, the One and a Half Degree Channel, which is 17 leagues in breadth, and formed by the Sudiva Atoll and the Adoumatis Atoll; it is the widest and safest of all these channels, and frequently used by ships proceeding eastward in the westerly monsoon. Farther north is the Collomandous Channel, formed by the Adoumatis Atoll on the south, and the Collomandous Atoll on the north; it is only seven or eight miles wide, but it is safe. The most northern is the Cardiva Channel, which also seems to offer a safe passage, but it is not used at present, though it appears to have been much frequented two centuries ago.

Within the Atolls the sea is not agitated by storms, and there are always soundings in twenty or thirty fathoms water. The islands are generally situated along the enclosing coral-wall, the central part of the Atolls containing only few of them. The islands are all small; not many of them exceed a mile in length and breadth, and a few are less than half a mile. They are generally circular or lozenge-shaped. Many are mere narrow strips, 50 or 100 yards broad, forming a circle, which encloses a lower tract, filled up with broken coral rocks, and dry at spring tides. Within this ring there is sometimes a considerable depth of water, from one to ten fathoms, so that a perfect lagoon is formed. The highest part of the islands is from six to 14 feet above water. Their surface consists of sand, about three feet thick, the top part of which is mixed with vegetable matter, forming a black, light, sandy soil. Beneath the sand is a soft sand stone, resembling particles of beach-sand indurated. This sandstone is about two feet thick, below which depth it softens again to sand, and here fresh-water is found. All the inhabited islands have fresh water, and also some which are not inhabited.

All the islands are covered with a thick impenetrable jungle, among which there are many fine large trees, as the Indian banyan fig-tree, the candoo-tree, the bread-fruit-tree and others. The bamboo grows on some islands, but is scarce. On some of the islands are small plantations of Indian corn and sugar-cane. A little cotton is grown, from which a small quantity of cloth is made. Two kinds of millet are cultivated, but not extensively. The inhabitants live mostly on fish and the cocoa-nut palms, which are cultivated with care. They are of a very small species, none of the fruit being as large as a common tea-cup, and most of them much smaller; but the coir is fine, long, of a white texture, and very strong, and is exported to a considerable amount. A few cattle are only found on the Mali or Maldiva Atoll, but there are no sheep or goats, and no poultry, except the common fowl, which is abundant. A few cats are kept to keep the rats out of the houses, which are very numerous, and cause great damage to the cocoa-nut plantations. The 'flying fox,' as it is called in India, a large species of bat, is very common. Fish is very abundant, and salt-fish once constituted an article of export. Turtle are common. Cowries are collected and exported to a great amount.

The climate seems very pleasant all the year round, the range of the thermometer not being great; but we have no observations extending over a whole year. In December, January, and February, the thermometer ranges during the day from 80° to 84°; at night it falls to 78°. In this season there fall a few showers of rain. The easterly winds set in early in December, and seldom blow strong, but generally in pleasant light breezes. Towards the end of January they pass to the northward, and calms begin to be frequent. During the remainder of the year westerly and north-westerly winds are by far the most prevalent, and frequently stormy. The climate is not favourable to the health of Europeans.

The inhabitants are Mohammedans. It is not ascertained whether they belong to the Arab race or the inhabitants of the coast of Malabar. Two languages are in use among them; the common, which seems to be peculiar to the people, and the Arabic, as a learned language. They have also a peculiar alphabet, differing from the Arabic and from the Sanscrit. It is written from right to left, and the vowels are indicated by points, as in the Arabic. The whole population may amount to between 150,000 and 200,000. They are governed by a chief, called Sultan, who is proud of his dependence on the British at Ceylon, whither he sends an annual embassy, bearing presents of the products of the islands, and receiving others in return. He resides on the Mali or Maldiva Atoll, which contains the largest of the islands, called Mali; its circumference is about seven miles.

These islands were formerly annually visited by one or two vessels from Hindustan for cowries and other produce. At present, the inhabitants themselves bring their own goods in their boats to Bengal, which consist of cowries, coir, cocoa-nut oil, turtle-shell, and some smaller articles;

and they export from Bengal rice, which is not grown on the islands, sugar, silk stuffs, broad-cloth, hardware, and tobacco. They arrive at Calcutta in June or July with the south-western monsoon, and depart from that place in the middle of December with the north-east monsoon.

(Horsburgh, Owen, and Moresby, in the *London Geographical Journal*, vols. ii. and v.)

MALEIC ACID has already been described under the name of EQUISETIC ACID; the present appellation is given in consequence of its having been since procured by subjecting malic acid to heat. It is composed of—

One equivalent of Hydrogen	1
Four equivalents of Carbon	24
Three equivalents of Oxygen	24
Equivalent	49
The crystals contain one equivalent of water	9
Equivalent	58

MALENTOZOA'RIA, articulated Mollusca, the second subtype in the system of M. de Blainville. [MALACOLOGY, p. 324.]

MALESHERBES, CHRETIEN GUILLAUME DE LAMOIGNON, distinguished by his courage and misfortunes, the associate of Turgot and those illustrious statesmen who sought by moderate and beneficial reforms to prop the weakness of the old monarchy, was born at Paris, 16th Dec. 1721. His father was chancelier of Paris, and Malesherbes, after finishing the course of legal study, was first appointed deputy to the procureur-général. Shortly afterwards he was elected a counsellor of the parliament of Paris, and in 1750 president of the Cour des Aides. In this office, he on the one hand courageously resisted the extravagant expenditure of the court, and on the other put a stop to the frauds and peculations of the farmers-general of the revenue. When, in consequence of their opposition to the court, the parliaments were abolished by Louis XV., the Cour des Aides was also abrogated, and Malesherbes retired to his country-seat, and employed himself in benevolent plans for the education and improvement of his vassals. Upon the restoration of the constitutional courts of the parliaments by Louis XVI., Malesherbes resumed his duties as president of the Cour des Aides; and in the following year (1775) he was appointed minister of the king's household. Upon the retirement of Turgot, Malesherbes also tendered his resignation to the king, which was accepted. The interval between this date and the troubles which preceded the outbreak of the Revolution Malesherbes devoted to a tour of inspection through his native country, Switzerland, and Holland, acquainting himself with the state of industry and the arts, and carefully investigating the nature and efficiency of their public institutions. He was again invited by the king to aid him with his counsel in 1787; but finding that he had no power, and that his advice was not listened to, he again retired just before the meeting of the states-general. When Louis XVI. was brought to trial, Malesherbes claimed the honourable but dangerous post of his defender, and was associated with Tronchet and Desèze. The fearless intrepidity of Malesherbes entailed upon him the hatred and suspicions of the party in power, and, with several members of his family, he was cast into prison, condemned to death, and guillotined on the 22nd of April, 1794, meeting his fate with cheerfulness and resignation.

The works of Malesherbes, who was a member of the French Academy and of the Academy of Belles Lettres and Inscriptions, are mostly on subjects of natural history and rural economy. His 'Discours et Remonstrances,' printed in 1779, are still quoted as authorities on financial questions. His 'Mémoire sur la Liberté de la Presse' particularly deserves mention for the enlightened view which it takes upon this difficult question, the more especially as the tolerance and liberality which it advocates had been practised by himself when the surveillance of the press was entrusted to him. On this ground he incurred the censures of the ultra party, and La Harpe expressly ascribes the excessès of the Revolution to the facility of publication under Malesherbes' ministry of the press. After the Restoration a monument to the memory of Malesherbes was erected by Louis XVIII. in the hall of the Chamber of Justice, with the inscription, 'Strenue semper fidelis regi suo, in solio veritatem, præsidium in carcere attulit.'

MALESHERBIA'CEÆ, a natural order of polypetalous Exogens, with a tubular inflated inferior calyx, within the throat of which are inserted five petals, five or ten stamens, and a short rim or crown of the same nature as that of Passifloraceæ, but more rudimentary. The ovary is stipitate, superior, one-celled, with parietal or free placentation. The order is therefore nearly allied to Passifloraceæ, from which however it differs in habit. The species are in many cases remarkable for the beauty of their yellow or blue flowers, and have been cultivated in this country, their seeds having been brought from Chili. They are however seldom seen, and are of no known use. (Lindl., *Nat. Syst.*, ed. 2, 71.)

MALHERBE, FRANÇOIS DE, born in 1555, at Caen, in Normandy, of a noble family, studied first in his native town, and afterwards at Heidelberg and Basel. On his return to France, he accompanied Henri of Angoulême, son of Henri II., who went to Provence as governor in 1579, and remained attached to his household till that prince's death in 1585. During that period he married at Aix in Provence, and settled there. He afterwards served in the army during the wars of the League. In the year 1600 he wrote an ode on the arrival in France of Marie de Medicis, the wife of Henri IV. With this ode his poetical reputation began. In 1605, having come to Paris on private business, Henri IV. sent for him, praised his poetry, and provided him with the means of remaining at court. After the death of the king, his widow Marie de' Medicis gave him a pension in consequence of an ode which he addressed to her. In 1527 he had the misfortune to lose his only surviving son in a duel. He felt the loss severely, and took steps to bring the offenders to justice. He even wrote a letter to Louis XIII., in which he demanded satisfaction. This letter is published among his works. Malherbe having repaired to the camp before La Rochelle, where the court was then pressing the siege of that place, he fell ill, and died in a few days, in 1628, being 73 years of age.

Malherbe has been styled by competent judges the restorer of the French language and poetry. He had a delicate ear and a refined taste, and he was very careful in the choice of his expressions. The eulogium bestowed upon him by Boileau is well known:—

> 'Enfin Malherbe vint, et le premier en France
> Fit sentir dans les vers une juste cadence.'

Malherbe's poetry is more remarkable for gracefulness of expression than for power of thought. He was an elegant versifier rather than a real poet. (*Poésies de Malherbe, rangées par ordre chronologique, avec la Vie de l'Auteur*, Paris, 1776.)

MALIC ACID was discovered in 1785 by Scheele. It received its name from having been first obtained from the juice of apples, in which it exists in considerable quantity, and also, as has been since ascertained, in various other fruits, as cherries, raspberries, strawberries, in house-leek, and the berries of the sorbus or mountain-ash. Mr. Donovan, who procured it from the last-mentioned source, obtained it of so great purity that he supposed it to be a new and peculiar acid, which he called sorbic acid; but it has since been proved to be identical with the malic. A mucilaginous substance which accompanies the acid obtained from apples prevents its properties from being perfectly and readily developed.

Various processes have been proposed for procuring this acid, and they are generally complicated: the following is perhaps as good as any, and is proposed by Liebig:—add carbonate of lime, but not to perfect saturation, to the expressed juice of the sorbus; the solution is to be decomposed by nitrate of lead, which precipitates malate of lead: this, after washing with cold water, is to be heated with boiling dilute sulphuric acid, and the resulting mass with sulphuret of barium, by which there are formed sulphuret of lead and sulphate of barytes, while the clear liquor contains malic acid, to which ammonia is then added to convert it into bimalate of ammonia, which readily crystallizes; this salt is to be precipitated by acetate of lead, and the resulting malate of lead decomposed by hydrosulphuric acid: the clear liquor, separated from the sulphuret of lead, being evaporated by a gentle heat, yields crystals of malic acid, which are not however regular in their form. Malic acid is colourless, inodorous, very sour to the taste, and acts strongly on vegetable blues; in a moist air it is deliquescent; it is very soluble both in water and in alcohol. Nitric acid converts it into oxalic acid. Its saline compounds are called malates.

some of which exist in nature, as for example, supermalate of lime is found in the juice of the houseleek.

According to Liebig, malic and citric acids are isomeric bodies, both being composed of, when anhydrous,—

Two equivalents of Hydrogen	2
Four equivalents of Carbon	24
Four equivalents of Oxygen	32
Equivalent	58

The crystals contain one equivalent of water; whereas those of citric acid contain different proportions of it, according to the circumstances under which they are formed.

When malic acid is subjected to a heat of about 350° Fah., it is decomposed, and the results are two isomeric pyro-acids and water, which are the maleic or equisetic and the fumaric or pyromalic acids.

The malates are not an important class of salts: we shall mention the general properties of a few of them.

Malate of ammonia is a deliquescent salt, but the binmalate is crystallizable, unalterable in the air, and insoluble in alcohol. Malate of potash is a deliquescent mass; the supermalate forms crystals which are unalterable in the air and insoluble in alcohol. Malate of soda is a deliquescent mass, the supermalate crystallizes. Malate of lime is sparingly soluble in water, requiring 157 parts of it cold, and 65 when boiling; the hot solution deposits crystalline grains on cooling. It is stated to be more soluble in some saline solutions than in pure water: the supermalate occurs in houseleek and some varieties of *sedum*; it may be formed by adding acid to the neutral salt; by exposure to heat it fuses as a transparent varnish, which distinguishes it from other salts of lime and vegetable acids. It is soluble in water but insoluble in alcohol. Malate of magnesia yields crystals which are unalterable in the air and are soluble in twenty-eight parts of water; with excess of acid, a gummy deliquescent saline mass is formed. Malate of barytes, both neutral and acidulous, is soluble and gummy; an insoluble subsalt may also be formed. Malate of strontia is gummy and deliquescent, the supersalt is but slightly soluble, but more so in hot than in cold water; the hot solution deposits crystals on cooling. Of the metallic malates we shall state the properties of a few:—Zinc forms three different compounds with this acid; the neutral malate crystallizes in short four-sided prisms; it is soluble in 55 parts of cold water; by boiling water it is decomposed into a supersalt which dissolves, and a subsalt which is precipitated. Binmalate of zinc crystallizes in large regular octohedrons; the submalate is an insoluble white powder. Malate of peroxide of iron is a reddish brown-coloured deliquescent mass, soluble both in water and alcohol. Malate of copper, whether neutral or acidulous, dries so as to form a green varnish which is unalterable in the air. The malate of silver is a gummy mass, but the supermalate is a crystallizable salt, which readily separates as such from solution in water. Malate of lead is nearly insoluble in cold water, but dissolves in boiling water, and the solution on cooling deposits brilliant white crystalline scales of this salt.

MALICIOUS INJURIES TO PROPERTY. At common law, mischief perpetrated with whatever motive against the property of another was not punishable criminally, unless the act amounted to felony, was accompanied with a breach of the peace, or affected the public convenience. In other cases the offender was liable only to an action for damages at the suit of the party injured. But the legislature has, at different times, interposed to repress, by penal enactments, injuries to private property of an aggravated nature, committed with the malicious intention of injuring the owner of such property. The different statutory provisions against mischievous acts done wilfully and maliciously were modified, as well as consolidated, by 7 and 8 Geo. IV., c. 30, which also contains a provision rendering it immaterial whether the malice of the offender be against the owner of the property or otherwise.

By the third section of that statute it is made felony punishable by transportation for life or not less than seven years, or by imprisonment not exceeding four years, with or without whipping in the case of a male, to cut, break, or destroy, or damage with intent to destroy or to render useless, any goods or articles of silk, woollen, or linen, or of cotton, or in which any of those materials are mixed, or any frame-work-knitted piece, stocking, hose, or lace, in any stage of manufacture; to cut, break or destroy, or render useless any warp or shoot of silk, woollen, linen or cotton, or of any of those materials mixed with each other or with any other material; or looms, frames, machines, engines, racks, tackle, or implements prepared for or employed in manufacturing or preparing such goods; or to enter by force into any place with intent to commit any of these offences. By section 4, it is made felony punishable by transportation for seven years, or imprisonment not exceeding two years, with or without whipping in case of a male, to cut, break or destroy, or damage with intent to destroy or render useless, threshing machines, or machines or engines prepared for or employed in manufactures, except those manufactures, &c. injuries to which are more severely punishable under the 3rd section.

By the 6th and 7th sections it is made felony punishable by transportation for seven years, or by imprisonment not exceeding two years, with or without whipping in the case of a male, to cause water to be conveyed into mines, or subterraneous passages communicating therewith, or pull down, fill up, or obstruct air-ways, water-ways, drains, pits, levels, or shafts, with intent to destroy, damage, or hinder or delay the working of mines; or maliciously to pull down, or destroy, or damage with intent to destroy or render useless, steam-engines, or engines for sinking, draining, or working mines, or staiths, buildings, or erections used in conducting the business of mines or bridges, waggon-ways or trunks for conveying minerals from mines, whether completed or unfinished. By sect. 12 it is made felony punishable by transportation for life or not less than seven years, or by imprisonment not exceeding four years, with or without whipping in the case of a male, to break down or cut down sea-banks or sea-walls, or the banks or walls of rivers, canals, or marshes, whereby lands are overflowed or damaged, or in danger of being so; to throw down, level, or destroy locks, sluices, floodgates, or works on navigable rivers or canals. And by the same section it is made felony punishable by transportation for seven years, or by imprisonment not exceeding two years, with or without whipping in the case of a male, to cut off, draw up, or remove piles, chalk, or other materials fixed in the ground and used for securing sea-banks or sea-walls, or the banks or walls of rivers, canals, or marshes, or to open or draw up flood-gates, or to do other injury or mischief to navigable rivers or canals, with intent or so as to obstruct or prevent the carrying on or completing or maintaining the navigation.

It is made felony, punishable by transportation for life, or not less than seven years, or by imprisonment not exceeding four, with or without whipping in the case of a male, by the 13th section, to pull down or destroy public bridges, or to do any injury with intent or so as to render them dangerous or impassable; and by the 14th section, to cut or destroy hop-binds growing on poles in any hop-plantation. But now (by 7 Wm. IV. and 1 Vict., c. 90, s. 2) the punishment of the latter offence is made transportation not exceeding 15 years and not less than 10 years, or imprisonment not exceeding three. By 7 & 8 Geo. IV., c. 30, s. 14 it is a misdemeanor punishable accordingly [MISDEMEANOR] to throw down, level, or destroy turnpike-gates, or walls, chains, rails, posts, bars, or fences belonging to turnpike-gates set up to prevent passengers passing by without paying toll, or houses, buildings, or weighing-machines for the collection, ascertainment, or security of toll. The 15th section makes it a misdemeanor punishable by transportation for seven years, or by imprisonment not exceeding two years, with or without whipping in the case of a male, to break down or destroy dams of fish-ponds, or of water being private property, or in which is a private right of fishing, with intent to take or destroy fish, or so as thereby to cause the loss or destruction of fish, or to put lime or noxious materials in ponds with intent to destroy fish, or to break down or destroy dams of mill-ponds. By section 16 it is made felony to kill, maim, or wound cattle; but the punishment is reduced by 7 Will. IV. and 1 Vict., c. 90, s. 2, to transportation not exceeding 15 years and not less than 10, or to imprisonment not exceeding three. The provisions of this statute (7 & 8 Geo. IV., c. 30) relating to the destruction of trees, plants, &c. have been already noticed. [LARCENY.]

By section 17 it was made felony punishable by transportation for seven years, or by imprisonment not exceeding two, with or without whipping in the case of a male, to set fire to any crop of corn, grain, or pulse, whether standing or cut down, or to any part of a wood, coppice, or plantation, or to any heath, gorse, furze, or fern; and by 7 Wm. IV. and 1 Vict., c. 89, it is made felony punishable by transportation for life or not less than 15 years, or by imprisonment not exceeding three (sect. 10), to set fire to any stack of corn, grain, pulse, tares, straw, haulm, stubble, furze, heath, fern, hay, turf, peat, coals, charcoal, or any steer of wood, or (sect. 11) to set fire to any mine of coal or cannel coal.

The enactments in this statute with respect to the burning of houses, &c. [Arson] have been repealed; and now by 7 Wm. IV. and 1 Vict., c. 89, sect. 2, it is felony punishable by death to set fire to a dwelling-house, any person being therein, and by sect. 3 it is felony punishable by transportation for life, or not less than 15 years, or by imprisonment not exceeding three, to set fire to a church or chapel, or a chapel for the religious worship of dissenters, or to a house, stable, coach-house, outhouse, warehouse, office, shop, mill, malthouse, hop-oast, barn, or granary, or to a building used in carrying on trade or manufacture, whether in the possession of the offender or of any other person, with intent to injure or defraud any person.

For the protection of shipping against malicious mischief several statutory provisions have been made. By 1 and 2 Geo. IV., c. 75, sect. 11, it is felony punishable by transportation for seven years, or imprisonment for any number of years, to cut away, cast adrift, alter, deface, sink, or destroy, or do any act with intent to cut away, cast adrift, remove, alter, deface, sink, or destroy, or injure or conceal buoys, buoy-ropes, or marks belonging to ships or vessels, whether in distress or otherwise. By 7 Geo. IV., c. 30, sect. 10, it is made felony punishable by transportation for seven years, or by imprisonment not exceeding two, with or without whipping in the case of a male, to damage otherwise than by fire (which offence had been made capital by sect. 9) ships or vessels complete or unfinished, with intent to destroy them or to render them useless.

By 7 Wm. IV. and 1 Vict., c. 89, sect. 5, it is made felony punishable by death to exhibit false lights or signals with intent to bring any ship or vessel into danger, or to do any thing tending to the immediate loss or destruction of ships or vessels in distress. And by sect. 6 it is made felony punishable by transportation for life, or not less than 15 years, or by imprisonment not exceeding three years, to set fire to, cast away, or destroy ships or vessels, with intent to prejudice owners or part-owners of vessels or goods, or underwriters on ships, goods, or freight. And by the 4th sect. it is made felony punishable by death, to set fire to, cast away, or destroy any ship or vessel, either with intent to murder any person or whereby the life of any person shall be endangered.

Besides the criminal responsibility thus created in respect of the acts of spoliation above enumerated, the legislature has given summary relief to persons whose property has been subject to petty but wilful aggressions. The last enactment on this subject is 7 and 8 Geo. IV., c. 30, sect. 24, under which persons wilfully or maliciously committing damage, injury, or spoil, to or upon real or personal property, for which no remedy or punishment is specially provided by that act, are, on conviction before a justice of the peace, to forfeit and pay such sum of money as shall appear to him a reasonable compensation for the damage, injury, or spoil committed, not exceeding 5*l.*, to be paid, in the case of private property, to the party aggrieved, except where such party is examined in proof of the offence; and in such cases or in the case of property of a public nature, or wherein any public right is concerned, the money is to be applied towards the county-rate or borough-rate; and if such sums of money together with costs (if ordered) are not paid either immediately or within such period as the justice may appoint, the justice may commit the offender to the common gaol or house of correction, to be kept to hard labour for any term not exceeding two calendar months, unless such sum and costs be sooner paid. This enactment does not extend to any case where the party trespassing acted under a fair and reasonable supposition that he had a right to do the act complained of, or to any trespass, not being wilful and malicious, committed in hunting, fishing, or in the pursuit of game.

By the 28th section any person found committing any offence against this act, whether punishable upon indictment or upon summary conviction, may be immediately apprehended without a warrant, by any peace-officer, or the owner of the property injured, or his servant, or any person authorized by him, and forthwith taken before some neighbouring justice of the peace.

Those summary proceedings before magistrates must be commenced within three calendar months from the commission of the offence.

The provisions of the law of France with respect to mali- cious injuries to property are to be found in the 3rd secti of liv. iii. of the Code Pénal, entitled 'Destructions, D gradations, Dommages.' Capital punishment is denounc only against those who set fire to buildings, ships, wa houses, wood-yards (chantiers), forests, underwoods, or cr growing or cut down, or to any combustible matter plac so as to communicate fire thereto. Minor offences in fores are provided for by titre 12 of the Code Forestier.

MALINES. [Mechlin.]

MALLEABILITY is that property of certain met which admits of their being extended by the blows of hammer or by pressure. In this quality gold exceeds other metals: thus the gold-leaf sold in books is so ex- tremely thin, that less than 5 grains cover about 2 square inches, and the thickness of each leaf does n exceed $\frac{1}{200000}$th part of an inch. Metals which are mal able are also ductile, that is, they may be drawn into w [Metals.]

According to Dr. Thomson, malleability and duct seem to depend upon a certain quantity of latent heat the metals which possess these properties. During th hammering they become hot, sometimes even red hot, a after this many of them become brittle, owing to the for out of the latent heat which they contained. By annealin which consists in heating them artificially and allow them to cool slowly, the heat is restored, and they reco their malleability and ductility; and thus it is that i which has been made hot by hammering loses its mall bility, and cannot be again hammered till it has be annealed.

MALLEA'CEA, or **MA'LLEIDÆ**, a family of Monomy arian Conchifers according to the system of Lamarck, m the genera of which are to be found in the family *Mar ritacea* of De Blainville. They belong to the *Ostrac* Cuvier, and the Oxygones of Latreille. Lamarck ma the family consist of five genera only:—*Crenatula*, *Pern*, *Malleus*, *Avicula*, and *Meleagrina*.

Animal, with the *mantle* non-adherent, entirely open its whole circumference, without tube or particular open prolonged into irregular lobes, especially backwards: canaliculated, and almost always furnished with a byss

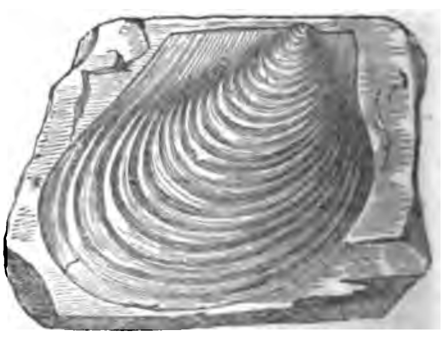
Shell black or horn colour, inequivalve, inequilater very irregular; *hinge* without teeth; marginal ligam sublinear, simple, or interrupted by crenulations; *mus* *impression* subcentral, fixed generally by a byssus f nished by the animal.

M. Rang places the fossil genus *Posidonia* at the b of the family, so that the position of that genus is appro mated to *Lima*, which is arranged as the last of the *P tinidæ*.

Genera. Posidonia (Bronn).

Animal unknown.

Shell very delicate, nearly membranous, equivalve, ine- quilateral, oblique, rounded, not gaping? cardinal b straight, a little prolonged on each side, so as to be aur lated; *hinge* toothless; no pit for the ligaments; passage for a byssus.



Posidonia (from specimens in Irish limestone).

M. Rang remarks that this genus had been rece (1829) established for impressions sufficiently commo the schists of Dillemburg, and which some naturalists been tempted to refer to rudimentary shells of Aplysia Pleurobranchus. M. Rang agrees with M. Bronn in opin that these are the impressions of bivalve shells, and assigns to *Posidonia* the position above stated. M. Deshayes however, in the last edition of Lamarck (1836), does not mention the genus among the Malleacea.

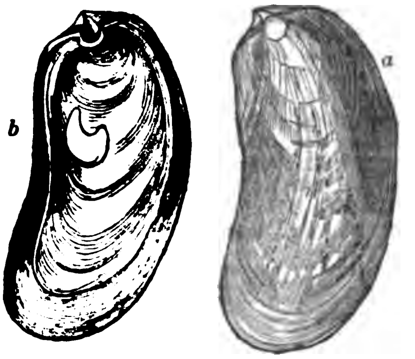
Vulsella. (Lam.)

Animal elongated, compressed; *mantle* very much prolonged backwards, and bordered with two rows of papillary tubercles which are very close set; *foot* small, canaliculated, without a byssus; mouth large, labial appendages very much developed and triangular; branchiæ narrow, very long, and united nearly throughout their extent.

Shell subcorneous, delicate, elongated, flattened, irregular, inequilateral, subequivalve, the umbones nearly anterior, distant, and a little recurved; *hinge* toothless, and offering simply on each valve a projecting callosity comprehending a pit for the insertion of the ligament; *muscular impression* subcentral.

Geographical Distribution of the Genus.—The seas of warm climates, where the species, none of which are furnished with a byssus, are found in *Alcyonia*, sponges, &c.

Example, *Vulsella lingulata. Locality.*—East Indian Ocean.



Vulsella lingulata.

a, Valves, closed; *b*, inside view of valve, showing the hinge and muscular impression.

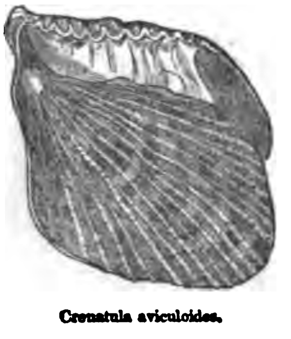
Crenatula. (Lam.)

Animal not known, but very probably bearing a close relation to that of Perna.

Shell foliated, flattened, subequivalve, inequilateral, irregular, a little gaping behind, but without any aperture for a byssus; *hinge* linear, marginal, marked with serial crenulations, which are callous and hollowed into rounded pits for the reception of the divisions of the ligament; muscular impression subcentral.

Geographical Distribution of the Genus.—The seas of warm climates, principally those of the East Indies and New Holland, as far as is yet known. The species, which are not numerous, are not fixed by their valves nor by a byssus, but, like the Vulsellæ, are found in submarine bodies, such as sponges, &c.

Example, *Crenatula aviculoïdes. Locality.*—Seas of America, especially those of the South.



Crenatula aviculoides.

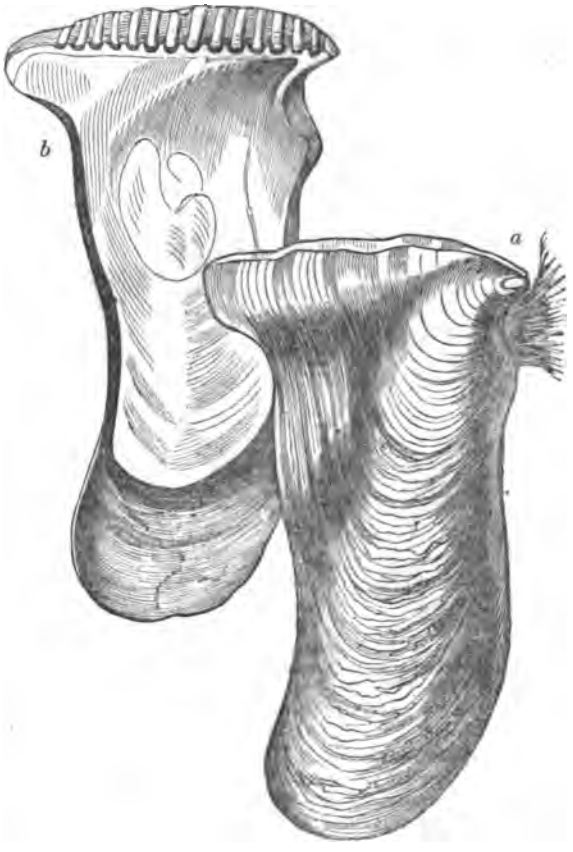
Perna. (Brug.)

Animal compressed; *mantle* very much prolonged backwards, and fringed at its lower border; *foot* very small, with a byssus.

Shell corneous or black, lamellar, very much flattened, subequivalve, inequilateral, very irregular, gaping in front for the passage of the byssus; *hinge* straight, marginal, having on each side a row of small parallel furrows, which are transverse, not intrant, and in which the divisions of the ligament are inserted; muscular impression subcentral.

Geographical Distribution of the Genus.—The seas of warm climates, more particularly those of the East Indies, though some species are found westward, as at the Antilles, Cape Verd, and the Azores. The species are moored to the rocks and mangrove trees by means of their byssus, and have been found at depths ranging from the surface to ten fathoms.

Example, *Perna Isognomum. Locality.*—East Indian Ocean.



Perna Isognomum.

a, Valves closed, showing the byssus; *b*, inside view of valve, showing hinge and muscular impression.

Malleus. (Lam.)

Animal considerably compressed; *mantle* prolonged backwards, and fringed with very small tentacular appendages; *foot* very distinct, canaliculated, and furnishing a byssus; buccal appendages spherico-triangular; *branchiæ* short and semicircular.

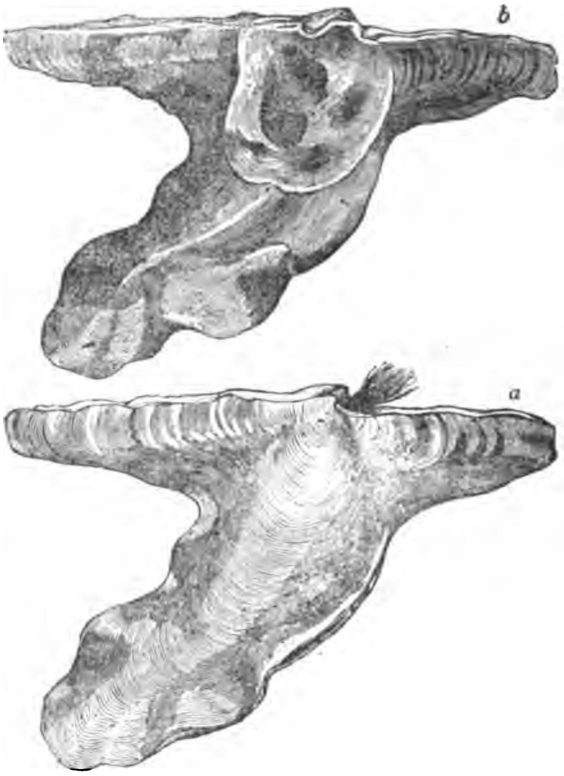
Shell foliated, black or corneous, subnacreous, subequivalve, inequilateral, very irregular, often auriculated, and presenting a hammer or T shape; umbones not distant; an oblique notch in front for the passage of a byssus; *hinge* linear, very long, toothless; with a conical oblique pit, partially external, for the reception of the ligament, which is triangular and subexternal; muscular impression of considerable size and subcentral.

Geographical Distribution of the Genus.—East and West Indies (Guadaloupe and Martinique) and Australasia. Found at depths ranging from the surface to seven fathoms. M. Rang speaks of the species from Guadaloupe and Martinique as having occurred at great depths. The species, which are not numerous, are moored by their byssus to submarine rocks, &c. They are very variable, and indeed M. Deshayes observes that he never saw any two individuals of a species alike. Age makes a considerable change in the shape of the shells, especially in the auricles.

M. de Blainville divides the genus into three sections:—1, consisting of species scarcely auriculated (*Malleus vulsellatus*); 2, consisting of uniauriculated species (*Malleus normalis*); and 3, consisting of biauriculated species (*Mal-*

leus vulgaris). M. Deshayes thinks that the greater part of the individuals occurring in collections under the name of *Malleus vulsellatus* may be the young of the variety of *Malleus vulgaris* with short ears, and he considers *Malleus vulsellatus* and *Malleus anatinus* as identical.

Example, *Malleus vulgaris*. *Locality*.—East Indian and South Seas.



Malleus vulgaris.

a, Valves closed, showing the byssus; *b*, inside view of valve, showing the hinge and muscular impression.

Gervillia (Fossil only).
(See the article, vol. xi.)

Inoceramus. (Parkinson.)—(Fossil only.)

See the article, vol. xii. Though some malacologists consider Inoceramus and Catillus to be identical, M. de Blainville, M. Rang, and M. Deshayes consider them as distinct species, and as belonging to this family. M. Deshayes gives the following description of *Inoceramus*.

Shell gryphoïd, inequivalve, irregular, subequilateral, with a lamellar shell, pointed anteriorly, and enlarged at its base; umbones opposed, pointed, and strongly recurved; *hinge* short, straight, narrow, and forming a right angle with the longitudinal axis, with a series of crenulations gradually smaller for the reception of a multiple ligament. Muscular impression unknown. The species are of moderate size.

Inoceramus sulcatus, nat. size; from the Folkstone blue marl. The smaller specimen shows the hinge of one valve, the other valve being a cast.

Localities.—Dr. Mantell records several species in the *Chalk*, two in the *Chalk-marl*, two in the Gault or Folkstone Marl, and one (from Martin) in the *Shanklin Sand* (Lower Green-sand). (*Organ. Remains of Sussex*, 'Geol. Trans.,' 1829.) N.B. Some of the species in the chalk—*Inocerami Brongniarti*, *Lamarckii*, and *Mytiloides*—are *Catilli*. Professor Phillips records three (one a *Catillus*) in the *White Chalk*, one in the *Red Chalk*, and one in the *Lias*. (*Geology of Yorkshire*.) Mr. Lonsdale notices two in the Lower Chalk (Oolitic District of Bath). Dr. Fitton records six named species and one undetermined from the *Upper Green-sand*, *Gault*, and *Lower Green-sand*. (*Strata between the Chalk and Oxford Oolite*, in *Geol. Trans.*, 1836.)

Example, *Inoceramus sulcatus*.

Catillus. (Brongn.)—(Fossil only.)

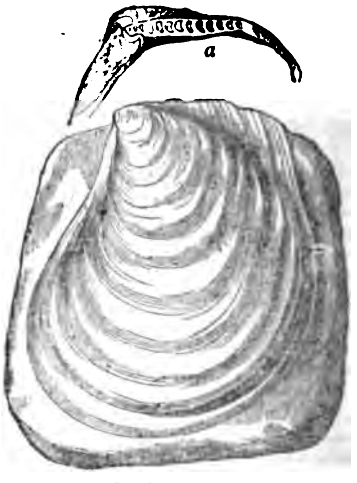
M. Deshayes thus defines Catillus, which is referred in this work from that title to **Margaritacea**; we however agree with the authors above quoted in thinking this the proper place for the genus.

Shell sometimes flattened, elongated, or suborbicular sometimes convex, cordiform, subequivalve, inequilateral with umbones more or less projecting. Hinge straight, a little oblique or perpendicular to the longitudinal axis, its border furnished with a row of small cavities which are very short and gradually increasing; structure of shell fibrous; muscular impression unknown.

M. Deshayes observes that among the genera proposed by Mr. Sowerby in his *Min. Con.* there is one to which he has given the name of *Pachymya*; this genus appears to M. Deshayes to possess all the external characters of *Catillus*, and he states that he has been led to remark the approximation of that genus to *Catillus* by studying a fine specimen in the collection of M. Duchastel. M. Deshayes proceeds to observe that M. Brongniart has established a genus under the name of *Mytiloïdes* for those *Catilli* which are very much elongated, and that consequently the genus *Mytiloïdes* cannot be retained. The genus *Catillus* then, as reformed by M. Deshayes, will consist of the genera *Pachymya*, *Mytiloïdes*, and *Catillus*. Some of the *Catilli* are of enormous size, and are mentioned as being of many feet in length. M. Deshayes thinks that the animals of *Inoceramus* and *Catillus* both wanted a byssus.

Localities.—The *White Chalk* in England and France.

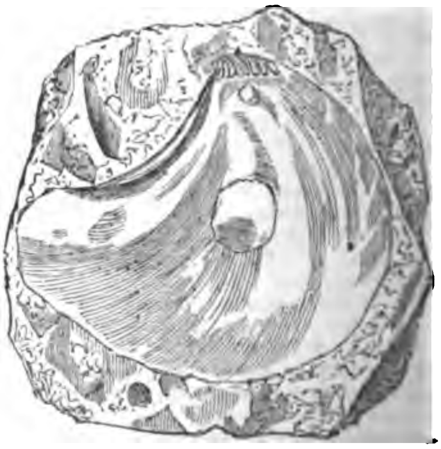
Example, *Catillus Cuvieri*.



Catillus Cuvieri.

a, The hinge.

Pulvinites. (Defrance.)—(Fossil only.)



Pulvinites Adansonii; inside view of valve.

Animal unknown.

Shell delicate, rounded, equivalve, subequilateral, with the umbones directed a little forwards; *hinge* composed of eight or ten divergent teeth, forming as many pits.

The genus *Avicula*, which is placed by Lamarck among his *Malleacea*, but is arranged by M. de Blainville with many of the genera above described, under his family *Margaritacea*, is separated by M. Rang into a family which immediately succeeds the Malleidae, under the name of *Aviculidae*, containing the subgenera *Avicula* (properly so called) and *Meleagrina*. (See the article AVICULA, vol. iii., to which we think it right to add the description of the animal by M. Deshayes.)

Animal oval, flattened, having the lobes of the *mantle* separated throughout their length, thickened, and fringed on the edges; body very small, having on each side a pair of large branchiae, nearly equal; mouth oval, rather large, with foliaceous lips, and with a pair of labial palps on each side, which are large and obliquely truncated; *foot* conical, vermiform, rather long, with a rather large byssus composed of stout filaments, united in some species at its base.

M. Deshayes also concurs in merging the genus *Meleagrina* in that of *Avicula*, which, according to M. Deshayes's observation of the genus, will contain also the fossil genus *Gervillia* of Bronn.

FOSSIL MALLEIDAE.

Those species which are fossil only are noticed above.

Vulsella.—M. Deshayes, in his Tables (Lyell), gives the number of recent species as five and one fossil (tertiary). In the last edition of Lamarck he makes the recent species six, with no addition to the fossil species. (Grignon, Lamarck, Paris, Deshayes.)

Perna.—The number of recent *Pernae* given by M. Deshayes in his Tables, amounts to ten recent and four fossil (tertiary). In the last edition of Lamarck, the same recent number is stated, but the fossil species amount to six (Virginia, Alsace, and the neighbourhood of Bèves, Italy, Hauteville, and Valognes, the Kimmeridge Clay, Germany and France, the Valenciennes and Bordeaux). Professor Phillips notes one (*Perna quadrata*, not mentioned by Lamarck or Deshayes) in the *Coralline Oolite* (Malton), and also in the *Bath Oolite*. He also notices a *Perna* in the Oxford Clay. (*Geology of Yorkshire*.) The genus is recorded in the *Inferior Oolite*, and in the *Coral Rag*, by Mr. Lonsdale (*Oolitic District of Bath*, in *Geol. Trans.*), and by Dr. Fitton in the *Lower Greensand* and the *Blackdown Sands*.

We have given a notice of the fossil *Aviculae*.

M. Deshayes, in his Tables, states the number of recent *Aviculae* (including *Meleagrinae*) at thirty, and gives five as the number of fossil (tertiary). In the last edition of Lamarck he makes the number of recent *Aviculae* twenty-one, and the number of fossil species six (Paris, Grignon, Senlis, &c., Chaumont, Paris Basin, Maestricht, and Cypli, the Cornbrash in England and France, the Middle and Upper Oolite in England and France, and the Muschelkalk in Germany, Lorraine, and Toulon). The *Meleagrinae* are two in number, both recent. Dr. Mantell mentions a species in the Chalk Marl. (*Organic Remains of Sussex*.) Professor Phillips records species in the Coralline Oolite and Calcareous Grit, in the Oxford Clay, Kelloways Rock, Bath Oolite, Inferior Oolite, and Marlstone. (*Geology of Yorkshire*.) Mr. Lonsdale notices species in the Lias, Inferior Oolite, Fuller's Earth, Bradford Clay, Cornbrash, and Kelloway Rock. (*Oolitic District of Bath*.) Professor Sedgwick and Mr. Murchison mention the genus among the Gosau Fossils. (*Geol. Trans.*) Dr. Fitton records species in the Upper Greensand, the Gault, the Lower Greensand, and the Portland Sand. ('Strata between the Chalk and Oxford Oolite,' *Geol. Trans.*) Mr. Murchison figures species from the Old Red-sandstone (tilestone and lower beds only), from the Upper Ludlow Rock, the Aymestry limestone, the lower Ludlow rock, the Wenlock Limestone, and the Caradoc Sandstone.

MALLET, DAVID, was born about the year 1700, at Crieff, in Perthshire, where his father, whose name was James Malloch, and who is said to have been one of the proscribed clan Macgregor, kept a small public-house. He is supposed to have been first sent to college at Aberdeen, but he afterwards studied at the university of Edinburgh; and he was attending the classes there and supporting himself by private teaching, after the custom of the Scotch students, when on the recommendation of the professors, he was appointed tutor to the sons of the Duke of Montrose, with whom he made the tour of Europe. He first became known as a writer by the publication of his ballad of 'Margaret's Ghost,' or, as it was originally entitled, 'William and Margaret,' which appeared anonymously in the 36th No. of Aaron Hill's 'Plain Dealer,' 24th July, 1724. There has been some controversy however as to Mallet's claim to more than the remodelling of this famous ballad. (See Percy's 'Reliques of ancient English Poetry,' 1794, vol. iii., 423-426, where the ballad is given in the shape in which it was finally published by Mallet, in his collected works, 1759; 'The Hive,' a collection of songs, vol. i., 1724, where, at p. 169, it is given as it had appeared the same year in the 'Plain Dealer;' 'The Hive,' vol. iii., published in 1726, where at p. 127, is given the other poem, which has occasioned the controversy as to the originality of Mallet's; and 'The Friends,' 1773, vol. i., where the attempt was first made to convict Mallet of plagiarism.) He now laid aside his paternal name, and took that of Mallet, which he probably imagined had more of an English sound and was better suited to his ambition to be taken for a native of South Britain; the earliest known mention of him under his new name in print is said to occur in 1726. In 1728 he published his poem of the 'Excursion,' in 2 cantos; and in 1731 his tragedy of 'Eurydice' was performed at Drury-lane, but very indifferently received. A poem entitled 'Verbal Criticism,' which he soon after produced, was of some importance to his fortunes by introducing him to the acquaintance of Pope, and through him to that of his friend Bolingbroke. Through these connexions he obtained the situation of private secretary to Frederick, prince of Wales, with a salary of 200*l.* In 1739 his tragedy of 'Mustapha' was acted at Drury-lane, with much applause, for the greater part of which however it was probably indebted to some satirical hits at the king and the minister Walpole. The next year, by command of the prince, he wrote, in conjunction with Thomson, the masque of 'Alfred,' which was performed in the gardens of Cliefden, in honour of the birthday of his royal highness's eldest daughter. It was afterwards entirely re-written by Mallet, and acted at Drury-lane, in 1751, with no great success. Of Mallet's remaining writings, the principal are, a 'Life of Bacon,' of very little merit, prefixed to an edition of Bacon's Works, in 1740; his poem of the 'Hermit, or Amyntor and Theodora,' 1747; and his tragedy of 'Elvira,' acted at Drury-lane in 1763. To this last a political meaning was at least ascribed by the public, and one that was not to the advantage of the play, for Mallet had now become a supporter of the unpopular administration of Lord Bute, who, soon after this, and, as it was said, by way of especial reward for this particular service, gave him a place in the Custom-house. Mallet was besides already in the receipt of a pension, which he had earned some years before from the duke of Newcastle's administration, by the assistance which he gave in directing the tide of the public rage against the unfortunate Admiral Byng. Two other transactions complete the history of his venal literary career: the first, his acceptance of a legacy of 1000*l.* left to him by Sarah, duchess of Marlborough, as the price of a Life of the great Duke, of which he never wrote a line; the second, his basely ungrateful attack upon his newly-deceased patron Pope, at the instigation of his living patron Bolingbroke, in the affair of the latter's 'Idea of a Patriot King.' [BOLINGBROKE, VISCOUNT.] It is believed however that he was in the end rather a loser than a gainer by Bolingbroke's bequest to him of the property of his works, which was his pay for this exposure of himself; he refused the bookseller's offer of 3000*l.* for the works, and then published them on his own account.

Mallet was an avowed freethinker or infidel, and indeed he does not seem to have had much principle of any kind. He was vain not only of his literary talents, but of his person, which, although short, is described as having been rather handsome before he became somewhat corpulent, and which he was accustomed to set off with all the advantages of dress. He appears to have made a considerable figure in society, and even Johnson admits that his conversation was spirited and elegant. He was twice married; first to a lady by whom he had, besides other children, a daughter, who married an Italian gentleman named Cilesia, and wrote a play called 'Almida,' acted at Drury-lane in 1771; secondly, to a Miss Elstob, by whom he got a fortune of 10,000*l.* He died possessed of considerable property, 21st

April, 1765. A collected edition of his poetical works was published by himself, in 3 vols. 8vo., in 1759.

MALLET, PIERRE HENRI, born at Geneva in 1730, became professor of belles-lettres at Copenhagen, where he wrote several works on the history and antiquities of Scandinavia. He was made member of the academy of Upsala, and became also correspondent of the Académie des Inscriptions of Paris. He afterwards returned to Geneva, and was appointed professor of history in the academy of that city. He died at an advanced age. His principal works are:—1, 'Introduction à l'Histoire du Danemarc,' Copenhagen, 1755; 2, 'Edda, ou Monumens de la Mythologie et de la Poesie des Celtes,' translated into English by Bishop Percy under the title of 'Northern Antiquities and the Edda,' 2 vols. 8vo., London, 1770; 3, 'De la Forme du Governement de la Suède,' 1756; 4, 'Histoire du Danemarc,' 3 vols. 4to., 1777; 5, 'Histoire de la Maison de Hesse;' 6, 'Histoire de la Maison de Brunswick.'

Mallet must not be confounded with Mallet du Pan, also a Genevese writer (born in 1750), who was well known for the various journals which he edited in Paris and London, and especially for his 'Mercure Britannique,' 1798-99, which, owing to the ability of the conductor and the energy of its language, was one of the most powerful organs of the Anti-Gallican press of that time.

MA'LLEUS. [MALLEACEA.]

MALLORCA, or **MAJORCA**, the largest of the Balearic Islands, is situated in the Mediterranean, off the eastern coast of Spain, to which kingdom it belongs. It lies between 39° 20′ and 40° 5′ N. lat., and between 2° 20′ and 3° 20′ E. long., about 110 miles from the coast of Catalonia and 120 from that of Valencia. It is nearly 60 miles long from east to west, and in some parts 40 broad from north to south: its circuit is 143 miles, and its area about 1410 square miles. The general surface of the country is hilly. On the north-west side a mountain-range crosses the island, the highest summit of which, the Puiz de Torellas, is above 4500 feet high. Another range of lofty hills runs parallel to this, through the heart of the island, and high grounds in many parts border on the coast. The eastern and southern districts are the most level in character. Some of the plains are liable to be inundated by the periodical rains, on which account they are generally used as pasture-land. Near Campos on the south, and near Alcudia on the north of the island, are marshy tracts which generate malaria to a very pernicious extent. The general aspect of the country is extremely beautiful and picturesque. The roads in the interior are very rugged and stony, and are traversed only by mules, which form the ordinary mode of conveyance, and by carts of clumsy and primitive construction, similar to those of Spain.

The climate of Mallorca is delightful, the winters being mild, though occasionally stormy, and the heats of summer being tempered by the sea-breezes and the vicinity of the mountains. The extreme fertility of the soil is mentioned by Strabo. Firs, holm-oaks, and wild olives adorn the slopes, and often cover the summits of the higher mountains; lavender, rosemary, thyme, marjoram, saffron, and roses perfume the air; and the valleys and level tracts produce in abundance corn, wine, oil, and fruit. The date-palm and the plantain attain their full size, though seldom yielding fruit. The valley most famed for beauty and fertility is that of Soler, 11 or 12 miles in circumference, abounding in orchards of orange and lemon trees, and hemmed in by mountains luxuriantly clothed with wood. The island is poorly watered, for though there are said to be no less than 210 streams, only two deserve the name of rivers. The larger of these is the Rierra, which falls into the sea beneath the ramparts of Palma, the capital. It is almost dry in summer, but in the rainy season it is very full and impetuous, and on several occasions in past ages has carried away great part of the city, and drowned many thousands of the inhabitants.

Mallorca produces wheat, barley, and oats, wines of excellent quality, olive oil in large quantities, hops, vegetables; fruits, particularly melons, oranges, and citrons, all of superior flavour; honey, hemp, wool, and a little silk. Sheep, goats, horned cattle, and pigs are numerous; poultry and game are abundant. In 1820 the productions of this island were valued at 53,000,000 reales, or about 560,000*l.* With the exception of a few foxes and hawks, the island is free from beasts and birds of prey; nor are there many venomous reptiles.

The geology of Mallorca is but imperfectly known. Granite and porphyry are said to be found, but the generality of the rocks are of secondary or tertiary formation. There is slate, fine marble of various colours, with abundance of sandstone, freestone, and chalk. Seams of coal have been discovered, but have not been worked. Coral is found in the bay of Alcudia. Salt is procured by the evaporation of sea-water in the low grounds about Campos; and in the same district is a warm sulphureous spring, famed for its efficacy in removing cutaneous complaints.

The original colonists of Mallorca were, according to Strabo, Phœnicians. The island fell with Spain successively into the hands of the Carthaginians and Romans. After being taken by Metellus, surnamed Balearicus, B.C. 123, a colony of 3000 Romans from Spain was established in the island. In A.D. 426 it was seized by the Vandals. In A.D. 798 it was conquered by the Arabs; and after being several times taken by the Christians and retaken by the Mohammedans, it was finally wrested from the latter in 1229 by James, king of Aragon; and since the union of the crowns of Castille and Aragon, it has remained subject to Spain.

The population, though much decreased since the time of the Moors, is still about 140,000. Palma and Alcudia are the only cities.

Palma, the capital, which was one of the two principal towns in the time of Strabo, is on the south-east of the island, picturesquely situated on a slope in the bight of a deep bay, ten or twelve miles wide, and formed by the capes Blanco and Cala Figuera. The city, though walled and fortified, could not sustain a regular siege. Its population is about 33,000. The streets are in some parts narrow and mean, in others wide and regular; the houses are large and without external ornament, mostly in the Moorish style of architecture, and many are built of marble. Palma is the see of a bishop, who is a suffragan of Valencia. The cathedral, a large Gothic edifice of much simple beauty, was built in the beginning of the thirteenth century by James of Aragon, surnamed the Conqueror, who is interred within its walls. Attached to the cathedral is a spire, of such remarkable delicacy and airiness, that it has received the name of 'The Angel's Tower.' There are many other religious edifices in Palma, five parish churches and numerous convents (recently suppressed), together with several hospitals and two colleges. Ferdinand V. founded a university here in 1483. The other public buildings are:—the episcopal palace; the royal palace, a very antient edifice, the residence of the captain-general, or governor of the island, comprehending also an arsenal, a magazine, and a prison; the town-hall; and the house of contractation, or of mercantile assembly and judicature, a Gothic edifice of remarkable beauty, but now serving only as a memento of the decayed fortunes of the city. Palma, though in the thirteenth century one of the chief markets of Europe, has now comparatively but little commerce. Its port is small, and will only admit vessels of little draught. Within and without the city are to be seen numerous evidences of the superior [illegible] population, and commercial importance of Palma in past ages.

Alcudia, the other city of Mallorca, is on the north-[illegible] coast, on a neck of land between the two bays of Alcudia and Pollenza. It stands on a rising ground, and is fortified with antient walls of great height. Some centuries ago it was a large and flourishing city, but is now in a wretched state of decay, with a population of only 1000 souls.

The other principal towns of Mallorca are:—Arta, with 8000 inhabitants; Manacor, with 7000 inhabitants; Pollenza (the Pollentia of Strabo), with 6000 inhabitants; Felanix, with 6000 inhabitants; Soler, Campos, Santani, San Marcial, Banalbufar, with 5000 inhabitants each; Andraix, with 4000 inhabitants; and Lluch Mayor, with 3500 inhabitants. There are other towns of smaller size, in all [illegible] two in number. There are also numerous villages.

The manufactures of Mallorca are linen cloths (coarse and fine), silk stuffs, and woollen goods, as tapestry, blankets, sashes, and corded stuff. Of the leaves of the palm are made brooms and baskets. The exports are oils, vegetables, fruits (fresh and dried), wines, brandy, cheeses, and woollen goods. Most of these are taken by Spain; but some by Sardinia, Malta, England, Holland, France, and even America. The imports, which in value bear a very small proportion to the exports, are corn, salted provisions, sugar, coffee, spices, tobacco, rice, cutlery and other [illegible] goods, and articles of clothing.

In character the Majorquins somewhat resemble the Catalans, but are less industrious and enterprising. They are much attached to their country, loyal to the government, and make excellent soldiers and sailors; they are bigoted and superstitious in religion, boastful, though mild and amiable in disposition, hospitable to strangers and prepossessing in their manners. The women are elegant, and fond of dress and ornaments. Castilian is spoken by the upper and middle classes, but the language of the lower orders is a mixed jargon of Limousin, Catalonian, and Arabic.

(Miñano, 167; [illegible]; Mariana, *Historia General de España*; Laborde, *Itinéraire Descriptif de l'Espagne*; Dameto and Mut, *History of the Balearic Kingdom*; St. Sauveur, *Travels through the Balearic and Pithiusian Islands*.)

MALLOW, the common name of the wild species of the genus Malva, the type of the natural order Malvaceæ. There are two common weeds of this genus, with flat, ribbed, monospermous fruits, enclosed in a valvate calyx, and not unlike a small round cheese, on which account they have in England the vulgar name of Cheeses, and in France of Fromageons. [MALVACEÆ.]

MALMAISON. [SEINE ET OISE.]

MALMESBURY. [WILTSHIRE.]

MALMESBURY, WILLIAM OF, one of the most valuable of our old historians, is said to have been born in Somersetshire, about 1095 or 1096: his father was a Norman, his mother an Englishwoman. When a boy he was placed in the monastery whence he derived his name, where, in due time, he became librarian, and, according to Leland, precentor, and ultimately refused the dignity of abbot. He is generally supposed to have died about 1143, though Sharpe, in his translation of Malmesbury's 'History of the Kings of England,' says it is probable that he survived this period some time, for his 'Modern History' terminates at the end of the year 1142; and it appears that he lived long enough after its publication to make many corrections, alterations, and insertions in that work, as well as in the other portions of his history. Some notion of his diligence may be afforded by the following list of his works:—1, 'De Gestis Regum' (the history of the kings of England). The first three books were probably written about 1120. After some delay he wrote the fourth and fifth books, which he dedicated to Robert, earl of Gloucester, at whose request he afterwards composed, 2, 'Historiæ Novellæ' (the modern history). This appears to have been begun after the death of Henry I. 3, 'De Gestis Pontificum' (the history of the prelates of England), containing, in four books, an account of the bishops and of the principal monasteries, from the conversion of the English by St. Austin to 1123, to which he added a fifth, *i.e.* 4, '*De Vita Aldhelmi*,' completed in 1125. 5, 'De Vita Dunstani,' in two books, extant in the Bodleian Library, MS. Rawlinson, 263, written at the request of the monks of Glastonbury. 6, 'Vita S. Patricii,' in two books, quoted by Leland in his 'Collectanea,' tom. iii., p. 272, but of which no manuscript is at present known, any more than of, 7, 'Vita S. Benigni.' 8, 'Passio S. Indracti,' MS., Bodley, Digby, 112. 9, 'De Antiquitate Glastoniensis Ecclesiæ,' addressed to Henry, bishop of Winchester, and of course written after 1129. 10, 'Vita S. Wulstani, Episcopi Wigorniensis,' a translation from the Anglo-Saxon, the greater part of which is published by Wharton in his 'Anglia Sacra.' 11, 'Chronica,' in three books, supposed to be lost. 12, 'Miracula S. Elfgifæ,' in metre. 13, 'Itinerarium Joannis Abbatis Meldunensis versus Romam,' drawn up after 1140, a manuscript of which was formerly in the possession of Bale. 14, 'Expositio Threnorum Hieremiæ,' MS. Bodley, 868. 15, 'De Miraculis Divæ Mariæ libri quatuor,' noticed by Leland in his 'Collectanea,' tom. iv., p. 155. 16, 'De Serie Evangelistarum,' in verse. This also is mentioned by Leland (ibid., p. 157), but neither this nor the preceding work is at present known in our manuscript libraries. 17, 'De Miraculis B. Andreæ,' MS., Cotton. Nero E. i. 18, 'Abbreviatio Amalarii de Ecclesiasticis Officiis,' MS., Lambeth, 380. 19, 'Epitome Historiæ Aimonis Floriacensis, MS., Bodley, Selden, Arch. B 32. This work contains an extract from the 'Breviarium Alaricianum,' or Visigoth Code, made by the author with the object of giving a view of the Roman law. ([illegible], c. 7, § 2.) 20, 'De Dictis et Factis memorabilibus Philosophorum,' Harl. MS. 3969. Tanner ascribes one or two other pieces to him.

William of Malmesbury's greater historical works, 'De Gestis Regum,' 'Novellæ,' and 'De Gestis Pontificum,' were published by Sir Henry Savile among the 'Scriptores post Bedam,' fol. 1596, reprinted, fol., Francof., 1601. A translation of the 'De Gestis Regum,' into English, by the Rev. John Sharpe, was published in 4to., London, 1815. Gale printed Malmesbury's 'Antiquities of Glastonbury,' and Wharton, as already noticed, published his 'Life of St. Aldhelm.'

An excellent feature of Malmesbury's literary character is his love of truth. He repeatedly declares that for the remoter periods of his historical works he had observed the greatest caution in throwing all responsibility for the facts on the authors from whom he derived them; and as to his own times he declares that he has recorded nothing that he had not either personally witnessed or learned from the most credible authority.

(Leland, *De Script. Brit.*; Tanner, *Bibl. Brit. Hib.*, pp. 503-506; Nicolson's *English Histor. Lib.*, edit. 1776, pp. 47, 52, 58; J. A. *Fabricii Bibl. Lat. med. et inf. ætatis*, 4to., Patav., 1754, tom. iii., p. 152; Sharpe's *Pref.* to his translation of William of Malmesbury *De Gestis Regum*.)

MALMÖ, a town in Sweden, in the province of Skane and the political division of Malmöhus, is situated about 55° 36' N. lat. and near 13° E. long. It is built on the widest part of the Sound, nearly opposite the town of Copenhagen, on level ground, and has a good and safe harbour, protected by the fortress of Malmöhus. The town is well built, and has regular streets. In the middle is a fine square, 125 yards long and 144 wide. The inhabitants, about 7000 in number, carry on an active commerce in corn, as Malmö is the principal commercial town of the fertile and rich province in which it is situated. It may also be counted among the manufacturing towns of Sweden, as there are several manufactories in which cloth, stockings, hats, gloves, carpets, soap, leather, starch, and looking-glasses are made. Some of these manufactories are rather extensive. It has a grammar-school and other schools for the poorer classes of society. (Forsell's *Statistik von Schweden*.)

MALMSEY, a luscious and high-flavoured wine made in the island of Madeira from grapes of a peculiar kind, which are suffered to attain the last stage of ripeness before they are gathered. Malmsey wine has much body, and will retain its good qualities for an indefinite period of time; in fact, it is improved materially by keeping. The quantity made is small, much smaller indeed than the demand, to supply which the wine-dealers are said to give factitious sweetness to common kinds of wine, which are then sold under the name of Malmsey. When newly made, Malmsey Madeira is of the same golden hue as the ordinary wine of the island, but its colour is materially deepened by age. Malmsey wine is also made in the island of Teneriffe, but the quality is greatly inferior to that of Madeira.

MALO, ST., a seaport in France, on the coast of the English Channel, capital of an arrondissement in the department of Ille et Vilaine. It is in 48° 39' N. lat. and 2° 1' W. long.; 194 miles from Paris in a direct line west by south, or 221 miles by the road through Dreux, Alençon, Mayenne, and Fougères.

A town called Aletum, in the neighbourhood of this place, existed in the time of the Romans, and is mentioned in the 'Notitia Imperii.' The inhabitants being continually exposed to the attacks of pirates, retired, in the eighth or ninth century, to a neighbouring rocky peninsula, on which they founded a town called St. Malo, from the name of the then bishop of Aletum. The site of the old town is indicated by the name of a headland, called by the Bretons *Guich Alet*. Before the Revolution, St. Malo was the seat of a bishopric.

The town of St. Malo is on a rocky peninsula on the eastern side of the estuary of the Rance, which opens into the roadstead of St. Malo. The peninsula is joined to the main by a causeway about 200 yards wide. A little distance to the south of St. Malo is the town of St. Servan, separated from St. Malo, to which in reality it forms a suburb, by the harbour, which is an inlet of the estuary. St. Malo is surrounded by walls and bastions, and defended on the north-west side by a castle built by Anne, duchess of Bretagne, and in other parts by five forts. The more modern part of the town is regularly laid out, and the ramparts afford pleasant walks. The principal public buildings are the ex-cathedral, the former episcopal palace, the exchange, and the theatre. The harbour, situated between the town, the isthmus, and the mainland, is commodious and safe. Vessels are left dry at low water: the depth at high water is 45 feet. The entrance is difficult from its narrowness, and from its being, as well as the roadstead, beset with rocks and shoals. There are two ports or docks, one of them for the navy, at St. Servan.

The population of St. Malo in 1831 was 9701 for the town, or 9981 for the commune; that of St. Servan 7665 for the town, 9975 for the commune: together 17,366 for the towns, or 19,956 for the communes. In 1836 the population of the commune of St. Malo was 9744. The inhabitants manufacture cordage, fishing-nets, and other utensils for the fisheries. There are ship-building yards, and a government snuff manufactory. Trade is not so brisk as formerly, perhaps through the diminution of the English smuggling trade. Considerable business is however done in wine, brandy, snuff, salt provisions, hemp, and pitch; in linens, which are sent to Spain; and in the agricultural produce of the surrounding country. There are depôts of salt and of colonial produce. There is one yearly fair, which lasts eight days. Many vessels are fitted out for the Indies, and for the whale and cod fisheries; and the coasting trade is very active. The sailors of St. Malo are among the best in France. In war-time many privateers are fitted out, the activity of which has drawn upon the town several attacks by the English.

There are two churches in St. Malo, beside the ex-cathedral and those in St. Servan; a foundling and a general hospital, a high-school, a free school for navigation, a drawing-school, and an agricultural society. There is a naval arsenal.

Jacques Cartier, the discoverer of Canada; the seaman Duguay-Trouin; Maupertuis, and La Mettrie, a physician who died in exile for doubting the immortality of the soul, were natives of this town.

The arrondissement of St. Malo comprehends 60 communes, and is divided into nine cantons, or districts under a justice of the peace: its area is 367 square miles: the population in 1831 was 120,561; in 1836, 118,243. The cultivation of tobacco is extensively carried on, and would be much more so but for the government restrictions.

MALONE, EDMOND, was born at Dublin in 1741. His father was one of the judges of the Court of Common Pleas in Ireland; and the subject of this notice, having taken a degree in the university of Dublin, was called to the Irish bar in 1767. Mr. Malone was however devoted to literary pursuits; and an independent fortune having devolved upon him, he took up his residence in London, and became an intimate of the more eminent literary men of that day, including Burke and Johnson. He subsequently became distinguished, principally as an editor of Shakspere. His first publication, connected with this his favourite subject, was that of a Supplement to Steevens's edition of 1778, in 2 vols. This contains Shakspere's sonnets and other poems, with notes, and the various plays which, by general consent, have been rejected from his works—we mean 'Sir John Oldcastle,' 'Locrine,' &c. It also includes 'Pericles,' which has subsequently found a place in the variorum editions. Malone displayed in this work many qualities which in some degree fitted him to be an editor of Shakspere's undoubted works; and in 1790 he brought out an edition of his own. He had previously contributed some notes to Steevens's edition of 1785. There were essential differences of opinion between Steevens and Malone, which would have rendered their co-operation perhaps impossible. Steevens carried his disregard of the authority of the texts of the old editions to an extravagant length; Malone, on the contrary, had a proper deference for that authority. Steevens, especially, despised the text of the first folio; Malone, in a much greater degree, respected it: Steevens was coarse and even prurient in his editorial remarks; Malone was cautious and inoffensive: Steevens had the more acuteness; Malone the greater common sense. As it was, Malone published a rival edition, and Steevens quarrelled with him for ever. In Malone's edition, his History of the Stage was, for the time at which it was written, a remarkable performance; and his Essay on the Genuineness of the three Plays of Henry VI. displays great critical sagacity and discrimination. The same qualifications which he exercised as an editor of Shakspere were equally exhibited in the part which he took in the controversies as to the genuineness of the Rowley poems, and the Shaksperian papers published by the Irelands. He was amongst the first to proclaim his belief that the poems attributed to Rowley were the production of Chatterton: and the imposition of William Henry Ireland was very clearly pointed out by him in a letter addressed to Lord Charlemont. This tract contains many interesting researches into our earlier literature, and is worth referring to, amidst the mass of nonsense which this controversy called forth. Malone also published, in 1797, the posthumous edition of the works of Sir Joshua Reynolds, with a memoir, he being one of that eminent man's executors. The remainder of his life was spent in adding to his notes on Shakspere, and preparing for a new edition, which he did not live to complete. His death took place in 1812, when he was in his seventy-first year. His posthumous edition of Shakspere, very carefully edited, was published by his friend Mr. James Boswell, in 1821, in 21 vols. Of Malone it is not, perhaps, very high praise to say that he was without doubt the best of the commentators on Shakspere. He is, compared with his predecessors, more trustworthy in his assertions, more cautious in his opinions, and more careful to interpret what he found in the text than to substitute his own conjectures. But he belonged to an age when the merits of Shakspere were not properly appreciated; and he is, like the rest of his brethren, cold and captious. He was of a critical school which, to a great extent, is fortunately extinct.

MALOPE, a genus of Malvaceous plants, consisting of two species, one of which is commonly cultivated as a favourite hardy annual. This plant, Malope malacoides, is common in Barbary, where it is found among stones and rocks, which it ornaments with its large crimson flowers: it is also met with in Sardinia and other parts of the south of Europe. The genus differs from Malva in having the carpels distinct, and heaped irregularly over a central receptacle, instead of being placed in a whorl and consolidated. Three or perhaps four other species are known to botanists.

MALOUINES. [Falkland Islands.]

MALPAS. [Cheshire.]

MALPIGHI, MARCELLUS, was born near Bologna in 1628. He studied medicine in that university, and in 1653 received his doctor's degree. His chief instructor in anatomy was Massari, at whose house he tells us that he and a few other select students were accustomed to meet in private, to dissect and discuss the important discoveries of the day. In 1656 he was appointed professor of medicine at Bologna, but soon after resigned on being invited to a similar office in the university of Pisa. Here he formed an intimate acquaintance with Borelli, the professor of mathematics in the same institution, to whom he often expressed his gratitude for the kindness and instruction which he received from him, though he doubtless repaid no small part of his obligations in the assistance which he gave to the valuable treatise 'De Motu Animalium.' Declining health obliged Malpighi to return to Bologna, but in 1666 he went to Messina, where he held the professorship of medicine for four years. He then again resided near Bologna till 1691, when he was summoned to Rome, and appointed chief physician and chamberlain to Innocent XII. In 1[illegible] he died of apoplexy.

Malpighi is now chiefly remembered in connection with his discoveries in the anatomy of the skin and of the secreting glands. He first described clearly the structure of the tongue, showing that it is at once a muscular and a sensitive organ; and he pointed out the fine papillæ on its surface as the seat of sensation. Imagining that he could perceive a structure in the skin analogous to that of the surface of the tongue, he examined the former tissue in several animals, and at length succeeded in demonstrating that it is everywhere beset with delicate conical papillæ as the chief organs of the touch. In the coloured portion of the tongue of the ox he had first discovered the rete mucosum, or, as it is often called in his honour, rete Malpighii; and he afterwards showed a similar membrane on the skin of the negro. He proved, as Riolan had before done, that the colour of the skin depends on this substance, the cutis of white and of coloured races being always of the same rosy hue. [Skin.]

On the subject of the structure of secreting glands, Malpighi was long engaged in a discussion with Ruysch, maintaining that all glands consisted of ducts terminating in simple acini, on which blood-vessels ramified without having any even communication with them; while Ruysch held that the blood-vessels were continued directly and with open orifices into the acini of the glands. The point was still debated when Müller's fine work, 'De Glandularum Structurâ,' proved that Malpighi, though incorrect in some details, was perfectly correct in the general view which he had taken of this structure. [GLAND.]

Malpighi was the first who examined the circulation with the microscope. He published also some excellent observations on the chemical and other characters of the blood; and his works on the process of incubation, and on the structure and physiology of plants, though now almost forgotten, must have been very important additions to the knowledge of his day.

Several editions were published both of his separate treatises and of his complete works: the titles of the most important are, 'Anatome Plantarum Idea'—'De Bombyce'—'De Formatione Pulli in Ovo'—'De Cerebro'—'De Linguâ'—'De externo Tactûs Organo'—'De Omento'—'De Structurâ Viscerum'—'De Polypo Cordis'—'De Structurâ Glandularum Conglobatarum.' The 'Opera Posthuma' were edited by Petrus Regis of Montpellier; they consist chiefly of a history of his discoveries and controversies, with which he has interwoven his own biography. Several of Malpighi's best works were addressed to the Royal Society of London, of which he was elected an honorary member in 1669, and was afterwards a constant correspondent.

MALPIGHIA'CEÆ, a natural order of exogenous plants, with polypetalous flowers, trigynous pistils, usually monadelphous stamens, and alternate exstipulate leaves, [illegible] various parts of the organs. They are usually shrubs or trees, and but seldom herbaceous plants. In addition to the more general characters already mentioned, they have in a majority of cases a pair of convex oval glands on the face of each sepal, and in many species the hairs are attached to the leaves, &c. by the middle; so that hairs of that description have acquired the name of *Malpighiaceous*. Many of them are beautiful objects, especially the Gaertneras and climbing species of Hiræa and Banisteria; a few only are useful. The bark of Malpighia Moureila and crassifolia is a kind of febrifuge. The fruit of Malpighia glabra is the Barbadoes Cherry of the West Indies; it varies in size from that of a large pea to a small cherry, is smooth, shining, and has three triangular stones; its flesh is juicy and sweet, but insipid. The fruit of Byrsonima coriacea, or Locust berry of the West Indies, is of much better quality; it is yellow, and contains a single stone. A few kinds produce timber of a bright yellow colour.

Malpighia coccigera.

1, a cluster of flowers, nearly natural size; 2, the stamens and pistil; 3, a transverse section of the ripe fruit.

The order is nearly related to the Aceraceæ, or Sycamores of cooler climates, differing in little except the ternary division of the fruit, the symmetrical flowers with unguiculate petals, and the pendulous or suspended seeds.

MALPLAQUET. [MARLBOROUGH, DUKE OF.]

MALT is grain, usually barley, which has become sweet and more soluble in water from the conversion of its starch into sugar by artificial germination to a certain extent, after which the process is stopped by the application of heat.

For the following short sketch of the process, which is called *malting*, we are chiefly indebted to a valuable work on 'Vegetable Chemistry,' recently published by Dr. Thomson, of Glasgow.

The barley is steeped in cold water for a period which (as regulated by law) must not be less than 40 hours; but beyond that period the steeping may be continued as long as it is thought proper. Here it imbibes moisture, and increases in bulk; at the same time a quantity of carbonic acid is emitted, and a part of the substance of the barley is dissolved by the steep-water. The proportion of water imbibed depends partly upon the barley, and partly on the length of time that it is steeped. From the average of a good many trials, it appears that the medium increase of weight from steeping may be reckoned 0·47; that is to say, every 100 pounds of barley when taken out of the steep weigh 147 pounds. The average increase of bulk is about a fifth; that is to say, 100 bushels of grain, after being steeped, swell to the bulk of 120 bushels. The carbonic acid emitted while the barley is in the steep is inconsiderable; and it is probable, from the experiments of Saussure, that it owes its formation, at least in part, to the oxygen held in solution by the steep-water.

The steep-water gradually acquires a yellow colour, and the peculiar smell and taste of water in which straw has been steeped. The quantity of matter which it holds in solution varies from $\frac{1}{50}$th to $\frac{1}{100}$th of the weight of barley. It consists chiefly of an extractive matter of a yellow colour and disagreeable bitter taste, which deliquesces in a moist atmosphere, and always contains a portion of nitrate of soda. It holds in solution most of the carbonic acid disengaged. This extractive matter is obviously derived from the husk of the barley, and is that substance to which the barley owes its colour. Accordingly grain becomes much paler by steeping.

After the grain has remained a sufficient time in the steep, the water is drained off, and the barley thrown out of the cistern upon the malt-floor, where it is formed into a heap called the *couch*, about 16 inches deep. In this situation it is allowed to remain about 26 hours. It is then turned by means of wooden shovels, and diminished a little in depth. This turning is repeated twice a day or oftener, and the grain is spread thinner and thinner, till at last its depth does not exceed a few inches.

When placed in a couch, it begins gradually to absorb oxygen from the atmosphere, and to convert it into carbonic acid, at first very slowly, but afterwards more rapidly. The temperature, at first the same with that of the external air, begins slowly to increase; and in about 96 hours the grain is at an average about 10° hotter than the surrounding atmosphere. At this time the grain, which had become dry on the surface, becomes again so moist that it will wet the hand, and exhales at the same time an agreeable odour, not unlike that of apples. The appearance of this moisture is called *sweating*. A small portion of alcohol appears to be volatilized at this period. The great object of the maltman is to keep the temperature from becoming excessive, which is effected by frequent turning. The temperature which it is wished to preserve varies from 55° to 62°, according to the different modes of malting pursued.

At the time of the sweating, the roots of the grains begin to appear, at first like a small white prominence at the bottom of each seed, which soon divides itself into three rootlets, and increases in length with very great rapidity, unless checked by turning the malt. About a day after the sprouting of the roots, the rudiments of the future stem, called *acrospire* by the maltsters, may be seen to lengthen. It rises from the same extremity of the seed with the root, and advancing within the husk, at last issues from the opposite end; but the process of malting is stopped before it has made such progress.

As the acrospire shoots along the grain, the appearance of the kernel, or mealy part of the corn, undergoes a considerable change. The glutinous and mucilaginous matter is taken up and removed, the colour becomes white, and the texture so loose that it crumbles to powder between the fingers. The object of malting is to produce this change: when it is accomplished, which takes place when the acrospire has come near to the end of the seed, the process is stopped by drying the malt upon the kiln. The temperature at first does not exceed 90°; but it is raised very slowly up to 140° or higher, according to circumstances. The malt is then cleared, to separate the rootlets, which are considered injurious.

Barley, by being converted into malt, generally increases two or three per cent. in bulk; and loses, at an average, about 20 per cent. in weight, of which 12 are ascribed to kiln-drying, and consist of water, which the barley would have lost had it been exposed to the same temperature; so that the real loss does not exceed 8 per cent. From many trials, made with as much attention to all the circumstances as possible, Dr. Thomson considers the following to be the way of accounting for this loss:—

Carried off by the steep-water .	1·5
Dissipated on the floor . .	3·0
Roots, separated by clearing .	3·0
Waste	0·5
	8·0

The loss on the floor ought, in Dr. Thomson's opinion, to be entirely owing to the separation of carbon by the oxygen of the atmosphere; but were this the only cause, it would be much smaller than three per cent., according to the same authority. Two other causes concur to produce this loss:—1. Many of the roots are broken off during the turning of the malt; these wither and are lost, while others grow in their place. 2. A certain portion of the seeds lose the power of germinating, by bruises and other accidents, and these lose a much greater portion than three per cent. of their real weight. After numerous careful trials, Dr. Thomson is disposed to conclude that the quantity of carbon separated during the whole process of malting, by the formation of carbonic acid gas, does not exceed two per cent., and that the weight of the roots formed amounts often to four per cent. These two, in reality, include the whole loss of weight which barley sustains when malted. What is lost in the steep, being husk, need scarcely be reckoned.

In the opinion of Dr. Thomson, the roots appear, from the process, to be formed chiefly from the mucilaginous and glutinous parts of the kernel. The starch is not employed in their formation, but undergoes a change, intended, no doubt, to fit it for the future nourishment of the plumule. It acquires a sweetish taste, and the property of forming a transparent solution with hot water. In short, it approaches somewhat to the nature of sugar, and is probably the same with the sugar into which starch is converted by boiling it with diluted sulphuric acid.

The following are the results of Dr. Thomson's analysis of barley and the malt made from it:—

	Barley.	Malt.
Gluten . .	3	1
Sugar . .	4	16
Gum . .	5	14
Starch . .	88	69
	100	100

In brewing ale, porter, and table-beer, three different kinds of malt are employed, which are known as pale and amber malts, brown or blown malt, and roasted or black malt, sometimes called patent malt. The pale or amber malt yields the saccharine or fermentable extract; the brown malt is not fermentable, but is employed to impart flavour; and the roasted malt is employed, instead of burnt sugar, merely to give colouring matter to porter.

The analysis of malt above stated is that of pale malt, whilst in the brown and roasted malts the sugar appears to be entirely converted into gum and colouring and extractive matters; and hence they are incapable of undergoing fermentation. The brown malt is subjected to a higher temperature in drying than the pale malt, and by a still further exposure to heat in revolving cylinders or roasters it is converted into black or patent malt.

Statistics.—Malt was first made to contribute to the public revenue in England in 1697. In Scotland the duty commenced in 1713, and in Ireland in 1785. The rate of duty, calculated on the imperial quarter, was in England 6$\frac{2}{11}$*d.* per bushel from 1697 to 1760; from the latter year to 1780 the duty was 9$\frac{9}{11}$*d.* per bushel; from 1780 to 1791 the duty was 1*s.* 4¼*d.*; it was then for a short time raised to 1*s.* 7½*d.*, but was lowered to 1*s.* 4¼*d.* again in 1793, and so continued till 1802, when it was raised to 2*s.* 5*d.*, and in the following year was further raised to 4*s.* 5¼*d.*, and so continued till 1816, when it was reduced to 2*s.* 5*d.* In [illegible] the duty was advanced to 3*s.* 7¼*d.*; in 1822 it was reduced to 2*s.* 7*d.*, and has continued at that rate until this time. In Scotland the duty from 1713 to 1726 was 6$\frac{2}{11}$*d.* per bushel; in 1726 it was reduced to one-half that rate until 1760; in 1780 it was again advanced to 8½*d.*; and in [illegible] to 11*d.*. In 1804 a distinction was made in the duty, according as the malt was made from barley or from bere or bigg, and thenceforward the rates have been as follows:—

		From Barley.		From Bere or Bigg.	
		s.	*d.*	*s.*	*d.*
1804	.	3	9½	3	1½
1816	.	1	8¾	1	8¾
1819	.	3	7¼	3	7¼
1820	.	3	7¼	3	1
1821	.	3	7¼	2	10
1822	.	2	7	2	0

There has not been any alteration since 1822.

In Ireland the duty first charged in 1785 was 7*d.* per bushel; in 1794 the rate was advanced to 9¼*d.*, and in the following year to 1*s.* 3*d.*; in 1798 to 1*s.* 5*d.*, and in [illegible] to 1*s.* 6½*d.* Further additions were made in 1803 to 1*s.* [illegible], in 1804 to 2*s.* 3½*d.*, in 1806 to 2*s.* 6¾*d.*, in 1813 to 3*s.* [illegible], and in 1815 to 4*s.* 5*d.* A reduction took place in [illegible] 2*s.* 4½*d.*; in 1826 the duty was again raised to 3*s.* 6¾*d.*, and [illegible] was again reduced in 1822 to 2*s.* 7*d.* The only alteration since was made in 1830, when the duty on malt from [illegible] was reduced to 2*s.* per bushel.

The quantity of Malt charged with duty in various years in the different divisions of the kingdom, and the amount of revenue received thereon, have been as follows:—

Years.	ENGLAND. Bushels.	SCOTLAND. Bushels.	IRELAND. Bushels.	Total. Bushels.	Duty. £.
1703	26,754,505	..	..	26,754,505	[illegible]

1832	31,669,771	3,714,334	2,006,350	37,390,455	[illegible]
1833	33,789,010	4,302,036	1,984,849	40,075,895	[illegible]
1834	34,449,646	4,491,292	2,204,658	41,145,596	[illegible]
1835	36,078,856	4,459,553	2,353,645	42,892,054	[illegible]
1836	37,196,997	4,903,187	2,287,535	44,387,719	[illegible]
1837	33,692,356	4,583,446	2,275,347	40,551,149	[illegible]
1838	33,823,985	4,419,141	2,262,440	40,505,566	[illegible]

It cannot fail to be observed, from these figures, that the increased consumption of malt in this country has borne a very inadequate proportion to the increase of the population. In the year 1730 the population of England and

Wales was 5,682,963, and it will be seen that the number of bushels of malt made for that use was within a very minute fraction of five bushels for each. In 1831 the numbers were 13,894,574, and the consumption of malt 32,619,570, being less than 2½ bushels for each. The reason for this comparative falling off is to be sought in our fiscal regulations. The rate of the duty was, in 1760, only one-fifth of the rate paid in 1831; and this alone would of course tend to check the consumption; but concurrently with this cause the importation of foreign-made malt has been prohibited; and as all the land in England fitted for the production of fine barley, such as is suited for the maltster, has long since been so applied, the consumption has been by that means starved, and the price enhanced so as to serve in aggravation of the high duty. The importation of barley from foreign countries is allowed under very high duties, fluctuating with the price of home produce; but under no state of the market can any addition be thus made to the quantity of malt in this country, because barley which has undergone a voyage of any length is unsuited to the process of malting.

MALTA.—*General Description.*—The Maltese islands, in the Mediterranean, lie between 35° 48′ and 36° N. lat., and 14° 10′ and 14° 36′ E. long. from Greenwich. Malta is 58 miles from the nearest point of Sicily, and 179 from Cape Bonn, the nearest point of the mainland of Africa. Its greatest length is 17½ miles, its greatest breadth is 9¼ miles, and its circuit, as a boat would sail round it, 44 miles. It contains two principal ports on the south-east side of the island, which are separated by a tongue of land a mile and a half long, on which are built the castle of St. Elmo and a lighthouse, commanding the entrance to both ports. This tongue of land (formerly called Mount Sceberras) is 200 feet above the level of the sea, but lowers towards the point, and is almost flat at the part where it joins the mainland. On this advantageous position is built the modern city of Valletta, which is the seat of government, and the citadel of the island. It is defended on all sides by the most stupendous fortifications, which no power commanding less abundant resources than the Knights of St. John of Jerusalem, who drew large revenues and sometimes contributions from the richest countries of Europe, almost for this express purpose, could have constructed. Other works situate on the opposite side of the great harbour are of nearly equal strength; amongst which is the powerful castle of St. Angelo, that flanks the entrance of the harbour, with four tiers of guns, the lowest of which are *à fleur d'eau*, corresponding to those, and completely forbidding every approach. Altogether the place is considered impregnable, which was proved by the fruitless endeavours of the British to expel the French garrison in 1798-1800.

When the British troops took possession of the place, after the capitulation of 1800, there were upwards of 800 pieces of ordnance mounted on the fortifications. The land front of Valletta is defended by a strong line of works, which stretch across from one port to the other, having within them two very high cavaliers, which command the town and country, and look into the works on the opposite sides of each harbour. This front is strengthened by a dry ditch running its whole length excavated in the rock to a depth varying from 90 to 140 feet. Outside the works of Valletta there is a suburb called Floriana, and beyond this is another line of fortifications, consisting of an interior and exterior line with a horn and crown-work in front of them. The total number of embrasures in the defences of Valletta and its environs, including the three cities, is 947; but as the cavaliers and some of the parapets are *en barbette*, it may be reckoned that the number of guns required to mount these works completely would be 1150. Many however are kept in store, and the embrasures at some points are rendered useless.

The great harbour, which is to the eastward of Valletta, is about 2500 yards in length with an entrance 450 yards wide, defended by a strong fort opposite the castle of St. Elmo, called Ricasoli, which crosses its fire, but is commanded by that castle. The harbour varies in width from 300 to 450 yards, without including three coves or inlets, which are of themselves ports and capable of containing many ships of war. In one of these is situate the naval arsenal, consisting of a rope-walk, the offices of the naval departments and extensive storehouses, which would contain all that is necessary for the fitting out of a very large fleet. On the opposite side of the same cove are handsome residences for the superintendent and officers of the arsenal, and spacious stores for the victualling department. Here also are three immense arches of masonry, under which the galleys of the Order were built, and drawn up for repair and for protection from the weather. All these buildings were constructed by the Order, and they have been greatly improved by the British government. On a prominent point opposite Valletta, called Bighi, stands the new naval hospital, which was built by a vote of parliament in 1830, and is one of the many striking objects which surround this beautiful harbour. The entrance of the port has no bar or other impediment, and the water is so deep that the largest ships can sail in close under the bastions of Valletta, direct to their anchorage. In the great harbour and its creeks five and twenty sail of the line have been known to lie during the last war without inconvenience, besides three or four hundred merchantmen. The only wind which renders it dangerous for boats to ply, or creates any uneasiness for the shipping, is the north-east, commonly called gregale, and that only when it blows hard; but there is good holding ground, and accidents seldom happen.

The harbour to the westward, which is called Marsamuscetto (a word signifying, in Arabic, 'a place of shelter'), has at its entrance, opposite to and beside the castle of St. Elmo, a small but powerful fort called Fort Tigné. It is principally appropriated to vessels arriving from the Levant or countries infected with the plague, and it is therefore commonly called the Quarantine harbour. Here is also the lazaretto, a suite of extensive buildings, built on an island in the centre of the harbour, with which have lately been united the spacious apartments of the square fort called Fort Manoel, on the same island; the whole forming the most complete quarantine establishment in the Mediterranean. In addition to its former accommodations a new plague-hospital is now nearly finished. Since the plague of 1813-14 no case of plague has occurred in the island, though many infected ships and crews have been received in this lazaretto.

Besides the harbours already mentioned there are several bays which ships sometimes enter in stress of weather, such as Marsa Scirocco, St. Thomas's Bay, and Marsa Scala, to the south-eastward of Valletta, and St. Julian's, St. Paul's, and Melleha, to the north-westward, on the shores of which, as well as on all parts of the island where a landing could be effected, small towers are erected, which under former governments served to give alarm in case of the appearance of an enemy, but are now only used to prevent smuggling and maintain the quarantine laws.

The whole of the south-west coast of the island is by nature inaccessible. The rocks rise perpendicularly from the sea to the height of several hundred feet. The island slopes from the southern to the northern side.

The small islands of Gozo, Comino, and Filfla belong to the group of the Maltese islands. The island of Gozo is about three miles and a half north-west of Malta. It is of an oval form, ten miles long by five and a half in breadth; it has no town or port on its coasts, and is only approachable by small craft. Its coasts are perpendicular on all sides, and it is studded with a few points of high land in the form of cones, one of which, being about 400 feet high, serves as a landmark to vessels coming from the westward. Between Malta and Gozo stands the little uninhabited island of Comino, in the channel between the two islands, which has a depth of water sufficient for the largest ships. This island is two miles long by one mile wide. Another small island, called Filfla, one mile and three-quarters south of Malta, is about a mile long and half a mile wide; it is a high perpendicular rock, also without inhabitants.

The general appearance of Malta and Gozo at sea is that of flat lands, the highest part of which is less than 600 feet above the level of the sea, and not visible at a greater distance than 24 miles. From being entirely calcareous rock, without any trees of large size, and a part of the year without any verdure whatever, the aspect of these islands is dreary and barren.

Particular Description.—The scene on entering the port of Malta is one of the most striking and beautiful that can be conceived. This magnificent harbour is surrounded with bastions, over which appear handsome buildings and the towers of numerous churches, all built of stone, and presenting the cleanest and most brilliant appearance. On one side stands the city of Valletta majestically towering above the harbour, and on the other the three cities of Vittoriosa, Cospicua, and Senglea (commonly called the Borgo, Burmola, and Isola), which in fact form one continued town, covering the two spits of land which project from the eastern side of the harbour like pointing fingers, and forming the inlets or coves already mentioned. Valletta and these three cities compose the capital of Malta; Valletta being the seat of the civil government, the military head-quarters, and the residence of the Maltese gentry and the principal merchants. The cities on the opposite side are inhabited chiefly by those who depend upon the naval arsenal and departments, ship-builders (who have several private yards there), and the proprietors of small craft, and traders with the neighbouring coasts. Valletta has a population of 28,000 souls; that of the three cities on the opposite side of the harbour amounts to 20,000, who have hourly and constant communication by row-boats, which pass and repass the harbour and add to its lively appearance. The three cities have their respective fortifications, which have all a connection, and serve to defend each other. The Cottonera works, which surround the whole on the land side, enclose a large tract of ground; they were intended by the Grand-master Cottoner as a shelter for the population of the country in case of invasion; but they were never finished, and have no advanced works.

The eastern part of the island is separated from the western by a ridge of land which crosses the island to the westward of Valletta, and forms a natural fortification. The island is thus divided into two parts, of which the eastern contain all the casals, or villages. On this line are several old entrenchments, behind which the troops and inhabitants fell back, when they were unable to prevent a disembarkation on the western part of the island; and if no hopes remained of arresting the progress of the enemy there, they retired upon Valletta, or into the Cottonera. These works, the principal of which are at Nasciar, are now useless, although they still continue to bound the populous part of the island, through the force of habit and the situation of the parish churches. This concentration of the population was caused by their former insecurity. In the days of the Order, no inhabitant trusted himself to sleep on the coast unprotected by walls of defence; but at present the general safety is such, that the pleasant villages of St. Julian's and Sliema have sprung up on the coast to the westward of Valletta, where the inhabitants of the capital have built country-houses, and enjoy the summer breeze without any fear of being dragged from their beds into slavery. Although the western division of the island contains no towns, and scarcely any habitations, there is much land under cultivation, and the wild thyme and other odoriferous plants, which abound in these parts, produce the honey for which Malta has always been so famous. There are also considerable salt-works here, which are the property of the government. From Nasciar there is a fine and extensive prospect over this end of the island, which takes in Comino and Gozo.

In the eastern division are the antient capital and 22 casals or villages. Città Vecchia, or the old city, as it is commonly called, but the proper name of which is Città Notabile,* is situate on a rising ground in the interior of the island, about six miles from Valletta, and was, before the foundation of the latter city, the capital of the island. It is still the seat of the bishopric, and contains the cathedral, a handsome modern edifice, built on the site of the antient church. The city is walled, but is of no importance as a fortification. It contains many good and even magnificent buildings, but, with the exception of two large convents, the population is very trifling. A populous suburb, called the Rabbato, is inhabited by the dependents of many convents and ecclesiastical establishments in the neighbourhood, and by a large agricultural population. The catacombs cut in the calcareous rock are said to be very extensive, but are only partially open, the passages being walled up to prevent the curious from losing themselves; their origin and purpose are unknown, but they appear to be of great antiquity. The parish churches of the casals are large and magnificent: they are built of the stone of the island, and being isolated and well situated in the centre of the habitations, display their architecture to advantage. The attachment of the Maltese to their religion, and their fondness for its form[illegible] induce them to make great sacrifices for the maint[illegible] of their churches, which are richly decorated. There [illegible] many large towns on the Continent, and even in It[illegible] where the cathedrals are not more splendid than som[illegible] these village churches, which form a striking contrast [illegible] the poverty and simple mode of life of the village pop[illegible]tion.

There are no streams in Malta, and but few springs. T[illegible] rain-water is collected in tanks, which are carefully excavated in the rock, and lined with a cement of pozz[illegible]lana; in ordinary seasons the tanks in the country are sufficient for agricultural purposes. The inhabitants of Valletta and the shipping are supplied with water by me[illegible] an aqueduct which conveys it from springs in the south[illegible] part of the island, and supplies all the lands in its pas[illegible] In seasons of great drought however the water is sca[illegible] This magnificent work of the Grand-Master Wigna[illegible] was built in 1616; it is eight miles and a half long, in [illegible] parts supported on arches, and on others running underground.

Gozo contains six casals, and in the centre of the isl[illegible] on a considerable eminence, about four miles distant [illegible] Migiarro, the principal landing-place, is a very old ca[illegible] the works of which are in a ruinous state. The inhab[illegible] of the island, before the construction of towers on the c[illegible] were obliged to retire every night within the precin[illegible] these fortifications to protect themselves from the Bar[illegible] corsairs. At the foot of this castle is a populous t[illegible] called the Rabbato. Gozo is more fertile than Malta. [illegible] surface is more undulating, and its gardens are riche[illegible] produces a great quantity of fruit and vegetables, and [illegible] cheese made from goats' milk, which are daily s[illegible] Malta. The communication is kept up by 10 or 1[illegible] boats with lattine sails. The *fungus melitensis* grows [illegible] small rock lying off the western end of Gozo; it was [illegible] celebrated as a styptic, and was applied externally to s[illegible] blood. Gozo contains a remarkable ruin called the [illegible] *Tower*, from its being built of enormous stones, w[illegible] cement. A large curious enclosure, with apartments [illegible]tiguous, may be traced, but there is no style of archite[illegible] discoverable in these remains, nor any other indicati[illegible] the æra to which they belong, except that they are [illegible]pean, and certainly of very great antiquity.

Agriculture.—The surface of Malta and Gozo is [illegible]mated at 114 square miles, or 72,960 acres, of which [illegible] two-thirds are cultivated, and the remaining third is rock. Notwithstanding what has been said of the s[illegible] appearance of the island, a spot which nature seem[illegible] condemn to barrenness has been rendered productive [illegible] astonishing degree. It is a vulgar error to suppose th[illegible] soil of Malta has been brought from Sicily. There [illegible] good native earth in the valleys, which has been co[illegible] into productive fields; but a great portion of the la[illegible] been brought to its present state of culture by the [illegible]trious native, who with great labour and expense cuts [illegible] the hard surface of the rock, and frequently finds a q[illegible]tity of earth lying inert in the crevices and inters[illegible]neath. This earth is carefully collected and pla[illegible] layers, seldom more than eighteen inches deep, on l[illegible] loose broken-up rock; and such is the favourable n[illegible] the climate, and the porous quality of the rock itself, [illegible] retains a certain degree of moisture, that the farm[illegible] is not sparing of manure raises two crops a year, w[illegible] ever being obliged to let his land lie fallow. The [illegible] rain in summer is supplied by a heavy dew which f[illegible] night. The produce of Malta is cotton (which is its st[illegible] wheat, barley, pulse, potatoes, barilla, cummin-se[illegible] sulla. This last-named plant, which is what is cal[illegible] French honeysuckle in England, grows to the height [illegible] or five feet, and terminates in a large crimson bloss[illegible] is a substantial and nourishing fodder for animals. W[illegible] and barley are sown in November, and cut in M[illegible] June. There are no oats. As there is no mead[illegible] much barley is cut when green for draught anima[illegible] the straw (which is very fine) is a good substitute f[illegible] The produce of corn is only sufficient for the subsis[illegible] the population for about four months of the year. [illegible] fruits of Malta are generally good and in great [illegible] and the vegetables are excellent. The Malta orang[illegible]perior to all others, and melons, figs, and grapes ar[illegible] particularly fine flavour. No wine is made in Malta.

---

* The Maltese call their antient capital Medina—*the city*.

scrub grows in abundance; some of the carob-trees are a hundred years old, and annually produce a plentiful crop.

Animals.—There are no wild animals in the island, and, from the scarcity of pasture, very few cattle are bred. Meat is principally imported from Barbary. Horses are also imported, but some mules are reared, and the asses of Malta and Gozo have always been celebrated for their strength and beauty; they fetch large sums for exportation. Goats are likewise bred, which are prized for the quantity of milk they give. An animal once peculiar to Malta is the small dog with a long silky coat, mentioned by Pliny, which Buffon calls 'bichon;' but this race of dogs is now extinct. No venomous reptiles are known. As fish forms a large portion of the food of the inhabitants, the markets are well supplied with the common kinds. The dory, rock-cod, white and red mullet, and a species of whiting, commonly called *lupo*, are however generally to be had, and are excellent. The cray-fish, found on the rocks of the island of Gozo, are of enormous size and fine flavour.

Roads and Appearance of the Country.—The roads in Malta and Gozo, generally speaking, are good, and communicate with all parts of each island: those branching off from Valletta have received great attention from the present governor, Sir Henry Bouverie.

The inland modes of transport are by single-horse carts, led horses, mules, or asses of burden. The calesse of Malta is an uncouth-looking vehicle, slung upon a clumsy pair of wheels and shafts, and is made to carry four persons, but always drawn by one horse, by the side of which the driver runs. The glare of the hard naked roads, without hedges and without trees, is injurious to the eyes under a bright sun. The verdure being very partial either in extent or duration, the eye rests upon the innumerable stone dwarf walls, which are built up with the utmost care to prevent the precious earth from being washed away by the rains; and these are only relieved here and there by the fine rich dark tint of the carob-tree, which is always green; and occasionally by the cactus, or Indian fig, which grows in considerable abundance.

Climate.—Although these islands cannot boast of rich landscape, they are blessed with the steadiest climate in Europe. If the shade of trees be wanting, the inhabitants are free from the damp and stagnant air which infects woody countries; and the barrenness of the rock is compensated by the absence of vegetable putrefaction. During the height of summer the heat is sometimes very oppressive; but the houses are spacious and well built of stone, particularly in the capital. Valletta is superior in this respect to any town on the continent. For the greater part of the year the atmosphere is so clear that it gives brilliancy and life to every object. The summit of Mount Ætna may often be distinctly seen at sunrise or sunset, although it is 128 miles distant. The morning and evening sky is also most gorgeous and beautiful. But upon the subject of climate we shall rely upon Dr. Hennen (*Medical Topography of the Mediterranean*), who lived many years in Malta, and whose observations are confirmed by those who have long resided there. Much has been said, he remarks, on the climate of Malta: by some it has been represented as the hottest on earth; by others, as so dry as to be absolutely without fogs or dews; while others again consider it as more variable than the climate of England. Amid this great diversity of opinion however, it is almost universally admitted to be remarkably healthy. On reference to tables kept for the last six years, it appears that the heat indicated by the thermometer within doors has been—maximum 88°, minimum 46°, medium 68°. Every person accustomed to thermometrical observations is aware of the difference between sensible heat and that indicated by instruments. In Malta it is peculiarly striking, and greatly depends on the state of the winds; but it is in the night season that the heat is most oppressive, so much so as to justify the term 'implacable,' which is often applied to it. The sun in summer remains so long above the horizon, and the stone walls absorb such an enormous quantity of heat, that they never have a sufficient time allowed them to get cool; and during the short nights this heat radiates from them so copiously as to render the nights as hot as the days, and much more oppressive to the feelings of those who are accustomed to associate the idea of coolness with darkness. 'I have seen the thermometer (says Dr. Hennen) in a very sheltered part of my house standing constantly during the night the same height to which it had risen in the day; while I marked it with feelings of increased oppression, and this for nearly three successive weeks of August and September, 1822.' No regular sea or land breezes are felt at Malta. As soon as the sun sinks beneath the horizon, the atmosphere becomes close and sultry, and whatever little breeze may have prevailed throughout the day dies away at once. Rain falls with tropical violence in the months of December, January, and part of February. The first indications of rain ordinarily appear about the end of August or the beginning of September. There are then three, four, or more days of heavy showers, with intermediate sunshine. October and the early part of November are delightful; the air is by that time sensibly cooled, and it is occasionally refreshed by showers. This season is denominated St. Martin's, or the little summer. December, January, and February are the rainy winter months, not however without the frequent recurrence of fine days. About March the sky gets settled. An occasional shower may fall in April and May; but during the months of June, July, and August scarcely a cloud is to be seen in the atmosphere. Unlike tropical climates, the rainy season of Malta is not peculiarly unhealthy, which may be in some measure attributed to the fact that the most copious rains fall principally during the night; and so absorbent is the soil in the country, and so well paved and drained are the streets in the city, that the rain is carried off from the surface almost as soon as it falls.

With regard to the winds, the only one which is deleterious is that called the *sirocco* of the Mediterranean; and all winds blowing between the south and east are of this character. In Malta they are most prevalent in the end of August and in all September; or if they blow in other less sultry months, their effects are not so oppressive. Persons who have felt them but slightly on their first arrival have been not the less sensible to them after some time, and feel a languor and disposition to perspire with the slightest exertion. Dr. Benza, speaking of the sirocco as felt in Sicily, gives a correct list of the sensations it causes; a general lassitude or torpor of the muscular system, attended by heaviness and oppression of the nervous system, inducing an inaptitude to any exercise, either corporal or mental; everything is damp and clammy to the touch, particularly one's clothes, which feel as if they had been dipped in water; the appetite is impaired, the thirst increased, the perspiration profuse; in short, one feels as if all the pores (as the common expression is) of one's frame were relaxed and open. All persons of weak constitution suffer considerably under the influence of this wind, and should avoid Malta in the month of September. But the winter of Malta is very delightful. The rain rarely continues for many days together; and although the air is sometimes penetrating, it is very common to enjoy clear weather and a cloudless sky. Frost and snow are unknown. Throughout the spring, northerly and westerly winds refresh the atmosphere; and it is not until the month of July that the inconveniences before described begin to be felt. Malta is eminently fitted for the residence of English invalids during the winter, i.e. from the beginning of October to the end of May. Englishmen may here find English society, reading-rooms, newspapers, &c., and English medical advice. The houses are excellent; living is good and cheap; and the communication with England is speedy and regular. Malta has always been free from earthquakes. It may be remarked that hydrophobia is unknown in Malta; and that horses are never subject to the glanders, or to the disease called grease, so destructive to them in other countries; which may be owing to the dryness of the climate.

Character of the People.—The natives of Malta are a dark-skinned athletic race, and on that account, and from their Arabic dialect, have often been considered of African origin; but we look in vain for the Arab features. They are hardy and robust. The men are about the middle height, erect in stature, well formed, and active. The women are in general below the middle standard, but they are well made and graceful, have regular features and delicate limbs, and many of them are handsome: their complexion is usually dark. Deformity is exceedingly rare, and the general hale appearance of the population is an evidence of the salubrity of the climate. The Maltese marry very early: instances are not uncommon where girls have been mothers at fifteen. The women are very prolific; and where there are so few resources for the employment of families, there must be much poverty and wretchedness;

but the people are industrious, temperate, and frugal, and, being favoured by the climate, their wants are few. The great bulk of the people, who are not employed in field-labour, are stone-cutters. The Maltese are also excellent seamen, and are esteemed such in all the ports of the Mediterranean. In Valletta, since the connection with the English, all articles of household furniture are made in a superior manner, and much furniture is exported to the Levant. Workmen and artisans of all descriptions are numerous and expert in their respective trades. Their carvings in stone and many other works attest an eye and hand capable of great excellence in art. The elegance and beauty of their filagree work in gold and silver are well known. The higher orders enter into all the amusements common to persons of a similar rank in other parts of Europe; but gambling, drunkenness, and intrigue are almost unknown amongst them. They are fond of mixing in English society, and follow its usages: their manners, if not easy, are singularly exempt from vulgarity, and they have a great aptitude in catching those customs which are considered as the marks of good society. The men are generally good men of business, and the women good housewives. The grand-masters, as sovereign princes, granted to many Maltese the titles of marquis, count, or baron, in order to secure in their interests the antient families of the island, and also as a counterpoise to the importance of those who had in a similar manner been raised to nobility by the previous sovereigns. By the law of primogeniture their descendants still form a class of nobility, the property of a few individuals of which amounts to more than 1000*l.* a year, but an income of three or four hundred a year constitutes what is called a rich man. The younger branches sometimes study for one of the liberal professions, the candidates for which are numerous in Malta. All classes are much attached to the British government, and it would be difficult for any other power to seduce them from their allegiance.

Language.—The Italian language was introduced into these islands during the existence of the Sicilian government, and has ever since been in use, chiefly among the upper, but partly also among the middle classes of the inhabitants of the towns, in addition to their native tongue. The Italian has also been generally used in conducting the affairs of government, in legal proceedings generally, ecclesiastical matters, the transaction of commercial business, and for the purposes of education and literature. But up to the present time, the mother-tongue of the people, the Maltese, has continued in use throughout the country and at Gozo, and also among the poorer classes in the towns. It continues to be chiefly used by the upper classes in familiar conversation.

There has been much discussion on the language spoken by the Maltese, and as it is an unwritten language, the subject is one of some difficulty. But Mr. Schlienz, an oriental scholar, and a person who, by a residence of many years in Malta, is entitled to full confidence, has examined the arguments of those who attempt to trace it to the Phœnicians, the Carthaginians, and other antient nations, and comes to the conclusion 'that all its words, with the exception of very few, are purely Arabic, and conform in every respect to the rules, nay even to the anomalies, of the Arabic grammar.' A Maltese finds no difficulty in making himself understood anywhere on the Mediterranean coasts of Africa and Asia, a circumstance which is of no small importance in commercial intercourse, and which might be improved by a systematic cultivation of the Arabic language in Malta, to the great advantage of the Maltese people. The Arabic language was introduced into Malta by the Saracens, who had long had almost exclusive occupation of the island, when it was reduced by Count Roger the Norman.

The English language has made considerable progress in Malta; but it is still a foreign language to most of the natives. Many educated persons speak and write it, and still more read it, with facility. Among the inferior classes in the city, a slight smattering of English, for the purposes of trade, is very common.

Education.—The education of the Maltese has been until lately very limited, although a university, established in the time of the grand-master Pinto, offered to the natives the means of a learned and scientific education, and several erudite works have been written by Maltese authors. Since the Report of the Commissioners of Inquiry in 1838, the means of education have been more widely diffused; the government having, with a view to raise the population from their state of gross ignorance, undertaken the establishment of primary schools throughout the rural districts. Of these there are already twelve open (including Gozo), at which upwards of 1800 children of both sexes receive instruction. In Valletta and the three cities there are three schools, in which 600 children are educated. These schools are conducted upon the Lancasterian plan somewhat modified. The university has been also reorganized upon a more liberal scale, and has about 100 students. The Lyceum or high-school, attached to the university, is increasing in the number of scholars, which amount to 150. Education is therefore advancing in these islands, and will no doubt continue to do so, in proportion as the people become more aware of the advantages which they are likely to derive from it.

Religion.—The religion of the people is the Roman Catholic, to which they are universally and strongly attached, and they are punctually scrupulous in the observances of its ritual. Their religion was secured to them at the surrender of the island to the French republic, and again by the promises of the English generals who took possession of Malta, when the French were driven out of it. This promise has been scrupulously performed, and although the government has been Protestant for thirty-eight years, no religious dissension has been known to disturb the peace of society. The church festivals, which are very numerous, were always celebrated by public processions, which afforded an opportunity to the people of all classes to make holiday; and the women in particular, whom the customs and prejudices of former days kept in strict seclusion, except when they went to church, on these occasions found recreation in the public promenades, for which such festivals served as a pretext. The observances of religion were therefore connected with social life. But in proportion as Protestants and Catholics are becoming more mixed together in the forms of modern society, these festivals and ceremonies are less thought of, and in fact are gradually diminishing in importance. Both parties observe a moderation and deference for each other's opinions in religious matters; and Malta thus exhibits a striking and almost solitary instance of a highly religious people, ruled by a government of a different creed, by whose tolerance all live in the greatest harmony.

The Roman Catholic clergy are very numerous, amounting, between regulars and seculars, to about one thousand, some of whom are eminent for learning. The landed property of the church is about one-fourth of the rental of the island, out of which the bishop enjoys an income limited to 3000*l.* a year.

The Protestant places of worship are few and unassuming. The governor has his chapel in the palace of government; the naval departments have theirs in a building near the naval arsenal; there is a Sunday-evening service in the house of the Church Missionary Society; and the Wesleyan mission has a chapel, which has the external appearance of a private house. The number of Protestants in Malta is something under a thousand, not including the troops, whose religious service is performed by the military chaplain in their respective barracks. They have long desired to see a church erected for their use; this wish will speedily be realised, her majesty the queen-dowager having munificently signified her intention, on her late visit to Malta, to erect a church at her sole expense for the public worship of the church of England. The site for this building in the city of Valletta was cleared in January, 1839.

Population.—The increase of the population of Malta, after it came into the possession of the Knights of St. John, was very rapid. It seems to have been the policy of that government to stimulate it by all the means in its power. Property is still held by the present government, which is charged with the payment of annual sums, in dowries for the encouragement of marriages among the poorer people.

In 1530, when the Order took possession of the islands, the population amounted to	17,000
In 1632, according to Boisgelin . . .	51,750
In 1791, according to St. Priest . .	90,000
In 1798, according to Boisgelin . . .	114,000
In 1803, according to Colquhoun, 'Wealth of the British Empire' . .	94,000
In 1813, before the breaking out of the plague	102,000
In 1828, according to a census taken in that year	119,194
In 1838, according to the last census .	120,989

	61,129	59,830
		61,129
	Total	120,959

Government.—Malta is a crown colony, and the local government is conducted by a governor, who in legislative matters is assisted by a council of six persons nominated by the crown. The principal administrative departments are the chief secretary's office, the quarantine department, the custom-house, the land revenue department, and the audit office. The courts of justice are numerous, and the procedure intricate and costly; the law administered by them is likewise in want of a thorough revision. The public revenue of the island amounts to about 100,000*l.* a year, of which about 47,000*l.* arises from custom duties (chiefly levied on grain and pulse) and quarantine dues; about 33,000*l.* from the rents of government lands and houses; and the remainder from several small duties. Out of this sum are defrayed not only the salaries of the regular government officers, but also the expenses of maintaining the roads, streets, and public buildings, and the cost of the university, elementary schools, and charitable institutions. Some reduction in the public burdens may be expected to be made in consequence of the recommendations of the recent commission of inquiry.

History of Malta.—The earliest notice of the Maltese Islands is in Diodorus of Sicily (v. 12). 'There are,' he says, 'over against that part of Sicily which lies to the south three islands at a distance in the sea, each of which has a town and safe ports for ships overtaken by tempests. The first, called Melite, is about 800 stadia from Syracuse, and has several excellent ports. The inhabitants are very rich, inasmuch as they exercise many trades, and in particular they manufacture cloths remarkable for their softness and fineness. Their houses are large and splendidly ornamented with projections and stucco (γείσοις καὶ κονιάμασι). The island is a colony of the Phœnicians, who, trading to the western ocean, used it as a place of refuge, because it has excellent ports and lies in the midst of the sea. Next to this island is another named Gaulus (Gozo), with convenient harbours, which is also a colony of Phœnicians.'

Malta is said to have been subsequently occupied by the Greeks; but however this may be, the Carthaginians obtained entire possession of it, B.C. 402. In B.C. 242 the Carthaginians were compelled to cede it to the Romans, who erected the island into a municipium. It appears that the temple of Juno was rich enough to be an object of plunder to the rapacious Verres, when he was prætor of Sicily. (Cicero *In Verrem*, iv. 46.) The linen cloth of Malta was considered an article of luxury at Rome.

The Vandals and the Goths, who had taken possession of Malta, were expelled by Belisarius, A.D. 533. About A.D. 870 the Arabs took possession of the island; and though it was recovered and held by the Eastern empire for about thirty-four years, it was retaken by the Arabs, and the Greek inhabitants were exterminated. In 1120 Count Roger, the Norman conqueror of Sicily, took possession of Malta, and expelled the Arabs.

Malta was thus attached to the island of Sicily, and it became subject to the different dynasties which successively governed that island, viz. the house of Hohenstaufen (A.D. 1189), Charles of Anjou (A.D. 1265), and the house of Aragon (A.D. 1282). During this period an officer of the Sicilian crown presided over the government of Malta, and the Sicilian laws and institutions were extended to the island. One of these institutions was a municipal council or body, similar to the municipal councils of Sicily, which originated in the reign of Frederick II. of the house of Hohenstaufen. This municipal council appears from its archives, which are still preserved at Malta, to have exercised considerable administrative and even legislative powers; though its formation and constitution are quite obscure.

In 1516 Sicily, with the Maltese islands, passed to the emperor Charles V., as heir to the crown of Aragon. On the 4th March, 1530, Charles granted to the grand-master and religious fraternity of St. John, who had recently been expelled from Rhodes by the Turks, the ownership of all the castles, fortresses, and isles of Tripoli, Malta, and Gozo, with complete jurisdiction. The sovereignty of Malta was by this grant in effect surrendered to the Knights, though the form of tenure from the crown of Sicily was maintained by the reservation of the annual payment of a falcon by the Knights to the king of Sicily or his viceroy. At the time of the cession Malta contained only about 12,000 and Gozo about 5000 inhabitants, who were in a miserable condition. Malta was almost a barren rock, and the cultivation of the land had been nearly abandoned, owing to the wretched system of administration and the frequent predatory visits to which the people were exposed.

Under the Order Malta soon began to recover from its state of destitution. The first object was to protect the island against the incursions of its piratical enemies; and with this view the Knights commenced those works which remain to this day as a monument of their perseverance and military power. On the 18th May, 1565, the Turks under Mustapha Pacha, to the number of 30,000 choice troops, landed on the island of Malta, where they encountered a desperate resistance from the Knights. Finally, the Turks were compelled to quit the island, with the loss, it is said, of 25,000 men; the loss on the other side was computed at about 5000. Upon the death of Sultan Solyman in 1566, shortly after the defeat of his troops, the grand-master La Vallette, who had successfully defended Malta against this formidable invasion, determined on the founding of a new city, in a favourable position for the protection of the island, and as a residence of the convent of the Order. He laid the first stone of the city of Valletta, which bears the name of its founder, on the 28th of March, 1566. The Knights, now secure in their possession of Malta, continued to cruise against the Ottomans, whom they greatly annoyed. But the discipline of the Order relaxed as the objects of their original institution gradually became of secondary importance; and Malta, which was safe against all attack, was a place of luxury and pleasure rather than of austerity.

The history of the island, between this time and its surrender to Bonaparte, requires no particular notice in this brief sketch. The outbreak of the French revolution was an event calculated to shake the declining power of an institution like that of the Knights of Malta, and the behaviour of the Order towards the new republic of France, their supposed partialities, their vessels, and their agent in Malta, certainly contributed to the downfal of the Order. The immediate surrender of the island however was perhaps owing in part to the pusillanimity of the Grand-master, as it certainly was in a great degree to the treachery of the French Knights, who, foreseeing the decline of the Order and the probability of Malta being placed under Russian influence, preferred its surrender to France, whether that country should be a monarchy or a republic.

On the 9th June, 1798, a French expedition, under the command of Admiral Brueys, consisting of 13 ships of the line, 16 frigates, and about 400 transports, having 40,000 men on board, arrived off the island. The French Knights had already been prepared for what was to take place: the Grand-master Ferdinand Hompesch, who had been elected in July, 1797, a weak and credulous man, took no means to deprive the French Knights of the principal military commands. Most of the towers along the coast fell under their orders by a rule of service. Although much time was lost in concerting measures of defence, nothing was done: in fact muskets were delivered to the troops unexamined; the ammunition was damaged and unsound; troops were despatched to the coast without provisions; conflicting and impracticable orders were issued, and other similar apparent accidents happened. Baron Azopardi, in his 'Journal of the Taking of Malta,' states that the inhabitants ran in thousands to arms, but the military chiefs were satisfied with a semblance of preparation, and deluded the people with assurances of security. General Bonaparte, who was on board the ship of the line Orient, lost no time in making a demand in writing that the whole fleet should be allowed to enter the ports of Malta to water, to which an answer was returned, with expressions of regret, that only two, or at most four ships, could be allowed to enter the port at a time. 'The Grand-master refuses us water!' said Bonaparte; 'to-morrow at sunrise the army will disembark upon the coasts of the island wherever a landing can be effected:' and these words were inserted in the order of the day.

Accordingly, the next morning a body of French troops disembarked in St. George's Bay to the north-westward of Valletta, where one gun was fired from the tower for form's sake, and the batteries of St. Elmo and Fort Tigné opened a fire, which was ineffective from their position. Another corps landed in St. Paul's Bay unmolested, and a third in the harbour of Marsascirocco, to the south-east. Before night the French were in possession of the whole country, with the exception of five villages, or casals, without any opposition on the part of the knights who commanded the several posts; and the unsupported attempts of the Maltese battalions of Nasciar, Musta, Gargur, and Birchircara to defend their homes, only afforded to troops like the French a pretext for bloodshed and plunder. In the meantime the city of Valletta was in a state of tumult and despair. The Grand master, in a state of the greatest perplexity, was surrounded by various advisers, but wanted firmness to decide. At length, when it was reported to him that some French knights had been killed, and others wounded, by the Maltese soldiers, he felt his critical situation, and determined to solicit a suspension of arms. Two messengers were immediately sent on board the Orient to announce the readiness of the Grand-master to come to terms; they were bearers of a letter from the Danish consul to the French general, interceding for his favour, and another from the Grand-master himself to the commander Dolomieu, a knight of the Order, who had openly attached himself to the French, and was on board the Orient, soliciting his good offices. In the afternoon General Junot and others brought an answer to the palace, allowing the Grand-master twenty-four hours to send his delegates to conclude the capitulation.

Distrusting their government, the inhabitants claimed to take part in the deliberations; and to two knights and four influential citizens were confided the conditions upon which the fortress was to be surrendered. On the 12th of July the capitulation was signed on board the Orient by Bonaparte himself and these delegates. By its stipulations the Order of St. John of Jerusalem renounced, in favour of the French republic, the sovereignty of Malta, Gozo, and Cumino; the French republic pledged itself to use its influence with the congress of Rastadt to procure for the Grand-master during his life a principality equivalent, and in the meanwhile he was to be allowed a pension of 300,000 francs; the French knights were to be allowed to return to their country; to the French knights then in Malta pensions of 700 francs were to be paid, and 1000 francs to those of sixty years and upwards; it engaged to intercede with the Cisalpine, Ligurian, Roman, and Helvetic republics, to obtain similar pensions for the knights of those countries, and also with the other European powers, to secure to the knights of each the property of the Order. The knights were moreover permitted to retain their private property in Malta and Gozo; and the inhabitants were to continue in the free exercise of the Roman Catholic religion; to be secure in their property and privileges, and no extraordinary contribution was to be imposed upon them. This capitulation was more favourable than could have been expected. Hompesch was not asked to ratify its conditions.

In the afternoon of the same day the French ships of war and transports anchored in the ports of Valletta and Marsascirocco, and 15,000 troops took possession of Valletta, the three cities on the other side of the harbour, and their outworks. The French general had no sooner entered the gates than he eagerly made a personal inspection of the fortifications. 'It is well, General,' said Caffarelli, one of the officers of his suite, as he accompanied him, 'it is well that some one was within to open the gates for us. We should have had some difficulty in entering had the place been altogether empty.'

The French found in the port two line-of-battle ships, one frigate, and three galleys, besides two galliots, and some guard boats; and of ordnance 1500 pieces of artillery (about 600 of which were mounted on the works), together with 35,000 stand of small arms, 12,000 barrels of powder, and an immense number of shot and shell.

The Order of Malta was now extinct. Hompesch embarked privately in a merchant-ship in the night of the 17th of June, accompanied by twelve knights. On his arrival at Trieste he resigned his office of Grand-master of the Order of St. John. General Bonaparte sailed with the French expedition two days afterwards for Egypt, and General Vaubois was left with 4000 men to take care of Malta.*

As soon as the French were masters of Malta they established laws borrowed from the recent legislation of France, and formed an entirely new government and municipality, administered by a commission. Liberty and equality were proclaimed, titles and ranks were abolished; it was decreed under a heavy fine that the sons of the richest families should be sent to France for education in the new principles, at their own expense; all the establishments were reorganised, and the remaining knights, with few exceptions, were obliged to leave the place. The riches of the church of St. John, and of the other churches, and of the *auberges* of the *langues*, the plate of the hospitals, and of the Grand-master's palace, were melted down to be sent to France. (Baron Azopardi; and *Pièces Diverses rélatives aux Opérations Militaires et Politiques du Général Bonaparte*, Paris, an viii.)

Three months of subjection to such arbitrary measures and violent changes were sufficient to convince the Maltese that they had exchanged an enfeebled despotism for a harsh yoke. A total disregard of the articles of the capitulation was daily manifested, and even some alterations of the civil law which affected the tenure of property filled up the measure of hatred to their new rulers.

Besides the churches which had been pillaged in Valletta, those at Città Notabile, including the cathedral, did not escape plunder; but there still remained some rich silk damask in the churches and convents of the antient city. On the 2nd of September, 1798 (after the news of the battle of Aboukir had reached Malta), some persons being sent to Città Notabile to take down these decorations, the inhabitants assembled to prevent it. The French commandant of the small garrison of sixty-five men, in an endeavour to disperse them, imprudently drew his sword. In a moment he was attacked, and the people being joined by others from the neighbouring casals, the irritation increased, and the officer and the whole of the detachment were massacred, and their bodies burned. This was the signal for a general revolt. In twenty-four hours the insurrection spread throughout both islands. On the 3rd, General Vaubois, having learned what had taken place, attempted to send a detachment of 200 men to keep possession of Città Notabile, but they were beaten back by the Maltese peasantry. On the same day the people of the villages near the fortifications of Cottonera entered the town of Burmola, and, being joined by the inhabitants, attacked the French guard and carried off the standard of the republic. Others in the meantime took possession of a magazine, and after a sharp contest bore away to the country eighty barrels of gunpowder.

The energy and daring which the Maltese thus early showed in their patriotic warfare surprised General Vaubois, who had been accustomed to consider them as wretched peasants. From this moment the gates of Valletta and the three cities were closed, and the garrison was kept in a close state of blockade for two years.

During this long period the Maltese gave proof of a patriotic ardour and long-suffering which few people would have equalled. Unanimous in their object, all their measures were taken with prudence and order. They collected arms and established a system which gave method to all their operations, and their levy of men was divided into bodies or battalions, and distributed in the towers on the coast and throughout the country, with almost as much order as regular troops.

The attempts made by the French general at conciliation were not listened to; his messengers were never allowed to go back; and he soon found to his surprise that the people had firmness enough to persevere in the enterprise they had undertaken, nothwithstanding they were at present single-handed.

---

* The only detail we have of these transactions in English is by the Chevalier de Boisgelin ('Antient and Modern Malta,' London, 1805), who was a French knight of Malta; and he writes in the true spirit of an adherent to his Order. The present account of the surrender to the French, and what follows on the subsequent blockade by the British and Maltese, was written on the spot, and is confirmed or corrected by persons who were contemporary with the events.

With more than 4000 well-disciplined troops under his command (the soldiers and the crews of the vessels which escaped from Aboukir having been incorporated with them), he was unable to make a sortie in sufficient force to overawe his enemies; for the people of Valletta, encouraged by the movement of their countrymen, and borne down by forced contributions and the privations inseparable from a state of siege, were not to be left unwatched within the walls. The Maltese now made a warm appeal to the king of Sicily as their sovereign. They sought assistance from the British fleet, and sent out boats in all directions, one of which fell in with a vessel that communicated with Lord Nelson on his return from the battle of Aboukir; he sent the Portuguese squadron to their aid, his own ships being much disabled, and promised soon to follow. In fact on the 18th of September four Portuguese ships of the line and two frigates came off the island and commenced the blockade of Valletta, and supplied the Maltese with some arms and artillery. On the 24th of October Lord Nelson himself appeared with fourteen ships of war, and summoned the French to surrender, offering to send them all to France, and not consider them as prisoners of war; to which General Vaubois returned a laconic refusal. The English admiral's force not being in a state to keep the sea, he was obliged to go to refit, and he left the Portuguese admiral to maintain the blockade. So noble and encouraging was his reception of the Maltese deputies, that Nelson's name served as a word to animate their efforts throughout the rest of their long struggle.

All sorts of provisions still continued very scarce, and many of the inhabitants were reduced to the greatest misery. The king of Sicily, who had already supplied them with powder and shot, now permitted them to receive corn from his granaries upon credit. Yet their great support was the reliance they had on the presence of the British navy. Captain Alexander John Ball, who commanded the squadron afterwards appointed by Lord Nelson to continue the blockade of Valletta, was likewise ordered to supply as far as practicable the wants of the Maltese. This service could not have been entrusted to better hands. Captain Ball was a man whose dignified deportment and mild and gentle manners were such as to acquire respect and esteem; his sympathy and consideration too for the Maltese was a sentiment of the heart, not a cold act of duty.

In the beginning of 1799 the Maltese elected him their chief and the president of their congress, which was immediately organised, and consisted of the bishop's delegate in ecclesiastical matters, a judge, and twenty-two representatives elected by the casals. The affairs, civil and military, of the Maltese now began to take the form of a regular administration under the direction of Captain Ball. The congress authorised a public loan to be opened, and the landed property of the church and of the late Order to be let for the purpose of paying the expenses of the war. The customs were also regulated, and the bays of St. Paul and Marsascirocco were made the authorised ports for trade. In April Captain Ball received, through the British minister at the court of Naples, an order from the king of the Two Sicilies to assume the command of Malta for his majesty, and the Neapolitan flag was now raised upon the Maltese batteries in conjunction with the English. A sum of money (about 2600*l.*) was about this time received for the first time, and was afterwards followed by others, which although supplied in the name of the king of Naples, were really furnished from the English subsidies. Very soon after this Lord Nelson authorised Captain Ball to assure the islanders that Malta would be protected by England, Russia, and Portugal until a general peace. All matters therefore seemed to be as well regulated as circumstances would admit, and the most ardent hopes were entertained that an end might speedily be put to the sufferings of the Maltese by the surrender of the French garrison, which was now strictly watched by land as well as by sea. But they had still much to contend against, and among other calamities disease, brought on by long suffering, and famine carried off many of the poorest classes, for whose relief no charitable fund existed; and it is stated that during the two years not less than 20,000 persons died of misery and famine. The expelled knights of the Order were not indifferent to what was going on in Malta; the bailiff de Neveu and some others attempted to land, offering their services to assist in recovering the island from the French, but they were rejected with indignity.

At the commencement of the siege the quantity of corn in the granaries of Valletta and the three cities was 20,000 quarters, which it was calculated would subsist the inhabitants and the garrison about 16 or 17 months. The city was so closely blockaded by sea, there seldom being less than three or four ships of the line, and as many smaller vessels cruising off the port, that only 17 small vessels with supplies, besides the frigate *Boudeuse*, got into the port during the first twelve months; and the situation of the besieged, before scarcely four months had elapsed, was such, that Ransijat, treasurer of the Order, who has given us a very detailed journal of the occurrences within the city, says that the countenances of many bore marks of the cruel privations to which they were subjected. Famine stared them in the face, and many who were at first unwilling to leave their homes and properties, were afterwards glad to obtain the permission of General Vaubois to escape from the horrors of a siege and the insatiability of military rapacity. The population, which at the beginning of the blockade had been estimated at upwards of 40,000, by this means was reduced in September, 1799, to 14,000, and consequently the corn in the magazines was sufficient to last much longer than was at first calculated; yet in the subsequent month, General Vaubois managed to send despatches to France to inform his government that his supplies would not hold out beyond the following May. The inhabitants were not a little cast down by this anticipation, particularly as in July the garrison had been put upon half-pay, and the salaries of the authorities were suspended from the scarcity of money in the treasury. Still, trying as was their situation, the buoyant spirit of the French soldiers never deserted them; they made gardens in the fortifications, and raised fruit and vegetables to ameliorate their situation. At this time a pound of fresh pork sold for 6*s.*, salt meat 3*s.* 10*d.*, the commonest fish 5*s.* 5*d.*, a fowl 20*s.*, a pigeon 12*s.*, a pound of sugar 18*s.* 8*d.*, coffee 21*s.* 8*d.*, a good fat rat 1*s.* 7*d.*

The Maltese at first raised but few batteries, and those inconsiderable ones. When however they were joined by the English and Portuguese, who furnished them with mortars and cannon and a great quantity of ammunition, they erected others of much greater importance, in situations which kept the French garrison in constant apprehension, as we learn from Ransijat's 'Journal.' They were assisted likewise by the marines landed from the blockading squadron. In December, 1799, Brigadier-General Graham (now Lord Lynedoch), arrived with the 30th and 89th British regiments and some artillerymen; these were joined by the 35th and 48th regiments under Major-General Pigot, who took the command in June, 1800. Two Sicilian regiments also formed part of the besieging forces; and in official orders they were styled the allied troops at the blockade of Valletta.

In the beginning of September, the French troops being reduced to the last extremity, and the rigour of the blockade by sea and land depriving them of every hope of relief, General Vaubois made proposals to surrender the place into the hands of the English troops. This act was signed and concluded on the 5th of September, 1800, by General Vaubois and Admiral Villeneuve on the part of the French, and by General Pigot and Commodore Martin on the part of the English; and its principal conditions were, that the French troops should march out with the honours of war, as far as the sea-shore, where they should ground their arms, and then be embarked for Marseilles as prisoners of war, until exchanged. The next day four regiments of British troops took possession of the forts and batteries of Valletta, amidst the acclamations of the people; they hoisted the English ensign at St. Elmo, and the British squadron entered the port. Two days afterwards, everything being ready, the French troops sailed for France in English transports; and thus, after two years and two days, ended this protracted and memorable blockade.

At the peace of Amiens in 1802, the question of Malta was one of difficult arrangement. It was however eventually settled between Great Britain and the French republic, that the island should be restored to the Knights of St. John, and be an independent state as formerly, but that there should be neither an English nor a French langue, and that a Maltese langue should be established, which should enjoy all the influence and privileges of the other langues.

In strict conformity with this treaty, Malta was to have been evacuated by the British troops in three months after its ratification. But before the lapse of that period, circumstances had arisen which not only retarded the restoration of the island to the Knights of St. John, but rendered that measure inconsistent with the interests of Great Britain, and the security of her Indian possessions. Thus the treaty of Amiens remained unexecuted, and Malta remained in the hands of the English. On the 18th of the same month George III. issued a declaration of the motives which obliged him again to take up arms.

During the hostilities which followed, Malta was retained in military possession by Great Britain, without any formal declaration as to who was to be its future master. It became the head-quarters of the English army in the Mediterranean, and the rendezvous of the British fleet, which found there every advantage from a central situation, and the convenience the ports of the island afforded for fitting out and keeping in an effective state the squadrons which held the dominion of the seas from Gibraltar to the Dardanelles. It became the emporium of that commerce which was shut out from all the ports of the Continent by the operation of the Berlin and Milan decrees, and it was the only place in the Mediterranean whither the rich prizes taken from the enemy were carried for adjudication. This was a time of great prosperity to Malta; it however received a sudden interruption from the plague which broke out in 1813. From April of that year, when Valletta was so active in traffic and bustle, to September, 1814, there died 4668 persons in both islands. During the greater part of this period the capital was deserted, except by the mournful dead-cart; the grass grew in the streets, and everybody was shut up as in a prison.

On the 30th of May, 1814, a definitive treaty of peace, concluded at Paris between France and the allied powers, fixed definitively the lot of Malta, by a formal recognition of her union with Great Britain, with the concurrence of the king of Sicily, whose predecessors had for three centuries only exercised suzerainty over the island. Thus the Maltese people at length obtained the fulfilment of their wishes, and became subjects of a sovereign of their own choice. It is only under a great maritime power that they can be secure from aggression.

But the island did not recover its late excess of prosperity. The peace, which carried blessings to all the nations of Europe, opened the ports of the Continent to English commerce, which naturally neglected Malta and went thither direct. Malta besides was obliged to suffer a sort of penance inflicted upon her by the ports of France and Italy, whose health establishments kept her in quarantine for 12 years after the cessation of the plague. It was not until June, 1826, that she was admitted to communicate freely with these commercal states; and by this time her principal commercial establishments were broken up. The expenditure of a garrison and a small squadron, and a limited trade with Barbary and the Levant, were her only resources, and formed no approach to the florid state of prosperity she enjoyed soon after her first connection with Great Britain.

In the mean time her already excessive population was upon the increase, and her expenditure undiminished, and in 1832 the people began to petition his late majesty, William IV., for a consideration of their depressed condition, alleging certain grievances, which were then but cursorily considered or ineffectually remedied. In June, 1836, they made a more forcible appeal to the British government through the House of Commons, by a petition signed by 2388 Maltese, which was presented in that house by Mr. Ewart, on the 7th of June, 1836. The Maltese in this appeal prayed for a municipal body, a reform of the law, a moderate liberty of the press, an improvement of the system of education and elementary instruction, an independent board of health, a free port, a relief from the heavy excise duty on wine, a participation in the emoluments of office, a relief from the heavy duty on grain, and a popular council for the election of representatives to make known their wants and grievances. Commissioners of Inquiry were sent out in September, 1836, to examine and report upon the grievances set forth, and from their labours the most useful reforms are anticipated. Some indeed are already in operation: such as a complete freedom of the ports of Malta for all foreign merchandise, the duties remaining only on articles of consumption; the reform of the government departments, and the distribution of the higher offices more fairly among the Maltese, which were formerly held almost exclusively by Englishmen through patronage; a reconstruction of the university, and the introduction of elementary education amongst the lower orders; and though last, not least, the full liberty of printing and publishing, under laws to be enacted, by which the people will always be enabled to make known their complaints to the British government and the British people.

What promises however to be of the greatest benefit to Malta is the development of steam navigation in the Mediterranean within these few years past, not only from the passage of vessels from the coasts of France and Italy to the Levant, which all meet at Malta as the most advantageous point of rendezvous, and to provide themselves with coals, but from the increasing importance of the communication between England and India through the Mediterranean. Travellers of all nations are to be seen in the streets of Valletta, and there, where a few years ago every face was familiar, one now walks amongst strangers as in continental cities. This affluence of persons has led to the establishment of hotels of the best sort; and the improvements in the lazaret have stamped Malta as the most important quarantine station in the Mediterranean, and that which is now most resorted to by travellers of all countries.

MALTA, KNIGHTS OF, a celebrated military and religious order, known also by the names of Knights of St. John of Jerusalem, Knights Hospitallers, and Knights of Rhodes. The institution of the Order originated in an hospice which was founded at Jerusalem, by permission of the caliphs of Egypt, about the middle of the eleventh century, for receiving the pilgrims from Europe who visited the holy sepulchre. The hospice was annexed to a chapel dedicated to St. John the Almoner, and was at first kept by Benedictine monks. When Palestine was conquered by the Seljuk Turks, in 1065, who drove away the Arabian and Egyptian Saracens, the Christians found these new masters much worse than the former, and the hospice of St. John was plundered. Some time after, a Frenchman named Gérard, a pilgrim to the holy city, undertook the management of the hospice; and when the crusaders under Godefroy de Bouillon took Jerusalem in 1099, they found Gérard, who had been kept in prison by the Mussulmans during the siege as a suspected person. Gérard resumed his duties in the hospice, and several of the crusaders, through pious fervour, determined to join him and to devote the rest of their lives to the service of the poor pilgrims. Among the knights who took this determination were Raymond Dupuy and Dudon de Compt, both from Dauphiné, and Conon de Montaigne, from Auvergne. Godefroy de Bouillon made a donation of his own lordship of Montboire in Brabant to the hospice of St. John, and several other princes followed his example. The hospice thus became possessed of lands in almost every part of Europe, as well as in Palestine. The dress assumed by the new Hospitallers was black, with a white cross, having eight points or arms on the left breast. Pope Paschal II. sanctioned the new institution, the members of which bound themselves by solemn vows of chastity, individual poverty, and obedience, to which was afterwards added that of being always ready 'to fight against Mussulmans and all others who forsake the true religion.' Vertot, at the end of his 'History,' gives all the laws and regulations of the Order: 'Anciens et nouveaux Statuts de l'Ordre de St. Jean de Jerusalem.' The pope exempted them from paying tithes, and gave them the right of electing their own superior, who was styled grand-master. They were independent of every other ecclesiastical or lay jurisdiction. A splendid church was raised by Gérard near the old hospice, and dedicated to John the Baptist, with extensive buildings for the Hospitallers as well as the pilgrims, who were there entertained at free cost. Gérard and his successors established, in various maritime towns of Europe, hospices in imitation of that of Jerusalem, which served as resting-places for the pilgrims, who were there provided with the means of embarking for Palestine. These houses were called commanderies. Such were those of Messina, Tarentum, Seville in Spain, and St. Gilles in Provence.

Gérard dying in 1118, the Hospitallers elected as his successor brother Raymond Dupuy, who drew up a body of statutes or regulations of discipline for the Order. He first added to the duties of charity and hospitality that of taking up arms for the protection of the holy sanctuary. He divided the brethren into three classes, the military, the priests and chaplains, and the 'serving brothers,' who were neither soldiers nor priests. As the Order increased rapidly in numbers, the members were classed into seven nations, called 'languages,' namely, Provence, Auvergne, France, Italy, Aragon, Germany, and England. For nearly two centuries the Hospitallers, together with the Templars, were the firmest support of the Christians in the East; and when Acre, the last bulwark of Christendom, was taken by the Mussulmans in 1291, the remains of the Order withdrew to Cyprus, where the town of Limisso was assigned to the Hospitallers as their residence.

In the year 1310 the Hospitallers, having lost all hope of recovering Palestine, equipped a fleet, and, being joined by crusaders from Italy, landed, under their grand-master Foulques de Villaret, on the island of Rhodes, which was then possessed by Greek and Saracen pirates. The Hospitallers defeated the pirates, and took formal possession of Rhodes, as well as of Cos and other neighbouring islands. [RHODES.] From that time they became known by the name of Knights of Rhodes. The knights strongly fortified the town of Rhodes, from which they carried on by sea a deadly warfare against the Mussulmans, and especially against the Ottoman Turks, who about that time were establishing their power all over Asia Minor. The history of the Knights of Rhodes, during the fourteenth and fifteenth centuries, is closely connected with that of the Ottomans. Some of the Turkish sultans, among others Amurath, or Mourad II., were glad to purchase a temporary peace from the knights. Mahomed II., son of Murad, having taken Constantinople, sent a fleet with an army to conquer Rhodes in 1480; but the Turks were repulsed by the knights, under their grand-master Pierre d'Aubusson. In 1522, Sultan Solyman the Great sent another large armament against Rhodes, and he himself repaired thither to direct the siege. Villiers de l'Isle Adam, who was the grand-master of the Order, defended the town with the utmost bravery; but there was a traitor among them, one D'Amaral, a Portuguese knight, who, through jealousy and disappointment at not being made grand-master, kept a correspondence with Solyman, and informed him of the state of the garrison and the weak points of the fortifications. D'Amaral was discovered and executed; but in December of that year the grand-master, having exhausted all his means of resistance, capitulated. Solyman behaved honourably: he allowed the knights, and all the inhabitants who chose to leave Rhodes, twelve days to embark with their moveables. Having expressed a wish to see the grand-master, he gave him words of consolation, and, touched by his venerable appearance, said to his vizier, that 'He could not help being grieved at driving that Christian in his old age out of his house.' On the 1st of January, 1523, the grand-master and the surviving knights left Rhodes and took refuge in Italy.

In 1530 Charles V. gave to the Order the islands of Malta and Gozo. [MALTA.]

After the surrender of Malta to the French, in 1798, the Order as a sovereign body became extinct, and its domains in various parts of Europe were confiscated. It still however exists as a religious order, a phantom of its former greatness. Ferrara in the Papal State is at present the residence of the grand-master and a few knights of the order of St. John of Jerusalem, who subsist upon some scanty remnant of their antient splendid revenues. Circumstances have so much altered in Europe, the Levant, and Africa, that the Knights of Malta as a sovereign military order would no longer be in harmony with the actual state of civilization. The objects of their institution have long ceased to exist. They were however for some centuries, together with Venice, the firmest bulwarks of Italy and western Europe against the barbarian power of the Ottomans.

(Vertot, *Histoire des Chevaliers Hospitaliers de St. Jean de Jérusalem.*)

MALTHA, a bituminous mineral, of which such different accounts are given by various authors, that it is impossible to determine to what substance the name properly belongs. In proof of the justness of this conclusion, we may merely observe that according to Phillips (*Mineralogy*, p. 368), it is blackish-brown; while according to Dr. Thomson (*Inorganic Chemistry*, vol. ii., p. 369), it is white.

MALTHUS. [POPULATION.]

MALTON. [YORKSHIRE.]

MALU'RUS. [SYLVIADÆ.]

MALVA SYLVESTRIS (Wild Mallow), an indigenous, perennial, herbaceous plant, of very frequent occurrence, possessed in every part of mucilaginous properties, and which may be employed for the same ends as other demulcent herbs. The flowers only are officinal in Britain: when fresh, they are violet-coloured, but by drying become blue, and also lose a large quantity of their watery constituents, for 100 parts of recent flowers dry into 11. They have no odour, but a mucilaginous herbaceous taste. They yield their colouring principle both to water and alcohol. The alcoholic tincture furnishes one of the most delicate of re-agents for testing the presence of acids or alkalies. The compound decoction of the London Pharmacopœia is not a proper form of exhibition, an infusion with cold water being preferable. [DECOCTIONS; INFUSIONS.]

MALVA'CEÆ are a large natural order of exogenous plants, the distinguishing marks of which are polypetalous flowers, monadelphous stamens, unilocular anthers, and a valvate calyx. They also have alternate leaves, the hairiness of which, if present, is usually stellate; and conspicuous stipules. A large proportion of the order consists of herbaceous or annual plants, inhabiting all the milder parts of the world, but much the most plentiful in hot countries, where alone a comparatively small number of species become trees. In many cases they are remarkable for the large size and beautiful colours of their flowers, which are however fugitive, expanding for a single day only; the great number of them and the regularity of their succession during the flowering season make this of little importance. Among the very numerous species several are of essential service to man. As emollients they are well known in medical practice, the Marsh-mallow (Althæa officinalis) being one of the most useful among this kind of remedial substances, and a large proportion of the whole order being capable of supplying its place. The hairy covering of the seeds of the various species of Gossypium forms the raw cotton so important to our manufacturers. Malva tricuspidata is used by the negroes in the West Indies as a substitute for soap. The seeds of Hibiscus abelmoschus are warm and musky, and are employed in perfumery as a substitute for musk; those of Hibiscus esculentus form the ochra, so much used in hot countries as a mucilaginous in-

Gossypium tricuspidatum.

1, a section of a corolla, with adhering monadelphous stamens.

gredient in soups. A few species are acid, especially Hibiscus sabdariffa. Finally the tenacious fibres procured from the inner bark of many kinds of Malvaceous plants form a good description of cordage. Hibiscus elatus and tiliaceus, and several kinds of Sida, are principally used for this purpose.

The only modern systematical account of the genera and species of the order is to be found in the first volume of De Candolle's 'Prodromus;' but the genera have been since constructed upon principles so much more precise, and the number of species has been so very considerably increased, that this enumeration is of little use at present. There is a good account of Indian species in Wight and Arnott's 'Prodromus Floræ Peninsulæ Indiæ Orientalis;' of Brazilian species in Auguste de St. Hilaire's 'Flora Braziliæ Meridionalis;' and of Mexican kinds many are described in the various volumes of the 'Linnæa.' A few African species are also to be found in Guillemin and Perrottet's 'Flora Senegambiæ,' vol. i.

MALVERN, MALVERN HILLS. [Worcestershire.]

MALWA. [Hindustan, p. 212.]

MAMELUKES, or MEMLOOKS, a name derived from an Arabic word signifying slaves, was that of a military body which for a long time ruled Egypt. The Memlooks were first instituted in the early part of the thirteenth century by Malek Salech, grandson of Safadeen, which Safadeen was the brother of the famous Salah Edeen, the Koord, the founder of the Eyoob dynasty of the sultans of Egypt, which succeeded the Fatemides. Malek Salech purchased many thousands of slaves, with which the markets of Asia were then glutted in consequence of the devastating wars of Gengis Khan. He chose chiefly young natives of the Caucasian regions, whom he trained to military exercises, and embodied into a corps of 12,000 men called Memlooks. This corps, by its discipline and distinct organization, became formidable to its masters. In 1254 the Memlooks revolted and killed Tooran Shah, the last prince of the Eyoobite dynasty, and raised to the throne of Egypt El Moez Turkoman Memlook. El Moez was murdered in 1261 by another Memlook called Baybers, who founded the dynasty of the Baharites, which conquered Syria, took Damascus, and put an end to the domination of the Abbaside caliphs. In 1382 Doulet el Memlook el Borgéeh, a Circassian Memlook, overthrew the Baharite dynasty, and founded the dynasty of the Circassian Memlooks, which, after losing all the conquests of the Baharites in Asia by the hands of the Ottomans, continued to rule Egypt till 1517, when Selim I., sultan of the Ottomans, marched into Egypt, defeated the Memlooks near Heliopolis, took Cairo, and put to death Tomaun Bey, the last of the Circassian dynasty. Selim however maintained or was obliged to maintain the Memlooks as a military aristocracy in Egypt. The Beys of the Memlooks, twenty-four in number, continued to be the governors of as many districts, though subject to a Pacha, appointed by the Porte, who resided at Cairo. The beys were elected by their own body. [Egypt, *Modern History of*.] This aristocracy continued to rule almost independent of the Porte till Bonaparte's invasion, when the bulk of Memlook cavalry was destroyed in several brilliant but useless charges upon the French squares supported by artillery, at the battle of the Pyramids, in July, 1798. [Bonaparte.] The remains of this once splendid body with their beys retreated into Upper Egypt. After the English and the Turks had reconquered Egypt in 1801, the Porte was no longer inclined to allow the Memlooks to retain their former authority, and the captain Pacha treacherously murdered several of the beys whom he had invited to a conference. At last, in 1811, Mehemet Ali, pacha of Egypt, by a similar contrivance, destroyed nearly all the remainder of them in the citadel of Cairo. A few escaped into Dongola, but the victorious troops of the Pacha pursued them, and they are now extinct as a body. The Memlooks were recruited entirely from Caucasian slaves. The office of bey was not hereditary, but elective among them. Their morals were very depraved: they were rapacious and merciless, and their extinction has been rather an advantage than a loss to humanity.

MAMERS. [Sarthe.]

MAMMA'LIA, MAMMALS, a term employed by Linnæus to designate those animals which suckle their young, and which, in our opinion, is far preferable to the term *Mammifères* generally used by the French zoologists. Mammals are vertebrated animals whose blood is red and warm, and whose system of circulation is double; whose fœtus, in most species,* is nourished in utero by means of a placenta; whose young, when born at the proper period, give signs of life at their birth, and are, in a state of nature, afterwards fed with milk secreted by the mammæ of the mother, till they are old enough to procure their food, or to have it supplied from other sources.

Linnæus, who makes the Mammalia the first class of the Animal Kingdom, gives the following definition:—*Heart* with two auricles and two ventricles; *blood* warm, red. *Lungs* respiring reciprocally. *Jaws* incumbent, covered, armed with teeth in most. *Penis* intrans viviparas, lactiferas. *Senses:* tongue, nostrils, eyes, ears, *papillæ* (touch). *Covering:* hairs, &c. *Support* (Fulcra): four feet, except in those which are entirely aquatic, in which the posterior feet are bound together (compedes) into the fin of the tail. *A tail* in most.

This class Linnæus divides into orders, principally resting on the basis of dentition. His name for the incisor teeth is *primores;* for the canine or cuspidate teeth, *laniarii;* and for the back or grinding teeth, *molares*.

The orders, which are six in number, are comprised in three sections, depending on the nature of the extremities. 1. The *Unguiculata*, containing the orders *Bruta*, *Glires*, *Primates*, and *Feræ*. 2. The *Ungulata*, comprising the *Belluæ* and *Pecora*. 3. The *Mutica*, consisting of the order *Cete* (Whales) only.

1. The *Primates* consist of the genera Homo, Simia, Lemur, and Vespertilio.

2. The *Bruta* comprise the genera Elephas, Trichechus, Bradypus, Myrmecophaga, Manis, and Dasypus.

3. Under the *Feræ* are arranged the genera Phoca, Canis, Felis, Viverra, Mustela, Ursus, Didelphis, Talpa, Sorex, and Erinaceus.

4. The *Glires* embrace the genera Hystrix, Lepus, Castor, Mus, Sciurus, and Noctilio.

5. The *Pecora* comprehend the genera Camelus, Moschus, Cervus, Capra, Ovis, Bos.

6. To the *Belluæ* belong the genera Equus, Hippopotamus, Sus, and Rhinoceros.

And 7. Under the order *Cete* are arranged the genera Monodon, Balæna, Physeter, and Delphinus.

For the history of the science relating to the arrangement of the *Mammalia* generally, the reader is referred to the article Mammalogy; and for the natural history and organization of the beings which form the class, to that article and the articles Man, Mammary Gland, Dentition, as well as the various titles referrible to the orders, families and genera belonging to the class in this work.

MAMMA'LOGY, a hybrid word, the roots being derived from the Latin and the Greek. Accordingly M. Desmarest has proposed the term *Mastology*, and M. de Blainville that of *Mastozoology*, as being entirely of Greek origin, and therefore of more legitimate construction. Vicious however as the word is, the term *Mammalogy* is in such general use by the zoologists of England and France, that it seems to be less objectionable to retain it, with all its faults, than to attempt to supersede it by another word, which, though it may be more correct, would be comparatively very little known.

Mammalogy then is the science which has for its object the study and classification of animals with *mammæ*, or teats, that is to say, Man, and quadrupeds properly so called, including the quadrumanous animals and Whales.

The objects of this science are numerically much less than those which constitute the other classes of animated beings; their bulk, as compared with that of the others, is generally speaking of greater volume, and their structure is more readily laid open by the knife of the zootomist; whilst, with the exception of those passages by which nature gradually passes from one form to another, the differences are more strongly marked. Their habits too are better known, and consequently they afford materials for classification capable of a comparatively certain arrangement.

To a certain extent the knowledge of mammalia and their nominal distinctions, as regards their habits and economical uses, must have been of the earliest date. The Holy Scriptures abound with passages to confirm this statement, if indeed it needed confirmation. Antient monuments too, long anterior to the times of the Greeks and Romans, speak the same language. When we come down to the times of

---

* A placenta does not exist in the Marsupials and the Monotremes.

Aristotle, we find that the science had not proceeded further than a knowledge of the external and internal structure of these animals, without any attempt at a systematic arrangement of them.* If we descend lower, we find the science in the same state, whether we consult the works of Pliny, or of the other ancient writers who followed Aristotle.

Conrad Gesner, though he treated of the Mammalia alphabetically in his 'History of Quadrupeds' (1551), finally divided them into groups, such as Monkeys, Horses, Deer, Oxen, &c., as indeed he did with regard to the oviparous quadrupeds (Tortoises, Lizards, Frogs, &c.).

Aldrovandus, Jonston, and the rest of that class of many volumists, seem to have followed Gesner as closely as the ancient writers followed Aristotle.

The first great step in system was made by our countryman John Ray, in his 'Synopsis Methodica Animalium' (1693), wherein he separated the *Mammalia* into two great classes, the *Ungulated*, or Hoofed animals, and the *Unguiculated*, or animals with nails or claws.

The *Ungulated* class are divided into—1, the *Solipedes*, as the horse; 2, quadrupeds with a divided hoof properly so called, as the ox or sheep; and 3, quadrupeds which have the foot divided into more than two parts, as the elephant.

The animals with a divided hoof are again subdivided into two sections: 1, *those which do not ruminate*, as the Swine; 2, *Ruminants*, which last consist of four genera, Sheep, Goats, *Stags or Deer*, and Oxen.

Those of the Unguiculated Mammals which have the nails wide and resembling those of man, such as the Apes or Monkeys, are separated from those which have the nails sharp and narrow. These last he separates into those which have a bifid foot, as the *Camels*, and into those which have a multifid one, which he names *Fissipedes*.

The *Fissipedes* are subdivided into—1, the *Analogous* group, which have more than two incisor teeth in each jaw, as the Lions or Great Cats, the Dogs, &c., or two incisors only, as the Beaver, the Hare, the Guinea Pigs, the Squirrels, the Marmots, &c.; 2, the *Anomalous* group, which have no teeth at all, as the *Tamandua*, and other Ant-eaters [Ant-eaters, vol. ii.], or which have teeth differing in form, in number, and position from those of the other Mammals, as the Hedgehogs, Armadillos, Moles, Sloths, &c.

Our limits will not permit us to do more than allude to the authors, and they were not few, who entered upon this branch of the science after Ray. Of these Seba may be considered one of the principal, and his work is justly appreciated for the number, and, generally speaking, for the accuracy of the well-executed plates which illustrate his voluminous work. But there now arose one who was eminently distinguished from the crowd of zoological authors. Linnæus, an outline of whose system we have already given [Mammalia], fixed the science upon a basis which his penetrating genius immediately saw was the secure one. He may be said to have invented a language admirably adapted for the wants of that science; and it is in this department that the great Swedish naturalist shines preeminently as a zoologist. In vain was the splendid genius of Buffon arrayed against him and his pupils; in vain did Klein, who seemed to live for no other purpose than to attack the Swede, publish his 'Quadrupedum Dispositio brevisque Historia Naturalis' (1751), wherein he separated the Mammalia into two groups, the Ungulated and Unguiculated, each consisting of five families; in vain did Brisson (1756) publish his 'Animal Kingdom divided into eleven Classes,' containing eighteen orders and forty-two genera, some of the latter well defined and still admitted; the philosophical system of Linnæus daily gained ground, and at length became almost the universal language of zoology.

About a year before the death of Linnæus (1777) Erxleben published his 'Systema Regni Animalis.' It contained several new genera, as for example *Papio*, *Cercopithecus*, *Cebus*, *Callithrix* (all at the expense of the great Linnæan genus *Simia*), *Lutra*, *Cavia*, *Glis*, *Spalax*, *Dipus*, *Antilope*, and *Hydrochærus*, all of which are still retained; and indeed his work, which should be in the hands of the student, seems to have been intended as a further development of the Linnæan system, and of the principles contained therein.

The excellencies of the work last mentioned are strongly contrasted with the edition of the 'Systema Naturæ' which Gmelin gave to the world in 1788. It is not passing a severe judgment to characterize it as a jumble of all that had been previously contributed to this department of zoology, and a farrago of species heaped together, without care, and in many instances without inquiry. The student whose lot it may be to follow out the synonyms of the Mammalia will perceive in what a labyrinth he gets involved as soon as he sets to work upon the names and references which swell out the 'Systema Naturæ' from the neat proportions which graced it when it left the hand of Linnæus, to the undigested and overladen mass which Gmelin has made it.

Previously to this visitation, a work of a very different character had made its appearance. In 1780 Professor Storr published his '*Prodromus*,' which gave a direction to those employed in classifying the Mammalia still in a great measure followed. He divided the class into three Phalanges: the first consisting of those Mammals which have feet proper for walking; the second, of those whose feet are fin-shaped, but with distinct toes; and the third, of those which have true fins without any apparent toes. These phalanges are separated into cohorts, orders, tribes, sections, and genera; and the system is well worthy the deep attention of the reader.

Boddaert (1785), in his 'Elenchus Animalium,' divided the Mammalia into two great groups, the *Terrestrial* and the *Aquatic*. In the first (*Terrestria*) he placed—I. The *Unguiculated Mammals* divided into two sections, α. The Quadrumana; β. The Unguiculata with long claws (Sloth, Bats, Armadillos, Pangolins, and other Ant-eaters). II. The *Carnivorous Mammals* (*Feræ*). III. The *Rodent Mammals* (Glires). IV. The *Ruminants*. V. *Ungulata* not ruminants (Hog, Horse, Tapir, Rhinoceros, and Elephant).

In the 2nd group (*Aquatilia*) were arranged the Hippopotamus, Beaver, Otter, Walrus, the Seals and Dugongs, and the Manatee. Not to detain the reader with the Anatomical System of M. Vicq-d'Azyr, which broke up the Mammalia into fifteen classes and thirty-eight genera, and is seldom referred to, we proceed to notice the system of Blumenbach, who separated the Mammalia into nine orders. I. *Bimanus* (Man). II. *Quadrumana* (Apes, Monkeys, and Macaucos). III. *Chiroptera* (Bats). IV. *Digitata*, consisting of three sections, the Rodents (Glires), the Carnivorous (*Feræ*), and the Edentata (Bruta). V. *Solidungula* (Horse, &c.). VI. *Bisulca* (Ruminants). VII. *Multungula* (Hog, Tapir, Elephant, Rhinoceros, &c.). VIII. *Palmipeda*, consisting of three sections, viz. the Rodent Palmipedes (Glires, Beavers), the Carnivorous Palmipedes (Seals, Otters), and the Edentate Palmipedes (Bruta, Ornithorhynchus, Walruses, Dugongs). IX. The *Cetacea* (Whales).

In 1798 Cuvier published his Elementary Table of Animals, which was afterwards further developed in his *Anatomie Comparée* and the *Règne Animal*. The method of this great zoologist bears considerable resemblance in some of its parts to the 'Prodromus' of Storr, as Cuvier himself remarks; it is so generally adopted that we shall presently give it in detail.

M. Desmarest (1804—'Dictionnaire d'Histoire Naturelle'), principally taking Cuvier and Storr for his guides, divided the Mammalia into three great sections. I. The Unguiculated Mammalia. II. The Hoofed Mammalia (Mammifères à sabots). III. The Finned Mammalia (Mammifères à nageoires), containing the orders Amphibia, Seals, Walruses, Dugongs, &c., and Cetacea (Whales). Our limits will not permit us to enter at length into the classification of M. Desmarest, which should however be carefully perused by the student.

We now proceed to lay before the reader Cuvier's arrangement after it had received the benefit of the joint labours of M. Geoffroy and himself, and as it finally left his hands in his last edition of the 'Règne Animal.'

Class Mammifères.

Order I. *Bimana*. Man.

Order II. *Quadrumana*. Two families. 1. Apes and Monkeys (Simia, Linn.). 2. Macaucos (Lemur, Linn.).

Order III. *Carnassiers*. Family 1. Cheiroptera (Bats). 2. Insectivora (Hedgehogs. Tenrecs. Tupaia. Shrews. Mygale. Chrysochloris. Talpa. Condylura. Scalops). 3. Carnivora. Tribe 1. Plantigrades. Bears (Ursus, Linn.). Raccoons (Procyon, Storr). Panda (Ailurus, F. Cuv.). Benturongs (Ictides, Valenciennes). Coatis (Nasua, Storr). Kinkajous or Pottos? (Cercoleptes, Illiger). Badgers (Meles,

---

* Aristotle's classification was a classification of organs, not a classification of animals.

Storr). Gluttons (Gulo, Storr). Ratels. Tribe 2. Digitigrades. Martins (Mustela, Linn.). Skunks (Mephitis, Cuv.). Otters (Lutra, Storr). Dogs (Canis, Linn.). Civets (Viverra). Genets (Genetta, Cuv.). Paradoxurus. Ichneumons (Herpestes, Illiger). Suricates (Ryzæna, Illiger). Crossarchus. Proteles. The last subdivision of the Digitigrades is composed of the Hyænas (Hyæna, Storr), and the Cats (Felis, Linn.), in which last the sanguinary development is at its height. Tribe 3. Amphibia. The Seals (Phoca, Linn.). The Walruses (Trichechus, Linn.).

Order IV. *Marsupialia.* Subdivision 1. Opossums (Didelphis, Linn., including Cheironectes, Illiger, and Thylacinus and Phascogale, Temminck). Dasyurus (Geoffroy). Perameles (Geoffroy). Subdivision 2. Phalangista (Cuv.), including the true Phalangers (Balantia, Illiger) and the flying Phalangers (Petaurus, Shaw; Phalangista, Illiger). Subdivision 3. The Potoroos, or Kangaroo Rats (Hypsiprymnus, Illiger). The Kanguroos (Macropus, Shaw; Halmaturus, Illiger). The Koalas (Lipurus, Goldfuss; Phascolarctos, Blainville). Phascolomys (Geoffroy).

Order V. *Rodentia.* The Squirrels (Sciurus, Linnæus, including Tamia? Illiger; Pteromys and Cheiromys, Cuvier). The Rats (Mus, Linnæus, including Arctomys, Gmelin; Spermophilus, F. Cuvier). The Souslik (Cynomys of Rafinesque); Myoxus, Gmelin; Echimys, Geoffroy (Loncheres, Illiger); Hydromys, Geoffroy; Capromys, Desmarest. The Rats properly so called, Mus, Cuv. The Jerbilles, Gerbillus, Desmarest; Meriones, Illiger; Meriones, F. Cuvier. The Hamsters, Cricetus, Cuv., and Arvicola, Lacépède. The Ondatras, Fisher, F. Cuv. The Field Rats and Mice, Arvicola, Cuv., Hypudæus, Illiger. The Lemmings, Georychus, Illiger; Otomys, F. Cuv. The Jerboas, Dipus, Gmelin; Helamys, F. Cuv.; Pedetes, Illiger; Spalax, Guldenstädt; Bathyergus, Illiger; Geomys, Rafinesque; Pseudostoma, Say; Axomys, Lichtenstein; Diplostoma, Rafinesque. The Beavers (Castor, Linnæus). Myopotamus, Commerson. The Porcupines (Hystrix, Linnæus, including the Ursons, Erétisons of F. Cuv., and the Coendous, Synetheres of F. Cuv.). The Hares (Lepus, Linnæus, including Lagomys, Cuvier). The Capybara, Hydrochœrus, Erxleben. The Guinea Pigs (Anœma, F. Cuv., Cavia, Illiger, including Keradon, F. Cuv.). The Agoutis (Chloromys, F. Cuv., Dasyprocta, Illiger). The Pacas (Cœlogenys, F. Cuv.); and the Chinchillas.

Order VI. *Edentata.* Tribe 1. Tardigrades. The Sloths* (Bradypus, Linnæus, including Acheus, F. Cuv.). Tribe 2. Ordinary Edentata. The Armadillos (Dasypus, Linnæus), and the subgenus Chlamyphorus, Harlan. The Aard-Vark (Orycteropus, Geoffroy). The Ant-Eaters (Myrmecophaga, Linnæus). The Pangolins (Manis, Linnæus). Tribe 3. The Monotremes. The Echidna, Cuv. (Tachyglossus, Illiger), and the Ornithorhynchus, Blumen. (Platypus, Shaw.).

Order VII. *Pachydermata.* Family 1. Proboscidians. Elephants (Elephas, Linnæus) and Mastodons† (Mastodon, Cuvier). Family 2. Ordinary Pachydermata. Hippopotamus (Linn.). The Hogs (Sus, Linnæus, including Phascochœres, F. Cuvier, and Dicotyles, Cuv.). Anoplotherium (Cuv., extinct). The Rhinoceroses (Rhinoceros, Linnæus). The Damans (Hyrax, Hermann). Palæotherium (Cuv., extinct). Lophiodon (Cuv., extinct). The Tapirs (Tapir, Linnæus). Family 3. Solipeda. The Horses, &c. (Equus, Linn.).

Order VIII. *Ruminantia* (Pecora, Linnæus). *No Horns.* The Camels (Camelus, Linnæus, including the Llamas, Auchenia, Illiger). The Musks (Moschus, Linnæus). * * *True Horns shed periodically.* The Stags or Deer (Cervus, Linnæus). * * * *Persistent Horns.* The Giraffe (Camelopardalis, Linnæus). * * * * *Hollow Horns.* The Antelopes (Antilope). The Goats (Capra, Linnæus). The Sheep (Ovis, Linnæus). The Oxen (Bos, Linnæus).

Order IX. *Cetacea.* Family 1. Herbivorous Cetacea. The Manatees (Manatus, Cuvier). The Dugongs (Halicore, Illiger). Rytina (Illiger). Family 2. Ordinary Cetacea. The Dolphins (Delphinus, Linn., including Delphinus, Cuvier, Delphinorhynchus, Blainville). The Porpoises (Phocæna, Cuv.). Delphinapterus, Lacépède, Hyperoodon, Lacépède. The Narwhals (Monodon, Linnæus). The Cachalots (Physeter, Linnæus). The Whalebone Whales (Balæna, Linnæus, including Balænoptera, Lacépède).

Illiger (1811), in his 'Prodromus Systematis Mammalium et Avium,' divided the Mammalia into fourteen orders, thirty-nine families, and one hundred and twenty-five genera, most of which last are characterised with great neatness. We have only room for a mere sketch of this system, which has considerable merit.

Order I. *Erecta* (Man).

Order II. *Pollicata.* Family 2. Quadrumana (Apes and Monkeys). Family 3. Prosimia (the Lemurs, &c.) Family 4. Macrotarsi (Tarsiers, Galago, &c.). Family 5. Leptodactyle (Cheiromys). Family 6. Marsupialia (except the Potoroos and Kangaroos).

Order III. *Salientia.* Family 7. Salientia (Hypsiprymnus and Halmaturus, Potoroos and Kangaroos).

Order IV. *Prensiculantia.* Fam. 8. Macropoda (Jerboas, &c.). Fam. 9. Agilia (Myoxus, the Squirrels, and Pteromys). Fam. 10. Murina (Marmots, Hamsters, Rats, &c.). Fam. 11. Cunicularia (Lemmings, Hypudæus, &c.). Fam. 12. Palmipeda (Hydromys and Beavers). Fam. 13. Aculeatea (Porcupines and Loncheres, or Echimys). Fam. 14. Duplicidentata (Hares, &c.). Fam. 15. Subungulata (Paca, Agoutis, Guinea Pigs, Capybara).

Order V. *Multungulata.* Fam. 16. Lamnungua (Hyrax, &c.). Fam. 17. Proboscidea (Elephants). Fam. 18. Nasicornia (Rhinoceroses). Fam. 19. Obesa (Hippopotamus). Fam. 20. Nasuta (Tapirs). Fam. 21. Setigera (Hogs).

Order VI. *Solidungula.* Fam. 22. (Horse, &c.)

Order VII. *Bisulca.* Fam. 23. Tylopoda (Camels and Llamas). Fam. 24. Devexa (Giraffe). Fam. 25. Capreoli (Deer and Musks). Fam. 26. Cavicornia (Antelopes, Goats, and Oxen).

Order VIII. *Tardigrada.* Fam. 27. Tardigrada (Sloths, tridactylous and bidactylous, Sloth-Bear or Prochilus).

Order IX. *Effodientia.* Fam. 28. Cingulata (Armadillos). Fam. 29. Vermilinguia (Aard-Vark, Ant-Eaters and Pangolins).

Order X. *Reptantia.* Fam. 30. Reptantia (Monotremes and Pamphractus, which last is no mammal, but a tortoise).

Order XI. *Volitantia.* Fam. 31. Dermoptera (Galeopithecus). Fam. 32. Cheiroptera (Bats).

Order XII. *Falculata.* Fam. 33. Subterranea (Hedgehogs, Shrews, Moles, &c.). Fam. 34. Plantigrada (Kinkajou, Coatis, Raccoon, Glutton, Badgers, and Bears). Fam. 35. Sanguinaria (Fennec, Dogs, Hyænas, Cats, Civets, and Suricate). Fam. 36. Gracilia (Ichneumons, Skunks, Weasels, Otters).

Order XIII. *Pinnipedia.* Fam. 37. Pinnipedia (Seals and Walruses).

Order XIV. *Natantia.* Fam. 38. Sirenia (Manatee, Dugong, and Rytina). Fam. 39. Cete (Whalebone Whales, Narwhals, Cachalots, Dolphins, &c.).

M. de Blainville (1816) divided the *Mammifères* into two subclasses. 1. The *Monodelphes*, containing the six orders Quadrumana, Carnassiers, Edentata, Rodentia, Gravigrades, and Ongulogrades. 2. The *Didelphes.* All the orders of the *Monodelphes*, with the exception of the fourth and fifth, are subdivided into the *Normal* and *Anomalous*, and so in the subclass of Didelphes, the Normal forms being the *Carnassiers* and *Rongeurs*, and the Anomalous *Echidna* (for burrowing) and *Ornithorhynchus* (for swimming). M. de Blainville observes that it may be that the *Cetacea* should form a separate order or degree of organization; and that the *Echidnæ* and *Ornithorhynchi* may make a distinct subclass.

In 1825 Mr. Gray published his 'Outline of an Attempt at the Disposition of Mammalia into Tribes and Families, with a List of the Genera apparently appertaining to each Tribe.' For the details we must refer the reader to the 'Annals of Philosophy' (vol. xxvi.), confining ourselves to a mere sketch of the orders, families, and subfamilies.

§ 1. Teeth of the three distinct sorts, and forming a continuous series.

Order I. Primates (Linn.).

*

Anthropomorphous.

Family 1. *Hominidæ.* Subfamilies: 1. Hominina (Man). 2. Simiina (Apes). 3. Presbytina (Presbytes). 4. Cercopithecina (Cercopithecus, &c.). 5. Cynocephalina (Cynocephalus and Papio).

---

* It is here that Cuvier mentions the extinct genera Megatherium and Megalonyx, noticing however the differences, and observing that the former, though it has a skull very like the sloths, wants the canines, and inclines, as to the rest of the skeleton, partly to the sloths, and partly to the ant-eaters.

† Extinct.

Fam. 2. *Sariguidæ.* Subfam. 1. Mycetina (Mycetes). 2. Atelina (Ateles, &c.). 3. Callithricina (Callithrix). 4. Saguinina (Saguinus, &c.). 5. Harpalina* (Jacchus and Midas).

** Quadrupedal.

Fam. 3. *Lemuridæ.* Subfam. 1. Lemurina (Lemur). 2. Lichanotina (Indris, Lichanotus). 3. Loridina (Loris, Nycticebus). 4. Galagonina (Otolicnus, &c.). 5. Tarsina (Tarsius). 6. Cheiromina (Cheiromys).

Fam. 4. *Galeopithecidæ.* Galeopithecus.

Fam. 5. *Vespertilionidæ.* Subfam. 1. Rhinolophina (Megaderma, &c.). 2. Phyllostomina (Phyllostoma, &c.). 3. Pteropina (Pteropus, &c.). 4. Noctilionina (Noctilio, &c.). 5. Vespertilionina (Vespertilio, Barbastellus, &c.).

Order II. Feræ (Linn.)

* Cutting-teeth six above and below; grinders of three sorts.

Fam. 1. *Felidæ.* Subfam. 1. Hyænina (Hyæna and Proteles). 2. Felina (Felis, Lynchus, Prionodon). 3. Mustelina (Putorius, &c., and Lutra). 4. Viverrina (Viverra, &c.). 5. Canina (Canis, Fennecus, Lycaon).

Fam. 2. *Ursidæ.* Subfam. 1. Ursina (Ursus, &c.). 2. Procyonina (Procyon, &c.). 3. Gulonina (Gulo, &c.). 4. Mydaina† (Mydaus). 5. Taxina (Meles).

** Cutting-teeth various (rarely six above and below); grinders of two sorts, false and tubercular.

Fam. 3. *Talpidæ.* Subfam. 1. Talpina (Talpa). 2. Chrysochlorina (Condylura, &c.). 3. Sorecina (Sorex, Mygale). 4. Erinacina (Erinaceus). 5. Tenrecina (Tenrecus). 6? Tupaina (Tupaia).

Fam. 4. *Didelphidæ.* Subfam. 1. Macropina (Macropus, &c.). 2. Phalangistina (Acrobata, Petaurus, &c.). 3. Phascolomina (Phascolomys). 4. Didelphina (Didelphis, Cheironectes). 5. Dasyurina (Peracyon, Dasyurus, Phascogale). 6. Peramelina (Perameles and Isodon).

Fam. 5. *Phocidæ.* Subfam. 1. Stenorhyncina (Pelagius, Stenorhynchus). 2. Phocina (Phoca). 3. Enhydrina (Enhydra). 4. Otarina (Otaria, Platyrhynchus). 5. Stemmatopina (Stemmatopus and Macrorhinus).

§ 2. Teeth not of three sorts, or not forming a continuous series.

Order III. Cete (Linn.).

* Skin smooth without any hair or whiskers.

Fam. 1. *Balænidæ.* Subfam. 1. Balænina (Balæna, Balænoptera). 2. Physeterina (Physalus, Physeter, Catodon).

Fam. 2. *Delphinidæ.* Subfam. 1. Delphinina (Delphinus, Delphinorhynchus). 2. Phocænina (Phocæna, &c.).

** Skin rather hairy, whiskers distinct; grinders flat-topped.

Fam. 3. *Trichecidæ.* Trichecus.

Fam. 4. *Manatidæ.* Manatus.

Fam. 5. *Halicoridæ.* Halicore, Stellerus.

Order IV. Glires (Linn.).

* *Fur with scattered larger hairs or spines; tail spiny or scaly.*

Fam. 1. *Muridæ.* Subfam. 1. Murina (Mus, &c.). 2. Hydromina (Hydromys). 3. Ondatrina (Ondatra). 4. Castorina (Castor, Ostmopora). 5. Echymina (Echymys, &c.).

Fam. 2. *Hystricidæ.* Hystrix, &c.

** *Fur nearly equally soft; tail none, or hairy.*

Fam. 3. *Leporidæ.* Subfam. 1. Leporina (Lepus). 2. Lagomina (Lagomys). 3. Cavina (Cavia, Kerodon). 4. Hydrochærina (Hydrochærus). 5. Dasyproctina (Cœlogenys, &c.).

Fam. 4. *Jerbidæ.* Subfam. 1. Pedetina (Pedetes). 2. Dipina (Dipus, Meriones (F. Cuv., not Illiger)). 3. Gerbillina (Gerbillus). 4. Myoxina (Myoxus). 5. Sciurina (Sciuropterus, Sciurus, &c.).

Fam. 5. *Aspalacidæ.* Subfam. 1. Aspalacina (Orycterus, &c.). 2. Lemmina (Arvicola, Lemmus, &c.). 3. Cricetina (Cricetus). 4. Pseudostomina (Pseudostoma, &c.). 5. Arctomina (Arctomys, Spermophilus).

Order V. Ungulata (Ray). Bruta, Pecora, Belluæ (Linn.).

* Two middle toes large, equal; bones of the metacarpus and metatarsus united.

Fam. 1. *Bovidæ.* (Horns persistent.) Subfam. 1. Bovina (Bos, Ovis, Capra, Antilocapra, Antilope, Catoblepas). 2. Camelopardina (Camelopardalis). (Horns none, or deciduous.) 3. Camelina (Camelus and Auchenia). 4. Moschina (Moschus and Memina). 5. Cervina (Cervus, Muntjacus, &c.).

Fam. 2. *Equidæ.* Equus (Linn.). Asinus (Gray).

** Toes three, four, or five to each foot, nearly equal; teeth nearly in one series.

Fam. 3. *Elephantidæ.* (Nose extended into a trunk.) Subfam. 1. Elephantina (Elephas, Mastodon). 2. Tapirina (Tapirus, Lophiodon, Palæotherium). (Nose not produced into a trunk.) 3. Rhinocerina (Rhinoceros, Hyrax, Lipura and Elasmotherium, Anoplotherium, &c.). 4. Suina (Sus, &c.). 5. Hippopotamina (Hippopotamus).

Fam. 4. *Dasypidæ.* (Body covered with scales and armour, revolute.) Subfam. 1. Manina (Manis, Dasypus, &c.). (Body hairy or spinous, not revolute.) 3. Orycteropina (Orycteropus). 4. Myrmecophagina (Myrmecophaga, &c.). 5. Ornithorhynchina (Echidna, Ornithorhynchus).

Fam. 5. *Bradypidæ.* Bradypus, Cholœpus, Megatherium, Megalonyx.

Mr. Gray then exhibits the manner in which the orders appear to be connected together, and the 'Typical' and 'Annectant Groups' of each order.

Mr. Swainson, who does not admit Man into the zoological circle for reasons stated in his 'Natural History and Classification of Quadrupeds' (1835), gives in the third part of his book an arrangement of 'The Class Mammalia, according to its natural affinities.' He makes the *Quadrumana*, the first order, consist of the following families:—1, Simiadæ. 2, Cebidæ. 3, Lemuridæ. 4, Vespertilionidæ, consisting of Mr. Gray's subfamilies *Rhinolophina*, Phyllostomina, Pteropina, Noctilionina, and Vespertilionina.

The second order, *Feræ*, includes the families—1, Felidæ. 2, Mustelidæ, consisting of the subfamilies Viverrinæ (Viverrinæ), Mustelinæ, and Ursinæ. 3, Didelphidæ (Opossums). 4, Soricidæ. 5, Phocidæ.

The third order, *Cetacea*, comprehends the families—1, Sirenia (Herbivorous Cetacea). 2, *Cete*, with the subfamilies? Delphinæ and Balaninæ.

The fourth order, *Ungulata*, embraces—tribe 1, Pachydermes. Tribe 2, Anoplotheres. Tribe 3, Edentates, including the Monotremes. Tribe 4, Ruminantes (comprehending the families—1, Bovidæ. 2, Antilopidæ. 3, Cervidæ. 4, Moschidæ. 5, Camelopardidæ). Tribe 5, Solipedes.

The fifth order, *Glires*, consists of—division 1, Glires proper, with clavicles. Div. 2, Clavicles rudimentary or none.

Immediately following the genus Cavia and its subgenera we find the '*Marsupial Rodents.* Situation uncertain;' and next to them the family 'Marsupidæ' (Herbivorous Marsupials), formed of the genera Halmaturus, Hypsiprymnus, and Phalangista, the latter with two subgenera, Petaurista and Petaurus.

We must refer the reader to Mr. Swainson's book for an explanation of the peculiar views of classification, affinity, and analogy developed in it.

The works of Buffon can hardly be said to present any principle of classification as applicable to the Mammalia. Pennant indeed gives what he calls a systematic index of the genera, species, and varieties, and divides the Quadrupeds into two grand divisions (the first without a name, and including—1, Horse; 2, Ox; 3, Sheep; 4, Goat; 5, Giraffe; 6, Antelope; 7, Deer; 8, Musk; 9, Camel; 10, Hog; 11, Rhinoceros; 12, Hippopotame; 13, Tapir; 14, Elephant, as generic appellations; and the second grand division, with the name of Digitated Quadrupeds, including the genera (Section 1)—15, Ape; 16, Maucauco; (Section 2)—17, Dog; 18, Hyæna; 19, Cat; 20, Bear; 21, Badger; 22, Opossum; 23, Weesel; 24, Otter; (Section 3)—25, Cavy; 26, Hare; 27, Beaver; 28, Porcupine; 29, Marmot; 30, Squirrel; 31, Jerboa; 32, Rat; 33, Shrew; 34, Mole; 35, Hedgehog; 36, Sloth; 37, Armadillo; 38, Manis; 39, Ant-Eater; 40, Walrus; 41, Seal; 42, Manati; 43, Bat); but this catalogue can hardly be called systematic. In his later editions he formed his catalogue into a more complete 'Method,' with four grand divisions—1, Hoofed Quadrupeds; 2, Digitated; 3, Pinnated; 4, Winged; but his work will always be consulted more for the natural history of the 'Quadrupeds' therein treated of, than for their arrangement.

* [illegible] ?

† [illegible] ? [illegible] ?

We can only allude to the works of Pallas, Allamand, Schreber, Shaw, Marcgrave, Catesby, Hernandez, D'Azara, Sonnerat, Steller, Sparrman, Le Vaillant, Bruce, Barrow, Burchell, Humboldt, Peron, Lesueur, Fischer, Lesson, Rüppell, Smith, Bennett, Bell, Owen, Ogilby, Sykes, Darwin, and a host of others, who have enriched the subject by their writings or the observations which they have made in their travels.

MAMMARY GLAND is an organ of considerable interest from its occurring only in that important class of animals to which it gives its name [Mammalia], and whose greatest peculiarity is that, while young, their food is the milk secreted by the mammary gland of their mother.

The number of mammary glands varies in different animals. They are composed of ramified ducts which open on the surface of a nipple or teat by a very minute orifice. In some animals, as ruminants, there is but one orifice at the extremity of each nipple; in others, and in man, there are several. Each orifice leads into a fine canal, which however soon dilates, and ramifies with irregular and tortuous branches in the substance of the breast or udder. Each branch has either a simple closed extremity or terminates in a minute cellule, and numerous capillary blood-vessels ramify on their walls and secrete the milk into them. When the mouth of the young animal, by the action of sucking, produces a partial vacuum over the nipple, the weight of the surrounding medium presses lightly and equally upon the surface of the breast or udder, and propels the milk from the ducts in minute and gentle streams.

At the commencement of pregnancy, the mammary gland, which up to the period of puberty had been but little developed, enlarges; its increase of size keeps pace with the progress of gestation, and before its termination a thin serous milky fluid begins to be secreted. Directly after parturition, the quantity of milk increases, and it becomes more thick and rich, combining in itself all the best principles for the nourishment of the young animal. It continues to flow for a length of time proportioned to the age at which the young animal can seek its own food, and then gradually subsiding, the gland decreases to the same size which it had before pregnancy.

In women the mammary gland is subject to many and severe diseases; as abscess, cancer, and various tumours; but the consideration of these belongs to other general articles. In males of all species only a rudiment of this organ is found; yet there are not wanting instances in which milk has been secreted from the breasts of men and other male animals. (Blumenbach.)

MAMMEA, a genus of the natural family of Guttiferæ, so called from the American name *Mamey* of *M. Americana*, or the American Mammee-tree, which is the only species of this genus, and forms a handsome tree with a spreading elegant head, which is compared with that of a Magnolia. The flowers are odoriferous and employed as an aromatic addition to liqueurs called *Eau* and *Crême des Creoles* in some of the West India Islands. The fruit is large and has a double rind, of which the outer is thick and leathery; the inner one is thin and bitter, and contains the pulp closely adhering to it, which is of a yellow-apricot colour, whence it is sometimes called abricot de Saint Domingue. This pulp has a pleasant but peculiar taste with an aromatic smell; it may be eaten raw, or cut in slices with wine or sugar; or cooked, which deprives it of its gummy portion. It is also preserved in wine sweetened with sugar, or in brandy. (Labat.) The fruit is considered nourishing and pectoral, and much esteemed in America. Attempts have been made to cultivate it in stoves in this country. According to Sweet, it grows freely in sandy loam; and ripened cuttings, with the leaves not shortened, root in sand under a hand-glass in heat.

MAMMELLI'PORA. Bronn chooses this name instead of Lymnorea, Lam., for a genus of fossil zoophyta, analogous to Alcyonium.

MAMMOTH, a term employed to designate the fossil elephants. The name has been erroneously applied sometimes to the Mastodon. [Elephant, vol. ix., p. 352.]

MAMUN, ABUL ABBAS ABDALLAH, the seventh Abbaside caliph, was born at Bagdad, A.D. 786. He was entrusted, during the life of his father, the celebrated Harun al Rashid, with the government of Khorassan; but on the death of Al Rashid, in 808, and the succession of his brother Amin, Mamun was deprived of this government, and commanded to repair to Bagdad. But as such a step would doubtless have been followed by his death, Mamun disobeyed the orders of the caliph, and proclaimed war against him. The contest was carried on till 813; when Bagdad was taken by Thaher and Harthemah, the general of Mamun, and Amin put to death.

The early part of Mamun's reign was greatly disturbed by the pretensions of the descendants of Ali, the cousin of Mohammed. [Ali.] Mamun, in order to restore peace to his empire, named one of the princes of the house of Ali as his successor, and commanded that the black colour, which distinguished the Abbasides, should be discontinued at the court, and replaced by the green, which was worn by the descendants of the prophet. This step however occasioned a revolution in the government; the Abbasides rose against their caliph and proclaimed in his stead Ibrahim, the son of Mahadi. After the end of two years, Mamun obtained the caliphate again, and, taught by experience, restored the black colour of the Abbasides and named his brother as his successor. The partisans of the Alides again rebelled against Mamun, but were unable to obtain any advantages over him. In addition to these wars, Mamun was also engaged, during part of his reign, by the revolt of the son of Harthemah in Armenia, and by that of Thaher in Persia.

In 830 Mamun engaged in a war with Theophilus, the emperor of Constantinople; which is said to have arisen from the refusal of the emperor to allow Leon, a celebrated teacher at Constantinople, to repair to Bagdad, whither he had been invited by the caliph. The war was carried on, principally in Cilicia, during three successive campaigns, at the close of which Mamun died in the vicinity of Tarsus, 833, and was succeeded by his brother Motasem.

Although the reign of Mamun was disturbed by so many wars and intestine commotions, yet science and literature were more extensively cultivated than under any preceding caliph. Mamun was a munificent patron of literature; he founded colleges and libraries in the principal towns of his dominions; and invited to his court not only Greek and Syriac, but also Hindu philosophers and mathematicians. Many of the most celebrated Greek and Hindu works were translated into Arabic by his command; and among other works written during this time, we may mention an 'Elementary Treatise on Algebra,' by Mohammed ben Musa, which was published with a translation by the late Dr. Rosen. [Abbasides.]

MAN. The anatomy and physiology of man are treated of under their several and appropriate heads in this work. The present article is limited to the consideration of Man as an object of natural history. The subject may be divided into two parts: 1, The comparison of the human structure and economy with those of other animals; and 2, The comparison of the various modifications of the human structure and economy in different races of men.

Specific Characters of Man.—In every part of the human frame we find adaptations to the erect attitude, the most peculiar characteristic of mankind. Examining the skeleton, we find that the two condyles, or articulating surfaces of the occiput, by which the skull is connected with the spine, are so placed on each side, that a vertical line passing through the centre of gravity of the head would fall almost exactly between them and on the top of the spine. The condyles are not placed at the very centre of the base of the skull, but just behind it, so as to compensate in some measure for the greater specific gravity of the posterior part of the head, which is composed chiefly of thick heavy bone and brain, while the anterior is formed in part by the light bones of the face, and contains numerous cavities. Still however there is a slight preponderance in front of the condyles, which, when the head is not held up by some external force, tends to carry it forwards and downwards, as we may see in persons falling asleep in the erect posture. But the muscles attached to the back of the head are far larger and more numerous, as well as more conveniently arranged for the full exercise of their power, than those in front of the condyles, and the effort required of them to hold up the head is so slight, that it may be made throughout the day without producing fatigue.

The surfaces of these condyles moreover have a horizontal direction (when the head is held upright), and thus the weight of the skull falls vertically upon them and the top of the vertebral column. Comparing with these arrangements the position and direction of the occipital condyles in other mammalia, we find that in the latter they are placed much nearer the back of the head, and that their plane is mammalia. Thus, if a line be drawn in the median plane along the base of a human skull, the foramen magnum and occipital condyles will be found immediately behind the point at which that line is bisected; while in the chimpanzee (in which also the condyles are proportionally smaller) the same parts are placed in the middle of the posterior third of a line similarly drawn, and in other animals are still farther back. Hence there is in all animals a greater proportion of the weight of the head in front of the vertebral column than there is in man; and all the parts anterior to the condyles are proportionally shorter in man than in other mammalia, in which the jaws, the bony palate, the basilar part of the occipital bone, and the petrous portions of the temporal, are always long and large.

Besides being placed so far behind the centre of gravity of the head, the condyles of other mammalia are directed more obliquely downwards than those of man; so that, if the head were supported on the top of a vertical column, its weight (even if it fell entirely upon the condyles) would press on an inclined plane, and constantly tend to carry the head forwards and downwards. The degree of obliquity in the direction of the condyles varies in different animals. It may be nearly estimated by the angle formed by two lines, one of which is drawn in the plane of the occipital foramen, and the other from its posterior edge to the lower margin of the orbit. This angle is of 3° in man, and of 37° in the orang-outan; but in the horse it is 90°, the plane of the foramen being vertical. If therefore the natural posture of man were horizontal he would in this respect be circumstanced like the horse, for the plane of his condyles, which is nearly horizontal in the upright position, would then be vertical; the head, instead of being nearly balanced on the top of the column, would hang at the end of the neck, and its whole weight would have to be supported by some external and constantly-acting power. But for this there is neither in the skeleton nor in the muscular system of man any adequate provision. In other mammalia the head is maintained in such a position by a strong and thick ligament (the ligamentum nuchae), which passes from the spines of the cervical and dorsal vertebrae to the most prominent part of the occiput, but of which in man there is little or no trace. In the horizontal position therefore he would have the heaviest head, with the least power of supporting it.

The position of the *face* immediately beneath the brain, so that its front is nearly in the same plane as the forehead, is peculiarly characteristic of man; for the crania of the chimpanzee and orang, which approach nearest to that of man, are altogether posterior to and not above the face. This form, at the same time that it remarkably distinguishes the human from the brute features, is exactly adapted to the erect attitude. In that posture the plane of the orbits is nearly horizontal; the cavities of the nose are in the best direction for inhaling odours, proceeding from before or from below them; the jaws do not project in front of the forehead and chin. But suppose the posture changed, as painful an effort would be required to examine an object in front of the body as is now necessary to keep the eyes fixed on the zenith, and the heavens would be almost hidden from our view; the nose would be unable to perceive any other odours than those which proceeded from the earth or from the body itself, and the teeth and lips would be almost useless, for they would scarcely touch an object on the ground before the forehead and chin were in contact with it; while the view of that which they attempted to seize would be obstructed by the nose and cheeks.

The vertebral column in man, though not absolutely straight, yet has its curves so arranged, that when the body is in the erect posture, a vertical line drawn from its summit would fall exactly on the centre of its base. It increases in size to the lumbar region, and is therefore somewhat pyramidal in form. The lumbar portion of the human vertebral column is also of considerable length, and is composed of five vertebrae; while in the chimpanzee and orang there are but four. The processes for the attachment of muscles upon it are long and strong; an arrangement well adapted to overcome the tendency which the weight of the viscera in front of the column has to draw it forwards and downwards. Thus the spinous processes of the cervical and dorsal vertebrae, which are in other mammalia large and strong for the attachment of the ligamentum nuchae to support the head, are in man scarcely prominent, and his head is nearly balanced on the vertebral column; while those of the lumbar vertebrae, by which the weight of the thoracic and abdominal viscera is partly supported, are proportionally much larger in man than in other mammals.

The base of the human vertebral column is placed on a sacrum of greater proportional breadth than that of any other animal, and remarkably arched forwards. The sacrum is again fixed between two widely-expanded haunch-bones, forming the lateral walls of a peculiarly broad pelvis. By its great width the pelvis forms an ample cavity for the support and defence of many of the viscera and especially of the pregnant uterus; by the distant separation of the haunches and thighs the basis of support is rendered wider, and by its oblique direction the weight of the body is transmitted more directly from the sacrum to the upper part of the thigh-bones. The pelvis of every other species of the class is very different from the human; it is always longer and narrower, having a far smaller space between the iliac bones and the lowest ribs; the sacrum especially is lengthened and reduced in width; the alae of the ilia are much less expanded; and the whole pelvis, instead of forming an angle with the vertebral column, is almost in the same line with it.

The lower extremities of man are remarkable for their length, which is proportionally greater than that of any other mammal, except those of the kangaroo tribe. Now it is evident that no greater obstacle to progression in the horizontal posture could exist than this length of what would then be the hind legs. Either man would be obliged to rest on his knees, with his thighs so bent towards the trunk, that an attempt to advance them would be painful, and with his legs and feet immoveable and useless; or he must elevate his trunk upon the extremities of his toes, throwing his head downwards, and exerting himself forcibly at every attempt to bring forward the thighs by a rotatory motion at the hip-joint. In either case the only useful joint would be that at the hip, and the legs would be scarcely superior to wooden or other rigid supports.

The position of the human thigh-bone, in which it is most securely fixed in its deep acetabulum, is that which it has when supporting the body in the erect attitude. In the chimpanzee and orang-outan its analogous position is at an oblique angle to the long axis of the pelvis, with the body supported obliquely in front of it; in other animals, as the elephant, it forms nearly a right angle; and in others, as the horse, ox, &c., an acute angle with the axis of the pelvis and spinal column. The human femur is further distinguished by its great length, by the obliquity and length of its neck, and by its being directed somewhat obliquely inwards towards that of the opposite side, so as to approximate the knees and bring them more directly under the pelvis. It is by this great length of the thigh that the proportion in the length of the human thigh and arm is so different from that which obtains in the apes, among which, in the chimpanzee, the arms reach to the level of the knees, and in the orang-outan to the ancles; while in man they extend only to the middle of the thighs. In all other animals the thigh is still shorter.

In the human knee-joint we find the opposed extremities of the femur and tibia expanded so as to present a very broad articulating surface; and the internal condyle of the femur lengthened, so that the whole weight of the body, when erect, falls vertically on the top of the tibia, when the joint is in the firmest position in which it can be placed.

The weight of the body is next transmitted through the tibia to the upper convex surface of the astragalus, and thence to the other bones of the foot.

The human foot is, in proportion to the size of the whole body, larger, broader, and stronger than that of any other mammal. In the upright position it is at right angles with the leg, and is in contact with the ground at both ends. The sole of the foot is concave, so that the weight of the body falls on the summit of an arch, of which the astragalus (supported below by a very strong ligament), represents the key-stone, and of which the principal points of support are the large and arched os calcis, and the anterior extremities of the metatarsal bones. This strength and size of his foot enable man alone of all mammalia to stand upon one leg. The natural contact of the os calcis with the ground, and its arched form, are also peculiar to him. All the apes have the os calcis small, straight, and more or less raised from the ground, which, when standing, they touch only with the outer side of the rest of the foot; while in animals more remote from man the angle which the os calcis forms with the tibia is still more acute; and the foot being more elongated and narrow, the extremities of the toes only come in contact with the ground. The foot of the monkey is still further distinguished from that of man by the great length of four of its toes, and the separation of the most internal (which, instead of being the largest, is the smallest) from the rest, in such a manner that it can be opposed to them in action, like a thumb. Monkeys are hence four-handed, all their extremities being alike adapted for prehension, and for clinging to small bodies, as the branches of trees, &c.

Man's chest is large and expanded. It is flattened in front, and has greater dimensions transversely than in depth, a peculiarity in which only the most man-like monkeys partake. The sternum is short and broad, and there is a considerable distance between the lower ribs and the haunch-bones, in consequence of the small number of ribs and the length of the lumbar portion of the vertebral column. The viscera in this space, which in the horizontal position would be but insufficiently held up by the abdominal muscles, are in the erect attitude securely supported by the expanded pelvis.

In the upper or anterior extremity of man we find ample proofs of his naturally erect attitude, though some of them are only of a negative kind, as those drawn from the total unfitness of the arm and hand to be an organ of support; and others only presumptive, as those relating to the necessity of the upright posture for the full exercise of the hands. But the peculiarities of the upper extremity of man, in relation to his being the only two-handed animal, are sufficiently interesting to require a separate description.

The other parts of the human body concerned in locomotion are in exact adaptation with the peculiar construction of the skeleton. The superior power of the muscles, tending to draw the head and spine backwards, has been already referred to; the glutei, by which the pelvis is fixed on the thighs, and by which the principal outward motions of the legs are performed, are very large, forming the buttocks, which are peculiar to man; the extensors of the legs are more powerful than the flexors, an arrangement which is the reverse of that of other animals; the gastrocnemii, from which such powerful exertions are constantly required to raise the whole weight of the body by drawing up the heel, as in walking, jumping, &c., form a large mass, the calf, which, like the buttock, is found in no other animal; the flexor longus pollicis muscle is attached only to the great toe, on which the weight of the body is so often supported; while in the chimpanzee and orang, which, in so many other respects resemble the human form, it is affixed to the three middle toes; the serratus magnus, which, like a sling between the scapulæ, supports the front of the trunk of quadrupeds, is proportionally small in man.

In the preceding observations, at the same time that the peculiarities of the human skeleton have been pointed out, sufficient evidence has probably been adduced to prove that the erect attitude is that to which the structure of man, but of no other mammal, is best adapted. Yet some have argued the contrary from the histories and fables of some supposed wild men, who, it has been said, were found in woods, dumb, hairy, and crawling on all-fours, and who have been considered as specimens of man, unaltered by civilisation, in a state of original nature. (See the histories of Peter the Wild Boy and others in Blumenbach's *Beyträge zur Naturgeschichte;* Monboddo's *Antient Metaphysics,* &c.) It is sufficient to say that in the very few cases of the kind for which there is any authority, it has been clearly proved that they were merely idiotic or otherwise deficient children, who had been lost or exposed by their parents; and that the authors who state them to have been either quadruped or hairy are altogether unworthy of credit. But while this class of writers has seemed anxious to reduce man to the station of the apes, another has endeavoured to prove that there are some of the monkey tribe who are habitually biped. The allusions already made to the structure of their skeleton (which has been most fully illustrated by Mr. Owen in the 'Zool. Trans.' vol. i.) will have rendered this extremely improbable; and it is now perfectly certain, from repeated observation, that the gesture of even those orangs who are most man-like is never agile or easy unless they employ all their limbs to support them. The attempts of other animals, as dogs, bears, &c., who are taught to assume the erect posture, are even more constrained than those of the monkeys.

Man alone is two-handed. 'That,' says Cuvier (*Regne Animal*, i. 78), 'which constitutes the *hand*, properly so called, is the faculty of opposing the thumb to the other fingers to seize the most minute objects, a faculty which is carried to its highest degree of perfection in man, in whom the whole anterior extremity is free, and can be employed in prehension.' Hands thus defined occur only in man and in monkeys; the former is therefore made to constitute a separate order, 'Bimanous,' and the latter are included in a second order, as quadrumanous, or four-handed.

Although formed on the same general plan as the anterior extremity of all vertebrated animals, the structure of the human hand is so much more complicated than theirs, and adapted to so many more intricate offices, that Sir C. Bell (*Bridgewater Treatise*, p. 18) has said, 'We ought to define the hand as belonging exclusively to man.' Its perfection as an organ of prehension is due partly to its own construction, and partly to the form of the parts with which it is connected, for 'the whole frame must conform to the hand, and act with reference to it.' The erect attitude, for example, which has been proved to be that which is natural to man, is necessary to its full action, and to that wide range of motion which it receives from the arm, and which is the main object in the construction of all the parts by which the hand is connected with the trunk. And in like manner it could be proved that more remotely the peculiarities of the organs of sensation, of digestion, and of other functions are adapted to the hands.

By a powerful collar-bone, which keeps the shoulder and arm apart from the chest, man obtains, in common with all the animals which have much power in digging, flying, or climbing, as moles, bats, squirrels, &c., a powerful lateral and inward motion of the arm, and a wider range for action beyond the body. His scapula, or shoulder-bone, is strong and broad, and has a prominent spine and acromion, to which muscles are attached, while its glenoid cavity, being directed outwards, and maintained there by the clavicle, leaves all the outward motions of the arm perfectly free from hindrance. In the same degree the hemispherical head of the humerus loosely adapted to the shallow glenoid cavity, its long and light shaft, and its flattened tuberosities, all combine to produce a freedom of motion in the upper arm, which, were it used as an organ of support, could not exist without danger of injury, but which are essential to the wide range within which it is necessary that the hand should act. The only motions of the fore-arm upon the upper arm are those of flexion and extension; by the former the hand can be brought within, and by the latter carried beyond the range of motion of which the upper arm alone is capable. The bones of the fore-arm itself are so articulated that one may rotate on the other in any position of the arm; the bone, which in this rotation is fixed, being that by which the hinge-joint of the elbow is formed, while that which rolls over it is articulated by another hinge-joint with the wrist and hand. Thus then were the hand itself powerless, there would be in the other bones and joints of the upper extremity provisions for moving it through the greater part of a sphere whose radius is equal to the length of the arm, for bringing it to any point in that sphere, and for moving it in any direction at that point.

The perfection of the structure of the hand itself is chiefly due to the size and strength of the thumb, by which its superiority over the hands of monkeys (who enjoy a freedom of motion of the arm equal to that which man possesses) is also chiefly produced. From its size and strength the thumb of the human hand can be brought into exact and powerful opposition to the extremities of the fingers, which are all moreover separately moveable, and can each in its turn, or altogether, be employed in association with the thumb. The least consideration will show how numerous are the actions in which this easy and exact opposition of the tips of the thumb and of one or more fingers, if not necessary, is at least essential to dexterity. In those monkeys which approach most nearly to man the thumb is so short and weak, and the fingers so long and slender, that their tips can scarcely be brought in opposition, and can never be opposed in near contact with each other with any degree of force. Hence though admirably adapted for clinging round bodies of a certain size, as the small branches of trees, &c., they can neither seize very minute objects, nor support large ones; but the hand of man is adapted for all these and many other purposes.

It is a great peculiarity of man that his hands and feet are so different from each other; and in man alone their uses are totally different. In the monkeys all the extremities are alike formed to be organs of prehension; in the carnivora all are alike organs of progression and support; in the hoofed animals all are organs of support alone; in man the anterior or upper extremities are entirely for prehension, the posterior, or lower, entirely for support. M. Bory de St. Vincent (art. 'Orang,' *Dict. Cl. d'Hist. Nat.*) indeed thinks that the absence of a prehensile power in the human foot is uncertain, and that the position of the great toe may be changed so as to convert the foot of man into a hand, like that of the monkey. He says there are peasants in the Landes of Aquitaine who are termed *resiniers*, from collecting the resin of the *Pinus maritima*, who acquire a power of opposing the great toe to the others, like a thumb; but it would surely be as incorrect to deduce from the instances of rarely acquired power in these peasants, or in those who are born without hands, and can write or work with their toes, that the human foot is naturally an organ of prehension, as it would to assume that the natural position of the bear is erect, because a few of his species have been taught to maintain such a position for a short time. Besides, in those who have been born without hands, and have endeavoured to substitute their feet, the prehension of small bodies has been effected not by opposing the great toe to the others, but by flexing its phalanges firmly against its ball.

With one exception (in the fossil genus Anoplotherium) man is distinguished from all other animals by the equality in length of all his teeth, and by the equally close approximation of them all in each jaw. Even the most anthropomorphous apes (as the chimpanzee and orang-outan) have the canine teeth longer than the others, and an interval in the line of teeth in each side of each jaw, to receive the canine teeth of the opposite jaw. The vertical position of the human teeth, on which one of the most characteristic features of the human face, the prominent chin, depends, is also quite peculiar, and is intimately connected both with his erect attitude and with the perfection of his hands, by which the divided food is conveyed to the mouth. The intermaxillary bones in which the upper incisor teeth are developed, have often been described as absent in man alone; but in fact they are only united to the upper maxillary bones at a very early period of the life of the human foetus. The extent of the palatine portions of these bones is indicated by the position of the foramina incisiva, which in man are united into one hole, which is much nearer to the incisor teeth than in any quadrumanous animal.

The smoothness of his skin and the entire deficiency of all natural arms either of attack or of defence are other peculiarities of the human race. The face and body of the most delicate female are indeed covered with hair, and therefore man must be regarded as a hairy animal; but there is sufficient difference between the fine colourless and downy hair with which the human body generally is beset, and the long silky or woolly hair with which even the quadrumanous apes are covered, to adopt this as an additional specific character of mankind. Some parts of the human body, on the other hand, are even more hairy than those of other animals, as the scalp, axillæ, &c. In his naturally unarmed condition, destitute of either projecting teeth or strong claws, covered neither with hard scales, nor with bristles, nor with a thick hide, and surpassed in speed by many of his more powerful antagonists, man's condition would seem most pitiable, and inferior to that of any other animal: for on all the rest of those to whom she has denied the weapons of attack, nature has bestowed the means either of defence, or of concealment, or of flight. But man, by his superior reason, has subdued all other animals. His intellect can scarcely suggest the mechanism which his hands cannot frame; and he has made for himself arms more powerful and destructive than any other creature wields; he has clothed himself in armour and built walls of defence with which he can defy the attacks of any but his fellow-men. Naturally unarmed, man has conquered the whole armed creation; some he has driven from their abodes, and almost exterminated; others he has forced to share his labour; and others he uses for his food, his clothing, or his pleasure.

The only other part of the human structure which it is now necessary to notice is the brain, whose size in proportion to the rest of the nervous system far surpasses that of any other animal. This may be at once seen by observing the proportion which the cranium, or rather the cavity containing the brain, and the face, bear to each other. In many cases also it may be estimated by what is called the facial angle of Camper, which is found by drawing a line from the most prominent part of the forehead to that of the upper jaw-bone, and observing the angle which it forms with another line drawn through the meatus auditorius externus to the base of the nose, or (the head being held in a vertical position) with a horizontal line. In man the facial angle is in the average of Europeans 80°; in some children it is a right angle, but in some negroes it is not more than 70°. In the adult chimpanzee (which approaches in this respect nearest to man) the facial angle is only 35°, and in the orang or satyr 30°. (Owen,* in *Zool. Trans.*) In other animals it is still less, except when it is increased by the prominence of large frontal sinuses, or by the comparative shortness of the jaws. In regard to its structure the human brain exceeds all others in the development of its cerebral hemispheres, in the number and development of parts, in the depth and number of its convolutions, and in the quantity of its medullary matter in proportion to the cortical.

In the economy of the human body there are peculiarities not less marked than those in its structure. Perhaps the most characteristic is the ability which man enjoys of living on almost any part of the globe, and of thriving alike in either extreme of natural temperature. Thus the Greenlanders and Esquimaux have reached between 70° and 80° of north latitude, while the negro of Africa and the red man of America live under the equator. But even Europeans, accustomed to a temperate climate, can bear either of these extremes of cold and heat, as has been sufficiently proved by the numerous instances in which those who have gone on the Arctic expeditions have been obliged to winter in high northern latitudes; and on the other hand by the slight degree in which European settlers in the hottest parts of Africa are influenced by the temperature.

Man subsists with equal facility under various degrees of atmospheric pressure. The valleys, and the elevated table-lands of South America, some of which are 10,000 feet high, are both inhabited by man, the barometer standing in the one at 30, and in the other at only 20 inches. Condamine and Bouguer, with their attendants, lived for three weeks at a height of 14,000 French feet above the level of the sea, where the barometer stood at 14¾ inches, and the atmospheric pressure was therefore only a little more than half that to which they had been accustomed.

In adaptation with his ability to inhabit almost every climate, man can subsist on the most varied food. In the northern regions, where the earth is covered through the greater part of the year with snow, and vegetables of any kind can be procured only in the smallest quantity, the Esquimaux and Kamtschatdales subsist as well on animal food alone as the European does on the most carefully mixed diet;† and on the other hand the inhabitant of the torrid zone is not more inconvenienced by his daily subsistence on the cocoa-nut, banana, yam, rice, and other farinaceous and acid vegetables. In the temperate climates, where animal and vegetable food can be procured with equal facility, man is truly omnivorous; towards the poles animal food or fish becomes more exclusively his diet; and towards the equator his food is chiefly composed of vegetables; and there is no doubt that in each case that food which is most universally adopted is that which is best adapted for the health of the inhabitants.

Thus then, in his comparatively complete independence of the variations of external circumstances, man stands alone. It is singular that the animals who approach most nearly to him in structure should be amongst those who, in this respect of geographical distribution, differ most widely from him. The chimpanzee and orang-outan, for example, are confined to the islands of Borneo and Sumatra, the coasts of Guinea, and a few other parts of Africa; and even in their native countries they occur in but small numbers. The difficulty too of removing them to colder climates, and of preserving their lives there, even with all the advantages which human art can suggest, is immense, and after a few months they become diseased and die. Hence we may conclude that although he receives much aid in supporting the extremes of climate from the various means of defence with which his arts have supplied him, there is yet a strength and pliancy of frame in man which peculiarly fit him, and him alone, for universal distribution over the surface of the earth.

---

* Mr. Owen has shown that the measurements which appeared to prove a greater proportionate development of the brain in these animals were made on the skulls of young individuals.

† The white men who hunt the beaver and trade for buffalo in the regions of the Upper Missouri and the Columbia river, often live for many months on the flesh of animals only.

Man is further remarkable for his slow growth, and for the length of time during which he remains in a state of helpless infancy and of youth. The process of ossification and the closure of the sutures of the skull are completed later in him than in any other animal; he is unable to seek his own food for at least the three first years of his life, and does not attain to the adult period or to his full stature till he is from fifteen to twenty years old. The length of time to which his life may be prolonged is however proportionally greater than that of any animal, and is especially interesting when compared with that of those who in many respects resemble him. The greatest longevity to which the orangs attain is about thirty years, while in all nations of men instances occur of life being prolonged to upwards of 100 years.

However widely man may be distinguished from other animals in the peculiarities of his structure and economy already detailed, yet we must agree with Dr. Prichard (*Researches*, *&c.*, i. 175) that 'The sentiments, feelings, sympathies, internal consciousness, and mind, and the habitudes of life and action thence resulting, are the real and essential characteristics of humanity.' The difference in these respects between man and all other animals is indeed so great, that a comparison is scarcely possible. The highest moral endowments of animals are shown in their attachment to their offspring; but this ceases when the period of helplessness is past, and there is no evidence of attachment between individuals, except in the associated labours of some species, and the consentaneous actions of the male and female for the safety of the offspring. The arts of which animals are capable are limited and peculiar to each species; and there seems to be no evidence of a power of invention, or of construction for any purpose beyond that to which the original and instinctive powers are adapted. Among the monkeys the adults exercise authority over the young, and, it is said, maintain it even by chastisement; but there is no instance in which the stronger species has exercised authority over the weaker, or brought it into a state of servitude. Even when made the associates of man, and instructed by him, how little have animals learned: a few unmeaning tricks unwillingly performed, a few words uttered and constantly repeated, without choice or a conception of their meaning, and sullen passive submission, are in general the best results that can be found. There is not a proof in the whole history of animals that any species or individual has ever made an advance towards an improvement, or an alteration in its condition; whether solitary or living in herds, the habits of all remain the same; all of the same species appear endowed with the same faculties and dispositions, and each is in mental power the same throughout his life.

Contrast with these the progress of man. In his origin weak, naked, and defenceless, he has not only obtained dominion over all the animate creation, but the very elements are made to serve his purpose. Of the earth he has built his houses, and constructed weapons and the implements of art; he uses the wind to carry him in ships, and to prepare his food; and when the wind will not suit him, he employs fire and water to replace or to resist it. By artificial light he has prevented the inconveniences of darkness; he has stopped and made rivers, and has forced deserts, marshes, and forests alike to bear his food; he has marked out and measured the course of the celestial bodies, till he has discovered from them the size and form of the earth that he himself inhabits.

In intimate connection with his exalted mental endowments is man's peculiar possession of language. Other animals are naturally speechless, not from any material difference in the form of their organs (for man can teach some of them to imitate him), but from their inability to form those associations of ideas which are essential to the construction and utterance of words.

The peculiarities above described will probably be deemed sufficient to justify the separation of man as a distinct species from all others in the animal kingdom. In these respects indeed the difference between the lowest man and any animal is far greater than the change which any species can be proved or supposed to have undergone in any period of time, and under however varied circumstances; so that if degrees of difference of this kind could be measured, there would probably be as much justice as convenience in the classifications of those naturalists who have separated man from other animals to the greatest possible distance by constituting of the single species a separate genus and order.

We come now to the consideration of the variations to which the general characteristics of the human race are subject.

Varieties in form are of course chiefly referrible to differences in the structure and proportion of the parts of the skeleton, and we find the most marked characters of the different races in the varied forms of the skull. Dr. Prichard (*Researches*, i., 281) refers the varieties in the form of the skull to three principal divisions:—1st. The symmetrical or oval form, in which are included all those of the Indo-Atlantic, or Iranian nations, comprising the countries from the Himalaya mountains to the Indian Ocean, including the whole of Hindustan and the Deccan, as well as Persia and Arabia; and from the Ganges to the borders of the Atlantic, including the north of Africa and nearly the whole of Europe. In this variety the head is rounder than in the others, the forehead is more expanded, and the upper jaw-bones and zygomatic arches are so formed as to give the face an oval shape, while it is nearly on a plane with the forehead and cheek-bones, and does not project towards the lower part. The cheek-bones neither project outwards and laterally, nor forwards. The alveolar process of the upper jaw is well rounded and slightly curved vertically, so that the teeth are almost exactly perpendicular. 2nd. The narrow and elongated, or prognathous skull, which is found in the Negroes, the Papuas, Alfourous, New Zealanders, Australians, and other neighbouring oceanic nations, and of which the most marked specimens occur in the negroes of the Gold Coast. The chief character of these skulls is that they give the idea of lateral compression and elongation. The cheek-bones project forward and not outward. The upper jaw is lengthened and projects forwards, giving to the alveolar ridge and the teeth a similar projection, and thus diminishing the facial angle. 3rd. The broad and square-faced, or pyramidal skull, which is that of the Turanian, or northern Asiatic nations, Samoiedes, Yukagers, Koriacs, Tschuktschi, Kamtchadales, Tungusians, Chinese, Indo-Chinese, Tangutians and Japanese, part of the Tartar race, and of the Finnish nations of Europe, the Esquimaux, the aboriginal Americans, and the Hottentots. The Mongols afford a good specimen of this form, and the Esquimaux an exaggerated one. Its most striking character is the lateral or outward projection of the zygomata, so that lines drawn from each, touching the sides of the frontal bone, will meet only a little above the apex of the forehead. The cheek-bones project from under the middle of the orbit, and turn backwards in a large arch or segment of a circle. The orbits are large and deep; the upper part of the face remarkably plane and flat; and the nasal-bones, as well as the space between the eyebrows, nearly on the same plane with the cheek-bones.

The varieties of features dependent on the differences in the form of the frame-work just described will be at once evident. The first variety is distinguished by an evenness and regularity of features, an absence of any excessive prominence of one part in proportion to the other, a smooth and gently-rounded cheek, compressed and small lips, a full and prominent chin, and the whole face of a tolerably regular oval form. It is probable that among European nations the Greeks have displayed the greatest perfection in the form of the head, at least according to the European standard of perfection. Blumenbach has described a Greek skull in his collection, which, in the beauty of its form, agrees perfectly with the finest works of Grecian sculpture, and renders it probable that the latter were actual copies of nature, and not, as some have supposed, ideal compositions, intended to give the expression of exalted intellect or of dignity. The same author describes also the skull of a Georgian woman, equally remarkable for its elegance and symmetry, and says that its form agrees exactly with that of the head of a marble statue of a nymph in the Townley Collection.

The features corresponding with the narrow elongated skull are distinguished by the prominence of the jaws, from which they acquire a peculiarly ferocious and ani-

and character. The compressed, narrow, and retreating forehead; the scarcely prominent nose, with its wide expanded nostrils; the thick projecting lips and the retreating chin; the projecting cheeks, and the heavy jaws, combine to add to the characters which approximate, though they do not identify, the form of the negro with that of animals.

The features of the third variety differ scarcely less from the European than those of the negro, but in a different direction. Instead of the long and prominent face, we here find a face which is broadest transversely from one cheek-bone to the other, and which, as it gradually narrows both above and below, acquires somewhat of a lozenge shape. The nose is flat, the space between the eyes generally depressed, and the eyes themselves most frequently placed obliquely, with their internal angles descending towards the nose, rounded and open; the lips large, but not so prominent as those of the negro; the chin short, but not retreating under the lips.

But these varieties are not separated by very definite limits. There are numerous instances of negroes remarkable for the beauty and European character of their features; and daily observation shows Europeans who, in the narrowness of the skull, the lowness of the forehead, and the prominence of the jaws, closely approximate to the negro; while others in their features resemble the broad and flat-faced Tartars or Chinese. Within each of these varieties moreover are included numerous smaller divisions, which are certainly, though less prominently, distinct in their features. The varieties of national appearance between the Scotch, English, French, and Germans, for example, are in general distinguishable, though it would be difficult to define their differences. Similar subdivisions of character exist among all the varieties, and so fill up the intervals between the extreme specimens of each as to form a regular and nearly perfect series, of which the Esquimaux and negro might occupy the extremities, and the European the middle place, between the broad and high features of the one, and the narrow, elongated, and depressed skull and face of the other.

Differences in the shape of the pelvis (on which depend some important differences in the external form of the body) have been often supposed characteristic of different races of men. But from an extended series of observations by Professor Weber, it has been lately shown that every form of the pelvis which deviates from the ordinary type, in whatever race it may most frequently occur, finds its analogues in other races. He has arranged the various shapes of the human pelvis in four classes, the oval, the round, the square, and the cuneiform or oblong; and he shows that although the first is the most general form in Europeans, the second in the Americans, the third in the Mongolians, and the last in the Africans, yet that specimens of each kind may be found in all the different races.

The chest of the negro is somewhat more expanded than that of the European, the sternum more arched, the ribs larger and more roundly curved. In general also the negro's fore-arm, measured in proportion to his upper arm and to the height of the body, is longer than in the European. The knees of negroes often appear to Europeans knock-kneed, the bones of the leg bending out from beneath them, and the feet turned outwards in the manner commonly called splay-footed. The tibia and fibula also are rather more convex than in Europeans; the feet are flat, and the os calcis, instead of being arched, is nearly in a straight line with the rest of the tarsus; and the gastrocnemius muscles have the greater part of their mass high up in the leg, so that the calves seem to encroach upon the knees. The hands are generally narrow, the fingers long and very flexible.

It is from these modifications which the negro presents, and taking extreme cases of each peculiarity, that there has appeared some ground for supposing the negro to form a grade intermediate between the European and the monkey. But there is no character in which the difference between the lowest negro and the highest ape is not many times greater than that between the same negro and the highest European; and in all the important points of structure which we have already mentioned the differences which the negro presents are but slight. The length of the base of the skull, the somewhat more backward situation of the foramen magnum, the decrease of the facial angle, and the projection of the teeth, depend almost entirely on the prominence of the alveolar process of the upper jaw; and if a slight allowance be made for it, the negro in these points resembles the European. So also in the prominency of his two ossa nasi, the position of the cranium over the greater part of the face, the equal length and approximation of all his teeth, the full development of the mastoid and styloid processes, which are nearly or quite wanting in all apes, and numerous other essential characteristics, there is no difference between the two races. At the same time therefore that it is allowed that the characters of form which the lowest class of negroes presents are more like those of the monkey than those of the European are, it is certain that the approximation is but slight, and that a vast space is still left between them. It is true that there coincides with this degradation of form a very low degree of intellectual development; but it is not lower than that of the Esquimaux and Hottentots and many of the third variety, who in some respects, as the breadth of the skull and face, are even more distantly removed from the monkeys than Europeans are.

Considerable differences occur in the general stature of the several races of mankind. In the temperate climates of Europe the general height varies from 5½ to 6 feet; the instances in which individuals have fallen far short or have much exceeded this standard are too exceptional to be taken into a general account. [DWARF; GIANT.] Among the native inhabitants of America great varieties occur. The Peruvians, the natives of Tierra del Fuego and of Nootka Sound, the Esquimaux, and the Chaymas are all described as very diminutive; while the Payaguas, Caribees, Cherokees, and the natives of the regions immediately north of Canada are said to be generally much above the standard of Europeans. The height of the Patagonians also, though often exaggerated, is yet remarkable; the most authentic accounts agree that they commonly attain the height of six feet, and that they not unfrequently surpass it. The standard of height among the Africans appears about the same as that of Europeans. The Hottentots are below the general size, and the Bushmen still more so, for among them 4½ feet is said to be the average height of the men, and 4 feet that of the women. The Caffres on the contrary, the neighbouring tribe to the Hottentots, are distinguished for their height and strength. The people of the north of Asia and the Laplanders and Samoiedes in Europe are generally shorter than the inhabitants of the warmer climates; but the Chinese and Japanese, who in other respects much resemble them, are of about the same stature as the rest of the Europeans.

With these varieties in stature it is interesting to compare the amounts of physical power possessed by different nations. The result of all observation has been the exact contrary of popular belief, which ascribes a decrease of physical strength proportionate to the increase of intellectual power acquired by civilization. The Spaniards in their first intercourse with America found the natives in general much weaker than themselves; and the inability of the natives to sustain the severe labour of the mines led to the introduction of African slaves, one of whom was equal to three or four Indians. Hearne and others have found the same feebleness in the natives of various parts of the North American continent, and Pallas in the Burats. But the most exact observations were made by Péron with the dynamometer upon 12 natives of Van Diemen's Land, 17 of New Holland, 56 of the Island of Timor, 17 Frenchmen belonging to the expedition, and 14 Englishmen in the colony of New South Wales. The mean results were as follows:—

	Strength of the Arms. Kilogrammes.	Strength of the Loins. Myriagrammes.
Van Diemen's Land . .	50·6	—
New Holland	50·8	10·2
Timor	58·7	11·6
France	69·2	15·2
England	71·4	16·2

The substance on which the varieties of colour in the human race depend, is seated chiefly in the soft and more internal layers of the cuticle; the true skin (cutis, dermis) is similar in all nations, and the outer hardened layers of the cuticle have only a light tinge of the colour of those beneath them, which constitute what is often called the rete mucosum. [CUTICLE; SKIN.] The human complexion depends in part on the condition of the cutis and its vessels, and in part on that of the cuticle. In white nations, according to the fulness or comparative emptiness of the blood vessels of the skin, we find all the gradations of complexion, from the deep ruddiness of full health, to the blanched pallor of sickness; and in negroes, the same changes are indicated by a greater intensity of the blackness and by a dull leaden hue. These differences however chiefly characterise individuals; the national variations depend rather on the cuticle. A thick and opaque though colourless cuticle, obscuring the blood of the cutis, assists greatly in giving that deadness of hue and phlegmatic aspect which distinguishes some Europeans from others who with a thinner and more translucent epidermis are marked by a florid ruddy complexion. As the cuticle becomes darker in colour, it obscures more completely the colour of the blood in the subjacent tissue, and hence it is only in nations of light complexion that sudden blushing or paleness is at once perceptible.

With the varieties in the colour of the skin there generally coincide analogous differences in the hair and eyes. It is probable indeed that the colouring matter is the same in all; being combined in the cuticle with its peculiar cells and scales, in the hair with a horny substance, and in the choroid membrane and uvea with their minute roundish particles.

Dr. Prichard refers all the differences of complexion in man to three principal varieties:—1. The Melanocomous, or black-haired, which is the complexion generally prevalent, except in the northern parts of Europe and Asia. The coincident colour of the skin varies from a deep black, as in some Africans, to a much lighter or more dilute shade. In the copper-coloured nations of America and Africa the dusky hue is combined with red, while in the olive-coloured races of Asia it is mixed with a tinge of yellow. In intensity of colour there is every shade from the black of the Senegal negro to the light olive of the northern Hindus, and from the latter there may be traced every variety of shade among the Persians and other Asiatics, to the complexion of the swarthy Spaniards, and of black-haired Europeans in general. 2. The Leucous, or Albino variety, examples of which occur in all countries [ALBINO], but perhaps most frequently in hot climates. They are distinguished by the total absence of the colouring matter of the cuticle, hair, and eyes; hence their skin is of a milk-white or pinkish-hue, the hair silky-white or at most yellowish, the iris rosy and the pupil intensely red. 3. The Xanthous, or yellow-haired variety, which includes all those individuals who have light-brown, auburn, yellow, or red hair. Their general complexion is fair, acquiring on exposure to heat and light not a brown hue, but more or less of a red tint. The eyes are light coloured. This is the variety most prevalent in the temperately cold regions of Europe and Asia, whose climate seems peculiarly favourable to the constitution of body connected with it. This variety may spring up in any black-haired tribe; as it has in the Jews, who, though generally black haired, present many examples of the light fair complexion and reddish hair. Dr. Prichard also adduces (*Researches*, &c., i. 228) ample evidence that instances of this variety occur not only among the Greeks, Romans, Russians, Laplanders, Tartars, and other Melanocomous races of the least swarthy shade, but among the Egyptians, African negroes, and the islanders of the Pacific. The majority of these last cases have been confounded, under the term of white negroes, with the real Albinos; but they differ from them in the more ruddy hue of the skin, the colour of the iris, the blackness of the pupil, and the flaxen or red colour of the hair.

Other varieties besides those of colour occur in the skin and its appendages. The skin of many tribes of negroes is peculiarly sleek and oily, from the abundance of sebaceous and perspiratory secretion. From many also there is emitted a peculiarly strong odour, and Humboldt says that the Peruvians can by the sense of smell alone distinguish the European, the American Indian, and the negro. The cuticle of the dark tribes is thicker and coarser than that of white nations, and, from the greater difficulty of separating the latter into two layers, it has been imagined that there is no rete mucosum, or soft cuticle, in Europeans. The hair also varies almost as much in its texture as in its colour. Its chief varieties are observed in the copious, long, soft, and more or less curly hair of various colours in the European; the strong, straight, and scanty hair of the South Sea islanders; and the black, fine, wiry, crisp hair of the negro. A very general characteristic of the darker-coloured nations is either an entire want of beard, or a very scanty one developed later in life than in the white races. Mr. Lawrence (*Lectures*, 272) has adduced proofs of this in the Mongols, the Chinese, Japanese, Malays, South Sea Islanders, negroes, and the Indians of North and South America; but the fact has been somewhat obscured by the practice, which is generally prevalent among these nations, of extirpating the little hair which they have.

In the performance of the several functions of the economy, it has not yet appeared that any fixed difference exists in the several races of men, except in cases in which the variation is due to the difference of climate, and occurs alike in all races when subjected to the same influence. In physical endowments also, however great may be the distance between the degrees of intellectual and moral elevation possessed by civilised and uncivilised nations, yet there is sufficient evidence to prove that in all there may be traced the same mental endowments, similar natural prejudices and impressions, the same consciousness, sentiments, sympathies, propensities, in short a common physical nature, or a common mind. (See Prichard's *Researches.*)

This accordance in the physiological and psychical properties of all nations affords one of the strongest possible arguments in favour of the whole human race being but one species; for, as Dr. Prichard observes, 'the physiological characters of race are liable to few and unimportant variations;' and therefore when we find that in the number of individuals spread over the greater part of the globe no other differences occur, either in the average length of life, or the extreme length occasionally attained, in the periods of gestation, of infancy, of puberty, and of other changes in the economy, or in the habits, instincts, affections, and intellectual faculties, than may be fairly attributed to the differences of external circumstances, it may be at once concluded that they are all members of the same family, and the offspring of one common stock. This argument receives support from the fact that in many animals which from their forms alone it might be difficult to determine whether they belonged to the same or different species, a diversity occurs in their physiological characters. Thus the wolf and dog, though in many other respects closely resembling each other, differ in the period of gestation, the she-wolf carrying her young ninety days, and the bitch (of whatever variety) only sixty-two or sixty-three. In like manner the dog is strongly distinguished from the wolf in his inclination, which is everywhere observable, to associate with man; and the fox from both the wolf and dog, in his solitary habits. Yet in form these three agree so nearly, that some naturalists have deemed them to be the same species. Similar differences may be observed in the ox kind, between the domestic ox and the bison and buffalo, which, though nearly resembling him in form, are totally opposite in disposition and habits. So also the most marked differences between the sheep (in all its varieties) and the goat are to be found in their instincts and consequent modes of life; and so on through numberless other instances, all tending to prove the permanence of physiological and psychical characters in each species, and their comparative independence of those influences by which modifications in form and colour are produced.

It is necessary however to show that the structural differences which seem to distinguish so clearly the several nations of mankind coincide with similar variations in animals which are descended from a common stock. Such variations occur especially in animals which have been domesticated, and thus subjected to influences in many respects analogous to those under which man has fallen in the progress or decline of civilization. No one, for example, will be inclined to deny that the varieties of dogs (which there is reason to believe are all of one species) present far greater differences in form and colour, and in many parts of their habits and instincts, than any that are observed in man. And it is worthy of observation that in the highly domesticated races, as the spaniel, the cranium is more fully developed, and recedes further from the form of the skull proper to the wolf, than in those which are less cultivated, as the mastiff. In this we can trace a series of varieties very analogous to those of the monkey, the negro, and the highly civilised European.

The races of swine present even more remarkable instances of variation, which have been particularly described by Blumenbach (*Beyträge zur Naturgesch.*). It is certain that these all descend from the wild boar; and it is equally certain that swine were unknown in America till carried duced by the Spaniards. Yet in that country they have already degenerated into breeds very different from each other and from their original. Those taken to Cubagua became a race with tusks half a span long, and those of Cuba became more than twice as large as their progenitors. In Normandy the swine are remarkable for the length of the bones of the hind leg. Swine with solid hoofs were known to the ancients, and large breeds of them are found in Hungary and Sweden. In some also the hoof is divided into five clefts. In Guinea they have long ears couched upon the back; in China, a large pendent belly and very short legs; at Cape Verd and other places, very large curved tusks. Thus then in one species we find changes even greater than those which occur among men; and as to the most important, Blumenbach says that the whole difference between the cranium of the negro and that of a European is by no means greater than that which exists between the cranium of the wild boar and that of the domestic swine. An examination of the different breeds of sheep, horses, oxen, goats, cats, rabbits, and still more of domestic fowl, would in like manner show that all these species, even while under observation, are subject to greater variations than are found in the different races of men.

In respect of colour, a perfect analogy holds between the varieties of domestic animals and those of men. In all those enumerated above, examples occur of the melanous, leucous, and xanthous varieties springing up casually or existing constantly in particular breeds. Thus even in England the cattle of different counties may be recognised by their colour as well as their forms. Azara remarks of the horses and oxen of Paraguay (where both species have run wild and multiplied very rapidly) that while all those that are domesticated vary considerably in colour, those that are wild have all the same colour; the horses a chesnut or bay brown, the oxen reddish brown on the back and black on the rest of the body.

The analogy between the variations to which domesticated (and many newly wild) animals are subject, and those which are observed in men, is a strong argument for the unity of the human species. Another which deserves much weight is drawn from the propagation of the several races. It is well known that among all other animals the hybrid productions of parents of different species are either quite barren or so little prolific that they soon become extinct, and that an intermediate race cannot be maintained even to the second generation without a return to the pure blood of one or other parent. On the other hand it is observed among domestic animals that the progeny of different varieties of the same species exceed in vigour, and are even more prolific than their parents; so that intermediate races are apt very soon to become more numerous than the originals from which they sprung. Exactly the same principle holds in the human race. All nations propagate together with equal facility, and Dr. Prichard has shown that the progeny of parents of different nations have in many instances exceeded those from whom they sprung in vigour and in the tendency to multiplication.

Lastly, a consideration of the diseases to which mankind are subject shows that the greater part of them are common to all, though modified in different climates, and though a few produced by local circumstances are peculiar to individual tribes.

From these facts therefore, by which it is shown that in all those characters in which external circumstances have least influence the whole human race agrees, while in others more easily modified they present only those changes which are observed to an equal or even a greater extent in animals known to have descended from a common stock, it may fairly be concluded that mankind is composed of but one species. The characters of this species given by Blumenbach, and generally received, are: 'Erect, two-handed, unarmed, rational, endowed with speech; a prominent chin; four incisor teeth above and below; all the teeth equally approximated; the canine teeth of the same length as the others; the lower incisors erect.' The same author divides the species into five varieties, whose characters are as follows (Lawrence, *Lectures*, p. 477):—1. Caucasian variety: a white skin, either with a fair rosy tint, or inclining to brown; red cheeks; hair black, or of the various lighter colours, copious, soft, and generally curled or waving. Irides dark in those with brown skin; light in the fair or rosy complexioned. Large cranium with small face; the upper and anterior regions of the former particularly developed, and the latter falling perpendicularly under them. Face oval and straight, with distinct features; expanded forehead; narrow and rather aquiline nose, and small mouth; front teeth of both jaws perpendicular; lips, particularly the lower, gently turned out; chin full and rounded. Moral feelings and intellectual powers most energetic, and susceptible of the highest development and culture. This variety includes all the ancient and modern Europeans except the Finns; the former and present inhabitants of Western Asia, as far as the River Oby, the Caspian Sea, and the Ganges (that is, the Assyrians, Medes, and Chaldeans; the Sarmatians, Scythians, and Parthians; the Philistines, Phœnicians, Jews, and the inhabitants of Syria generally; the Tartars, properly so called; the tribes actually occupying the chain of Caucasus; the Georgians, Circassians, Mingrelians, Armenians; the Turks, Persians, Arabians, Afghans, and Hindus of high castes); and the northern Africans, the Egyptians, Abyssinians, and Guanches.

2. The Mongolian variety:—characterised by olive colour, which in many cases is very light, and black eyes; black, straight, strong, and thin hair; little or no beard; head of a square form, with small and low forehead; broad and flattened face, with the features running together; the glabella flat and very broad; nose small and flat; rounded cheeks, projecting externally; narrow and linear aperture of the eye-lids; eyes placed very obliquely; slight projection of the chin; large ears; thick lips; stature, particularly in the countries near the north pole, inferior to that of Europeans. It includes the tribes of Central and Northern Asia, as the Mongols, Calmucks, and Buriats; the Mantchous, Daourians, Tungooses, and Coreans; the Samoiedes, Yukagers, Koriaks, Tschuktschi, and Kamtschatdales; the Chinese and Japanese, the inhabitants of Tibet and Boutan, of Tonquin, Cochin-China, Ava, Pegu, Cambodia, Laos, and Siam; the Finnish races of Northern Europe, as the Laplanders and the tribes of Esquimaux.

3. The Ethiopian variety:—skin and eyes black; hair black and woolly; skull compressed laterally and elongated towards the front; forehead low, narrow, and slanting; cheek-bones prominent; jaws narrow and projecting; upper front teeth oblique; chin receding. The eyes prominent; the nose broad, thick, flat, and confused with the extended jaw; the lips, and particularly the upper one, thick. All the natives of Africa, not included in the first variety, belong to this.

4. The American variety:—skin dark, and more or less of a red tint; black, straight, and strong hair; small beard; and a countenance and skull very similar to the Mongolian. The forehead low, the eyes deep, the face broad, particularly across the cheeks, but not so flattened as in the Mongols. Mouth large; and lips rather thick. This variety includes all the native Americans except the Esquimaux.

5. The Malay variety:—brown colour, from a light tawny to a deep brown. Hair black, more or less curled, and abundant; head rather narrow; bones of the face large and prominent; nose full, and broad towards the apex; mouth large. In this are included the inhabitants of Malacca, of Sumatra, Java, Borneo, Celebes, and the adjacent Asiatic Islands; of the Molucca, Ladrone, Philippine, Marian, and Caroline groups; of New Holland, Van Diemen's Land, New Guinea, New Zealand, and of all the islands of the South Sea.

Cuvier distinguishes only three principal divisions—the Caucasian, the Mongolian, and the Ethiopian; remaining doubtful as to the Malay and American varieties. Dr. Prichard on the other hand (and his authority should have the greatest weight in everything relating to the subject) divides the species into seven principal varieties:—1. The Iranians, who in the form of their skulls and other physical characters resemble Europeans, in which are included, as before detailed, all the Caucasian variety. 2. The Turanians, who are nearly the same with the Mongolians of other writers. 3. The native Americans, except the Esquimaux and some others resembling them. 4. The Hottentots and Bushmen. 5. The Negroes. 6. The Papuas, or woolly-haired nations of Polynesia. 7. The Alfourou and Australian races.

MAN, ISLE OF, is situated between 54° 3' and 54° 27' N. lat., and 4° 17' and 4° 53' W. long.; 24 miles from St. Bees' Head in Cumberland; 16 from Burrow Head in Scotland, and 28 from Strangford, in Ireland. Its length, from north-north-east to south-south-west, is about 30 miles; its breadth varies from about 8 to 11 miles, but is much narrower at its extremities; and its circumference is about 75 miles. Its surface is about 220 square miles. The Calf of Man is a small island situated to the south-west of the island, nearly a mile from it, and from 3 to 5 miles in circumference. The Kitterlins, another small rocky island, is situated between the Isle and Calf of Man. The Isle of Man is the Mona of Cæsar, the Monapia of Pliny, Monæda of Ptolemy, Menavia of Orosius and Bede, and Eubonia of Nennius. Its derivation is probably from the British word 'mon,' which means isolated.

The island is intersected by a ridge of mountains, which runs from north-east to south-west nearly through its whole length, and chiefly occupies the central parts. Dr. Berger, who has fixed the heights of 89 of these hills, considers them to compose three chains, separated from each other by high table-lands, and crossed by three very narrow openings. Snafield, the highest point of them all, is 2004 feet above the level of the sea, and North Barrule rises to 1804 feet. The mountains, commons, and waste lands are supposed to cover 50,000 acres, leaving above 90,000 acres for cultivation. England, Scotland, Ireland, and Wales are visible from the summits of the mountains on a clear day. The Neb, Sulby, and other streams which flow from the mountains enter the sea at Peel, Laxey, Douglas, and Ramsey. The coast is in many places very precipitous.

Rocks of mica-slate and clay slate compose all the mountains. These slates form also the coast at Spanish Head, where some precipices exceed 300 feet in height. The summit of one of the cliffs contains a druidical monument. Mica-slate is found at Snafield, the rounded summit of which is covered with grass. The base of this mountain is rich in metals. The galena which is found here contains from 90 to 130 ounces of silver per ton. Copper pyrites has 5 ounces of silver per ton, and black-jack sells for 5*l.* per ton. Clay-slate forms the largest portion of the island and nearly all the Calf. In one of the varieties of this slate, found towards its junction with the grauwacke rocks, the surfaces of the seams shine with metallic lustre. A stratified grey stone, which is used in building, is the second variety of clay-slate. The third variety, at Spanish Head, is used for lintels, &c. The roofing-slate, drawing-slate, and one of a vermillion colour near Braddah, make up the other varieties of clay-slate found in the island. The secondary slate formation, resting on the primary, consists of grauwacke, grauwacke slate, and old red-sandstone, and forms the greater part of the rocky sea-coast of the island, but does not extend much inland. The cliffs of this formation on the coast at Spanish Head seldom exceed 200 feet, and present a bold and picturesque appearance. There is a belt along the west coast, about two miles in width, consisting of old red-sandstone, of which Peel Castle is built. Limestone extends several miles on each side of Castletown. The steps at the main entrance of St. Paul's, London, presented to the dean and chapter by Bishop Wilson, consist of the first variety of this rock. Castle Rushen was built of the second variety, which is of a bluish-grey colour. The third variety, of a light grey colour, consists chiefly of shells. The fourth variety is magnesian, rarely contains organic remains, and its colour is yellow or white grey. Near Poolvash veins of trap, from two to six feet broad, break through the dark grey limestone. Boulders occur, of which the most numerous are granite, which differs from that of the island. Boulders of sienite, porphyry, and quartz are scattered from north to south, and the blocks of clay-slate and mica-slate mixed with the quartz prove it to belong to the island. The other boulders not formed of quartz appear to have come from the north and north-west, and enormous masses of them are found high up on the sides of one of the most elevated mountains. Boulders of sienite form a druidical circle near Bishop's Court. Granite in situ, containing mica, felspar, and quartz, is found in blocks on the north side of South Barrule. The decomposition of the felspar forms a fine powder, which is sold for polishing iron.

The soil in the south part of the island is a light clay formed by the decomposition of the clay-slate. The mountainous district is adapted only for pasture, and judicious culture alone can render the hilly parts productive. The soil however in the level country, extending from Kirkmichael to the north-eastern extremity of the island, consists of sand, clay, and peat, and contains excellent marl. The soil in the neighbourhood of Castletown is well adapted for wheat, and the abundance of lime supplies the farmer with a cheap manure. The climate, although variable, damp, and windy, is temperate. The highest and lowest temperatures observed are about 77° and 26° Fahr. respectively: the mean annual temperature is about 49°. The annual fall of rain is about 37 inches.

The harvests are frequently late, owing to the climate. The agriculture of the country, in consequence of the attention paid to the herring-fishery, was left very much to the women, who were accustomed to perform all the hard work of a farm, and frequently without their aid; the corn itself would have been unthrashed. The smallness of the farms, and the nature of the leases, were much impeded improvement. The breeds of cattle, although Bishop Wilson was not inattentive to their improvement, long continued very indifferent. When however Mr. Curwen formed an Agricultural Society at Workington, he did not neglect the interests of the island, but both by precept and example did everything in his power to improve its husbandry. Some excellent farmers from England and Scotland, who settled on the island, set the example of good farming. The annual value of the land among the hills varies from 5*s.* to 10*s.* per acre, and in some of the best cultivated districts amounts to 40*s.*, and near the towns is still higher. Many of the hedges present a very unsightly appearance, though more attention is paid to them than formerly. Wheat, and in some years potatoes, have been exported in very considerable quantities. The turnip husbandry has been much improved lately, and is steadily advancing. The largest part of the island is in the hands of yeomen, who farm their own estates, which are from 10 to 200 acres. Few properties are worth more than 1500*l.* a-year. There are about 8000 acres in wheat, which, at 2½ quarters per acre, produce 20,000 quarters; of barley 5000 acres, which, at 4 quarters per acre, produce 20,000 quarters; and 13,000 acres of oats, which at 3 quarters, produce 39,000 quarters. The Houghton sheep, peculiar to the island, are slow feeders and long in coming to maturity; their wool is much used for making stockings. A judicious system of turnip culture has recently been introduced into the Calf of Man, which will soon make this desolate spot productive. The best means for effecting durable improvements in the agriculture of the island are a judicious adaptation of stocks to the different soils. Thus the kyloes and galloways will suit inferior and mountain soils, while the short-horned may be introduced upon rich pastures. A judicious selection of such varieties of grain also as suit the soils and the climate would greatly increase the productiveness of the island.

The early history of the Isle of Man is obscure. It was governed by a succession of Norwegian kings, until Magnus, finding himself unable to preserve the Western Isles, sold them to Alexander III., king of Scotland, A.D. 1266. Soon after this Alexander reduced the Isle of Man, and appointed Regulus king, with whom he entered into a treaty, stipulating that the king of Man should furnish ten ships for Scotland, on condition that Alexander defended the isle from all foreign enemies. William de Montacute, with an English force, afterwards drove out the Scots, but his poverty prevented him from keeping it, and it thus became the property of the kings of England. In 1307 Edward II bestowed this island first upon the earl of Cornwall, and then on Henry Beaumont. The Scots, under Robert Bruce, recovered and possessed it until 1340, when the earl of Shaftesbury wrested it from Scotland in the reign of Edward III., and sold it to the earl of Wiltshire, who was afterwards executed for high treason, and his estates confiscated. Henry IV. granted it to Henry Percy, earl of Northumberland, and in 1403, in consequence of Henry Percy being attainted of high treason, and the Isle of Man forfeited, the king of England gave it, with the patronage of the bishopric and of other ecclesiastical benefices, to William Stanley and his heirs, afterwards the earls of Derby, for his aid in putting down the rebellion of Henry Percy, on condition that he should give the kings of England two falcons on their coronation. Thomas earl of Derby relinquished the title of king of Man, and took that of lord. James I. made a new grant of the island to William, sixth earl of Derby, which the parliament confirmed. James earl of Derby, in consequence of his adherence to Charles I., was taken prisoner and executed at Bolton, in 1651. His wife defended Castle Rushen, to which she retired, until Christian, on whom she relied, and who had the command of the forces, capitulated to Birch and Duckenfield, who had invaded the island with ten vessels. The parliament granted the island to Lord Fairfax. King Charles II., on his accession to the throne, gave it to the earl of Derby, the son of the earl who had been beheaded. James earl of Derby dying without issue, the inheritance devolved upon James, second duke of Athol, who was descended from the youngest daughter of the seventh earl of Derby. As both public justice and the revenue of the kingdom were injured by the island affording undue protection to debtors, outlaws, and smugglers, the British government passed an act in 1726, empowering the earl of Derby to sell his royalty and revenues. Various causes however prevented the sale being completed until 1765, when the duke of Athol sold his sovereign rights for 70,000l., with a civil patronage, and the [illegible] of Peel and Rushen. The duke however still retained the title of lord of Man, enjoyed all its ecclesiastical patronage, with [illegible], [illegible], [illegible], and other privileges. The duke, after repeated applications to government, obtained a perpetual grant of a fourth of the net customs revenue of the island, and enjoyed the honour of governor-general. By a subsequent arrangement with the duke on the part of the English government (George IV., c. 34) Great Britain now enjoys all the sovereign rights and privileges of the island. The customs of the ports are also vested in the crown, and a new rule of revenue laws was likewise introduced that year (Geo. [illegible]), which established the privilege of licensing such a stipulated quantity of certain goods charged with specified duties as will serve for the consumption of the inhabitants of the island.

No part of the kingdom abounds so much in Danish remains. The various tumuli, barrows, weapons, coins, and Runic characters afford clear evidence of the connection which the Northmen had with this island. Some Druidical temples have been discovered. The venerable remains of Rushen Abbey, which belonged to the Cistercian order, and of another near Douglas, for female recluses, supposed to have been founded by St. Bridget, show the influence of the church during the middle ages. The tumulus of Tynwald, which is approached by [illegible] steps on the east, presents the appearance of a truncated cone divided into three stages, which are raised about three feet above each other, and proportionally diminished both in circuit and width until they approach the summit, where the king of Man formerly sat on solemn occasions. The local laws of the island still continue to be read and promulgated here annually before the governor, two deemsters, keys, council, and various officers of state, and divine service concludes the solemnities of the day. The Tynwald Mount (which means either 'a fence for an assembly,' or 'a juridical hill') is situated near the intersection of the high road from Castletown to Ramsey with that from Douglas to Peel.

The whole island was formerly divided into 600 portions, called quarter-lands; but this number was increased, according to the authority of Feltham, in 1798, to 750. Possession for twenty-one years gives a good title to property. The right of pasturage for a certain number of cattle on the commons, and of quarrying stones and digging peat, belong to proprietors.

The principal towns in the island are Castletown, Douglas, Peel, and Ramsey. Castletown, situated in the south-west of the island, is a neat town, with spacious and regular streets. There is an open well-built square. The houses are situated on the opposite sides of a small creek, opening into a bay in the shape of a crescent, the extremities of which project into the sea. Castle Rushen, in Castletown, was built, according to tradition, in the year 960, by Guttred, a Danish prince, who is said to have been buried here. The stone glacis by which it is surrounded is supposed to have been built by Cardinal Wolsey. The stonework of the keep and several interior portions of the buildings are nearly entire; but, in consequence of the damages done by repeated sieges, the other parts have been repaired. The prisoners must have been lowered into the keep by ropes, as there are no steps for descending. The first stone of a neat and beautiful chapel in this town was laid by Bishop Wilson in 1698. The college, which has 100 pupils, and is conducted with great ability and success by two masters, was built by the exertions of the late Bishop Ward, aided by funds left by Bishop Barrow. There is also a neat chapel adjoining the college. The courts of chancery and common law are held in Castletown, and it is the residence of the governor. The House of Keys meet here. The number of houses in Castletown is calculated at 500, and the population in 1831 was 2077. When the last census was taken the number of prisoners in the gaol of Castle Rushen was 12 males and 3 females.

Douglas, in the parish of Kirkbraddan, formerly written Dufglass, and supposed by some to derive its name from the two rivers Dhu and Glass, is situated on the south-east coast of the island. The bay extends three miles, from Clayhead to Douglas Promontory, in the form of a crescent, and is sheltered from all winds except the south-east. The beauty of the scenery, the magnificent appearance of Castle Mona, built by the duke of Athol, and the numerous gentlemen's seats and neat cottages which surround the town, give the place a very agreeable appearance. The pier, which is 520 feet long and 40 or 50 broad, was built by the government at the cost of 23,000l.

The old streets are generally very irregular, but some which have been lately finished or are now in progress, are regularly built. The street which forms the river-front forms a striking contrast with the older part of the town. St. George's Chapel is pleasantly situated on an eminence at the west end of the town. There is a Lancasterian school capable of containing 750 scholars, which is well attended. The population of Douglas was 6788 in 1831; according to a more recent census it contains 800 houses, occupied by 1500 families, and a population of 7000. This town, which a century ago consisted of little more than clay-built huts, has now the chief trade of the island. There is a linen manufactory and a paper and woollen manufactory at Douglas.

Peel, formerly called Holm Peel, is on the west coast of the island. The castle, which is built on a small rocky island, encloses an irregular space of more than two acres, and is separated from the town by a narrow channel, scarcely a foot deep at low water. A strong wall, built as a security for the harbour, connects the island and castle with the mainland. There is a pyramidal mound of earth in the centre of the castle, surrounded by a ditch five feet and a half broad. The churches of St. Patrick and St. Germain are situated near this mound. The former was probably built before the Norman conquest; the latter, which was erected about 1245, is the cathedral church of the island, but is now only used for a burying-place. Peel has only one church. The Methodists are almost the only dissenters. There is an endowed school for grammar and mathematics. No attention is now paid to the harbour, and the pier is altogether destroyed. This town, which flourished through smuggling, is now, since it has ceased, in a very decayed condition. The population in 1831 was only 1722.

Ramsey is situated on a spacious bay, where there is safe anchorage, on the north-eastern coast of the island. It is built in a straggling and irregular manner. In this town the courts of law for the north part of the island are held. The Methodists are the most numerous dissenters. Its population in 1831 was 1754.

The herring-fishery employs about 250 boats, of from 15 to 30 tons burthen, and from 2000 to 3000 fishermen. The value of one of the boats, nets, &c., is above 100l. Successful years at present yield 40,000 or 50,000 barrels of herrings, of which one-third are used on the island. The deep fishing, if properly followed out, would add very much to the wealth of the island, and would form an active body of permanent fishermen.

Duties levied on imported goods, charges on vessels and boats trading to the island, the harbour dues, taxes on dogs, carriages, and public-houses, are the taxes of the island. The two last are expended in repairing harbours, roads, and bridges. The customs average from 20,000l. to 24,000l. After paying salaries to the officers employed by government, a surplus is annually remitted to England of from 12,000l. to 15,000l.

Two steam-vessels ply between Liverpool and the island; there is one from Dublin to Whitehaven which calls at Douglas, and there is constant communication between Scotland and the island.

The established religion is that of the Church of England, but all denominations of Christians have the free exercise of their religion. The Methodists are supposed to be nearly one-tenth of the population. The value of theteen out of seventeen livings in the diocese is 90*l.* per annum each. The episcopal see is supposed to have been fixed at Sodor in the ninth century, but the site of this place is not now known. The bishop of Sodor and Man, whose authority is wholly confined to this island, is a suffragan of the archbishop of York. He has no seat in the House of Lords. Several distinguished men have filled the see of Sodor and Man. Barrow, Wilson, and Hildesley have been rarely surpassed by any bishops of the Christian church. Barrow endowed schools, and formed a system of parochial instruction. Bishop Wilson, who filled the see for fifty-six years, secured the people of this island, by the Act of Settlement, a deliverance from their vassalage to the lord of the island, and manfully and successfully defended the interests of his clergy against the same noble family. He translated various works into Manks, and commenced the translation of the Scripture into that tongue, which was completed under Hildesley. The whole island felt for him the affection of a father, and the greatest pleasure of the people was to receive his benediction. Although offered a bishopric in England, he preferred his own little island and narrow income to rich preferment in his native country. His code for conducting the affairs of his diocese was so perfect, that it has been observed of it, that should all others perish, it would fully supply their loss. Many men have been distinguished by greater originality and vigour of mind, but few have equalled him in Christian charity and benevolence.

The bishop of Sodor and Man has an archdeacon and his assistant, two vicars-general, and an episcopal registrar, to assist him in managing the affairs of his diocese. Ecclesiastical courts for the proving of wills, granting administration, and carrying on suits against executors and administrators, are held by the bishop or his vicars-general for one half of the year, and by the archdeacon or his official for the other. There is an appeal from these courts in all spiritual affairs to the archbishop of York. The vicars-general hold a court every Friday. The clergy are assembled every year in convocation at the bishop's court, and a consistorial court is convened on the last Thursday of every month.

All the laws of the island are contained in one small volume. There are no barristers, and the services of the attorneys, who act both as attorneys and barristers, are in many cases rendered unnecessary by the clients pleading their own causes. Law is cheap, and litigation is common. The Manx agricultural population, who are generally yeomen, are frank, open, and kind; and most of them have all the necessaries, and some of them the comforts of life.

The House of Keys, which has both a legislative and judicial character, consists of 24 of the principal commoners of the island. They must have landed property, and have attained the age of twenty-one. They are now a self-elected body, but were formerly chosen by the people, and were the organ by which they acted. The two deemsters have equal jurisdiction, and are judges in civil and criminal cases. The Court of Chancery is held eight times in the year, where the governor acts as chancellor, with the assistance of the deemsters and other chief officers. The Court of Exchequer is generally held immediately after the former, and the governor, assisted by the deemster, is sole judge. This court takes cognizance of all matters connected with the revenues. The common-law courts are held at different places for the different sheadings into which the island is divided, called Glenfaba, Michael, Ayre, Garff, Middle, and Rushen. The courts at Peel are for the sheadings of Glenfaba, Michael, and Ayre; at Douglas, for Garff sheading; at Castletown for the sheadings of Middle and Rushen. All disputes about land and all personal actions for the recovery of damages are tried in this court before a jury. The deemsters administer the oath in the Manx language, deliver the charge, and receive the verdict. There is an appeal from the judgment of a court of common-law, first to the House of Keys, afterwards to the governor, and finally to the privy-council. There is a general gaol delivery twice in the year. The high bailiffs, who act as magistrates in the five towns of the island, were established in 1777, and can hear and determine all causes under forty shillings; they also maintain the peace and apprehend offenders.

Bishop Barrow formed a school, in 1666, in every parish in the island, and Bishop Wilson says, in 1747, 'We have petty schools, which are the foundation of catechising in every parish, and, though meanly endowed, may by care become special means of improvement.' The teaching of the Manx language, which is a dialect of the Erse or Celtic, has contributed to the general improvement of the natives, all of whom will probably in a short time be able to speak and read English. The present Archdeacon Philpots has taken much pains to promote the religious knowledge and intellectual improvement of the inhabitants.

Population.—Bede states that the island contained only 300 families, or about 1600 persons, in the eighth century. Holinshed, in 1584, says, 'There were formerly 1300 families in this island, but now scarcely half that number.' In 1667 it contained 2531 men between the ages of 16 and 60. In 1726 the population was 14,027; in 1757 it amounted to 19,144; in 1784, to 24,924; and in 1791, to 27,913. According to the census of 1831, the whole number in the island was 41,000. The increase during the ten years preceding 1831 amounted only to 919 persons; and the chief places where this took place were Douglas, Kirkpatrick, and Ramsey. The manufacturers in the Isle of Man are generally weavers and a few spinners.

MANAAR, Island. [CEYLON.]

MANAKINS, the name of a group of small birds remarkable for the rich tints of their plumage (*Pipra* of authors). Mr. Swainson makes them a subfamily of the *Ampelidæ*, under the name of *Piprinæ*. [PIPRA.]

MANATEE. [WHALES.]

MANCHA, LA, a province of Spain, bounded on the north by Toledo in New Castile, on the south by Andalucia, on the east by Cuenca and Murcia, and on the west by Extremadura. Its greatest length is 160 miles, and its greatest breadth 100. It contains about 7500 square miles. Its population, according to the census of 1788, amounted to 206,160 souls, of whom 749 were priests, 729 monks, and 610 nuns: within the last fifty years however it has somewhat increased, and may at present be estimated at more than 250,000.

The country for the most part consists of immense plains, elevated 2000 feet or more above the level of the sea, barren, sunburnt, and dusty, with scarcely a tree or house to relieve their dreary monotony, and affording only a scanty pasturage to vast numbers of mules and sheep. The towns and villages are mean and ruinous, indicative of the decay of the province. Cultivation is almost confined to corn, vines, and olives. In its great deficiency in natural beauty La Mancha bears a striking contrast to the fertile and picturesque regions to the south and east. Such is the centre of the province. Its frontiers are mountainous. On the south, forming the boundary between La Mancha and Andalucia, rises the lofty chain of the Sierra Morena; on the north are the mountains of Toledo, almost wholly in the province of that name; and on the south east of La Mancha, but within its boundaries, is the Sierra de Alcaraz.

The province is divided into Upper and Lower La Mancha. The capital is Ciudad Real, situated in a fertile plain, and formerly a flourishing city; but its trade and manufactures of wool and leather are now almost extinct, and its population has dwindled down to 8000 or 9000. Its streets are straight and regular, and it contains a spacious square, in which bull-fights are occasionally held. The other towns of importance are Almagro, Manzanares, Val de Peñas, Almaden, Quintanar de la Orden, and Toboso—immortalised by Cervantes.

The climate of La Mancha is intensely hot in summer, and rendered severely cold in winter by keen winds, though snow and ice are rare, except on the mountains. The soil is poor; it is parched by a burning sun, and scarcely refreshed by rivers; for the Giguela, Zancara, Mundo, Guadarmena, Azuer, Jabalon, Las Fresnedas, and Guadalen, are mere rivulets. The Guadiana alone, which rises in the Sierra de Alcaraz, and intersects the greater part of the province, is of considerable volume. About four leagues from its source it loses itself in a marsh, and after running under ground for five leagues, re appears at the small lakes called 'the Eyes of the Guadiana.' This remarkable phenomenon has given rise to the saying that there is in Spain a bridge five leagues in length. The population of La Mancha is principally agricultural. Wages for field labour are three reals, or sevenpence-farthing sterling per diem. The productions are corn, especially esparto—which grow in the neighbourhood of Ciudad Real, Manzanares, and Valdepeñas—and wines, which are excellent, and so cheap that a gallon costs no more than fourpence sterling. The wine of Val de Peñas is the most esteemed: it is a red wine, light and rosy, but, unless drunk in the province, is much injured in flavour by the skins in which it is customary to transport wines in Spain. Its price on the spot is about 2l. 10s. per pipe. La Mancha also produces some saffron and honey, but scarcely any fruit. The mules of La Mancha are famed for their great size; mules and asses are used for all the purposes of husbandry, as there are no horned cattle in this province. Beef is consequently not to be obtained, but mutton costs only about 2½d. and bread 1½d. per lb.

La Mancha is rich in mineral productions. There is a mine of silver, at present abandoned, together with several of antimony, near Almodóvar del Campo; and a mine of mercury, belonging to the crown, and very productive, at Almaden. [ALMADEN.] Ochre, rock-crystal, bole, calamine, and cinnabar are also found in La Mancha. There are likewise several springs of mineral waters, both hot and cold.

La Mancha formerly possessed some considerable manufactures, which have greatly decayed; but the spinning of wool still gives employment to several thousands of the population. Flannels, blond lace, leather gloves, hard soap, and gunpowder are also manufactured, but all on a small scale, and for the consumption of the province. Commerce is at a still lower ebb; and were it not for the productions of the soil with which La Mancha supplies the other provinces, it would be utterly dead. In exchange for these, La Mancha receives articles of luxury, and even many of the necessaries of life, especially in the way of clothing.

The Manchegos are grave, solemn, and punctilious, but courteous, generous, and good-humoured. The lower orders are hardy, industrious, frugal, and little addicted to pleasure. Everything indeed in La Mancha partakes of the melancholy character of the scenery; and were it not for the charm with which Cervantes has invested the province, and the similarity of manners and customs existing at the present day to those depicted in his immortal work, La Mancha would be to the traveller the most dreary and uninteresting part of Spain.

(Laborde's *Itinéraire Descriptif de l'Espagne*; Townsend's *Journey through Spain*; Inglis's *Spain in 1830*; Cruz, *Viage de España*.)

MANCHE, a department of France, deriving its name from La Manche (the Sleeve), or English Channel, on the coast of which it lies. It is bounded on the west, north, and north-east by the Channel; on the east by the department of Calvados; on the south-east by that of Orne; and on the south by those of Mayenne and Ille et Vilaine. Its form is irregular, but approximates to that of a rectangle, having its greatest length from north by west to south by east, from Cape de la Hogue to the neighbourhood of St. James, 82 miles; and its greatest breadth from Pontorson through Mortain to the border of the department of Orne, 29 miles. Its area is estimated at 2295 square miles, which is rather under the average area of the French departments, and about equal to the conjoint areas of the English counties of Kent and Surrey. The population of the department in 1831 was 591,284; in 1836 it was 594,382, showing an increase of only 3098, little more than a half per cent. in five years, and giving 259 inhabitants to a square mile. In amount and density of population the department exceeds the average of the French departments in the proportion of five to three; but is much exceeded by the English counties with which we have compared it. The chief town is St. Lô on the river Vire, in 49° 7′ N. lat. and 1° 6′ W. long., 152 miles from Paris in a direct line west by north, or 171 miles by the road through Mantes, Evreux, Caen, and Bayeux.

The coast-line forms two sides (the north and the west) of the rectangle to which the form of the department approximates, and part of the third side (the eastern): the northern part of the department is a peninsula, formerly known as the district of Le Cotentin, or Coutances, from the town of Coutances. The coast-line forms on the south-west and west side of the department the bay of St. Michael, which is occupied by sands, intersected by the channels of the rivers that empty themselves into the bay. From this bay the coast runs in a tolerably regular line north by west to the village of Carteret, receiving the Sienne, the Ay, and some other small streams. From the village and small sandy haven of Carteret the coast runs north to the rocky headlands of Cape Flamanville and the Nez (Nose or Ness) of Jobourg, between which is the small bay (Anse) of Vauville. Near the Nez de Jobourg is Cape la Hogue, the north-western point of the rectangle. Opposite to the western coast are the little island of Chausey with its granite quarries, and the Channel Islands, which belong to England; Jersey is opposite the mouth of the Ay, and Aurigny or Alderney, the nearest to the French coast, is opposite Cape la Hogue, from which it is separated by the Raz de Blanchard, or, as the English term it, the Race of Alderney. The northern coast from Cape la Hogue to Pointe Barfleur, the north-eastern point of the rectangle, forms a shallow bay, at the bottom of which are the roadstead and town of Cherbourg. The roadstead is defended by a digue, or *breakwater*, having a small island at each end; that at the east end is called *Pelée*. Near Cherbourg the coast is high and steep. From Pointe Barfleur the coast runs southward in an irregular line to the estuary of the Douve and the Vire, which is full of shoals. This eastern coast is skirted above high-water mark by a marshy flat a mile and a half broad in some places, along the immediate margin of the sea by sandy downs, and below high-water-mark by broad sands and rocks; it has opposite to it the small island of St. Marcouf.

The department has not any mountains, but a range of hills, some of them of considerable height, branching from the Armorican chain, extends through it from south to north. The principal streams flow from these heights eastward or westward into the sea, owing to the proximity of which all the watercourses are short.

The primitive rocks compose the greater part of the department, but a part of the western coast and of the country about Valognes, Carentan, and St. Lô is occupied by later formations. Between Carentan and Valognes the elevated land behind the low marshes that skirt the shore is composed of blue lias, which extends to a considerable distance inland. This lias closely resembles, in its fossil remains, that of the south of England; the white and blue strata are commonly much intermixed. The new red sandstone is abundant between Carentan and St. Lô; it is chiefly composed of red marl and red sandstone mixed with the usual blue and white strata; between Carentan and Isigny it is yellowish mixed with red and grey, and is tolerably compact. Red marl and red sandstone belonging to this formation are found near Valognes and along the coast intermingled with gravel beds composed of the rocks of this formation, intermixed with quartz rock, on which in several places the new red sandstone is found to rest. This quartz rock has in some parts been denuded; it is found between Valognes and Cherbourg alternating with argillaceous slate. Argillaceous slate and grauwacke occupy the west of the department about St. Lô. Granite, resembling that of Dartmoor, is found at St. Vaast near Pointe Barfleur.

A bed of limestone, probably belonging to the supracretaceous rocks, is quarried between Carentan and Valognes; and another limestone of uncertain date is found in the immediate vicinity of the latter place. (*Geol. Transact.*, 2nd series, vol. i.)

The mineral treasures of the department are not great. There is one iron-work, having one furnace for making pig-iron, and one forge for wrought-iron. No coal is procured, but granite, slates, and stones for millstones and whetstones are quarried; kaolin and potters' earth are procured; and there are some mineral springs, and in the marshes considerable saltworks.

The largest river is the Vire, which rises in the department of Orne, and enters this department on the east side near Tessy, from whence it flows northward, just within and in one part on the boundary of the department, past St. Lô into the English Channel. The whole length of the Vire is about 50 miles, for about eight of which it is navigable. The Douve rises near the west coast of the peninsula of Cotentin, across which it flows in a winding channel to the eastward, until it falls into the same inlet or estuary as the Vire. Its whole length is about 34 miles, for above half of which it is navigable. The Merderet and the Sève, small feeders of the Douve, about 12 miles long, are navigable, the first for about four miles, the second for about three;

and the Taute, another small feeder of the same river, 20 or 22 miles long, is navigable for about 14 or 15 miles. The Sinope and the Saire run into the sea on the east coast; the Divette, at Cherbourg on the north coast, and the Ay on the west coast: these are all small. The Sienne rises in the department of Calvados and flows north-west across the department into the sea; its length is about 38 or 40 miles, of which only five are navigable. Its principal feeder is the Soulle, which flows by Coutances; the Airon and the Venne are smaller. In the south of the department are the Celune, or Selune (34 miles long, with five miles of navigation), which rises in the south-eastern side of the department, and flows across it into the sea opposite Mont St. Michel, receiving in its course the Deron, the Brevon, and the Oir; the Sée (28 to 30 miles long), which falls into the sea near the Celune; and the Couesnon [ILLE ET VILAINE], of which only a small portion, including a navigation of five miles, belongs to the department.

The Terette and the Madelaine, two streams to which the government returns assign a navigation of four and five miles respectively, are not marked, at least under those names, in Brué's map. The total amount of inland navigation is about 75 miles.

The number of Routes Royales, or government roads, is eight, of departmental roads 23: together 31. The aggregate length of the government roads was (1st Jan., 1837) 227 miles, of which 213 miles were in repair, 11 miles out of repair, and three miles unfinished. The aggregate length of the departmental roads was 360 miles, of which 201 were in repair and 159 out of repair. The principal road is that from Paris to Cherbourg, which enters the department on the east at the village of Anville on the Vire, between Isigny (Calvados) and Carentan, and runs through Carentan, Sainte-Mère-Eglise, and Valognes. The road from Paris to St. Lô branches off from the foregoing at Bayeux (Calvados) and entering the department on the east, at St. Quentin on the Elle, a small feeder of the Vire, runs to St. Lô. The road from Paris to Avranches branches off from the Cherbourg road at Caen and runs through Villedieu. Roads run from St. Lô northward to Carentan; westward to Coutances, where it joins a road from Carentan to Granville; and southward to Villedieu, where it joins the road from Paris to Avranches. Roads run from Granville to Villedieu and to Avranches; and from Avranches to Pontorson on the Couesnon and so into Bretagne. A road from Caen (Calvados) to Rennes (Ille et Bretagne) crosses the south-eastern corner of the department through Mortain and St. Hilaire. The bye-roads and paths amount to nearly 14,000, with an aggregate length of nearly 10,000 miles.

The arable land of the department comprehends nearly two-thirds of the whole soil; the corn grown exceeds the consumption of the department and the average produce of the departments of France, especially in buckwheat and barley; more buckwheat is grown than of any other grain; the quantity of oats, rye, and maslin or mixed corn raised is small. Flax and hemp are raised in great quantity. Pulse is good; the fruit is of middling quality. The quantity of ground occupied for orchards is perhaps greater than in any other department; the apples are grown for making cider. The quantity of meadow-land is also very considerable, nearly one-sixth of the whole department; horses and horned cattle are very numerous, and the cattle are of one of the finest breeds in France. The proportion of cows is great, and a large quantity of butter is exported. The breed of sheep is not very good; it is considered that the long woolled Leicester breed might be introduced with great advantage. The rearing of swine, poultry, and bees is in some parts an object of great attention. There are no vineyards and but little woodland; the forest trees are chiefly oak, beech, and birch.

The department is divided into six arrondissements, as follows:—

		Area in square miles.	Population in 1831.	Population in 1836.	Communes.
Saint Lô	E.	436	99,250	100,717	120
Coutances	W.	512	136,847	135,980	137
Valognes	N. and Central	401	95,660	95,950	118
Cherbourg	N.	233	75,488	76,673	73
Avranches	S.W.	379	110,468	110,821	124
Mortain	S.E.	337	73,571	74,241	73
		2,298	691,284	694,382	645

There are 49 cantons, or districts, each under the jurisdiction of a justice of the peace.

In the arrondissement of St. Lô are, St. Lo (pop. in 1 8154 town, 8421 whole commune; in 1836, 9065 commu [Lô, St.] and Tessy, on the Vire; Thorigny, or Tor (pop. 2121 town, 2184 whole commune), and Cericy, in country east of that river; Guilain, near the source of Venne; Canisy and Marigny, near St. Lô; and Carentan, the junction of the Taute and the Douve. Thorigny formerly a fortress, built during the occupation of Norm die by the English, on the site of which was erected a nificent mansion, of which only one wing remains. Car tan (pop. 2292 town, 2773 whole commune), situated marshy and unhealthy district, is surrounded by ruined and defended by a strong castle. Trade is carried on corn, cider, hemp, flax, honey, butter, fish, cattle, horses. There are some manufactures of lace and cott

In the arrondissement of Coutances are, Coutances in 1831, 8957; in 1836, 7663 for the commune) [TANCES] and Cerisy-la-Salle, on the Soulle; Hamb Hambye (pop. 3684), St. Denis, Gavray, and Cerences, or near the Sienne; Brehal, in the country south-west that river; Périers, near the Taute; Créance and L on or near the Ay, the mouth of which forms a small bour; La Haye-du-Puits, on the Houillabec, a small fe of the Douve; and Pretot, between La Haye-du-Puits Carentan. Cerisy-la-Salle has a manufactory of calico, near Créance and Lessay are considerable salterns. T sailors of Agou, a village of 1500 inhabitants, at the mo of the Sienne, which forms a small harbour, are engaged the Newfoundland cod-fishery.

In the arrondissement of Valognes are, Valognes (p 1831, 6338 town, 6940 whole commune; in 1836, 665 mune), Montebourg (pop. 2423 town, 2523 whole comm Sainte-Mère-Eglise, and Le Homme, on or near the M Bricquebec (pop. 4255), St. Sauveur, and Pont l'Abb or near the Douve; Barneville, on the haven of Car on the west coast; and Barfleur, Tatihou, Saint-V (pop. 3502), Quettehou, and La Hougue, on the eas coast. Valognes is pleasantly situated in a valley. It said to have owed its origin to the destruction by fire antient city close by, which Malte Brun and others, probably by the modern name of the commune in wh ruins stand (Allaume), suppose to have been the Alau the antients, but which M. D'Anville considers, and better reason, to have been Crociatonum, the chief t the Veneli, or Unelli. There was antiently a strong at Valognes, which was taken by Bertrand du Gue (A.D. 1364) from Charles le Mauvais, king of Navarre. T town was several times taken and retaken during the of the English in France, under Henry V. and VI. was again the object of contest in the civil wars of the teenth century, and in the troubles of the minority of L XIV. The inhabitants manufacture porcelain, felt, yarn, and lace; there are dye-houses and tan-yards; trade is carried on in linens, gloves, and paper. The m facture of woollen-cloth, once flourishing, has gone to There are a public library, a high-school, an agricu society, and a poor-house or hospital, by the inm which lace is made.

In the arrondissement of Cherbourg are, Cherbourg in 1831, 18,377 town, 18,443 whole commune; in 19,315 whole commune) [CHERBOURG], on the sea, at mouth of the Divette; Les Pieux, near the west coast St. Pierre-Eglise (pop. about 2300), near the north between Cherbourg and Pointe Barfleur. At Saint-P Eglise is a large linen manufactory, and at the villag Tour-la-Ville (pop. 3624) near Cherbourg are slate qua there were formerly extensive glass-works here. At St. V near St. Pierre-Eglise, cotton-yarn and calico are manu tured.

In the department of Avranches are, Avranches (1831, 7000 town, 7269 whole commune; in 1836, 769 mune) [AVRANCHES] and Brecey, on the Sée; Vill (pop. 3074 town, 3095 whole commune), on the Sienne; Lande, on the Airon; La Haye-Pesnel and Sartilly, in country north of the Sée; Granville (pop. 7350) [G VILLE], Genest, and Pontorson, on or near the west Ducey, on the Celune; and Saint-James (pop. 1790 t 3104 commune), on the Brevon. Villedieu owes its o to a grant of the territory in which it stands, made Henry I. of England, duke of Normandie, to the Hosp of Jerusalem. The village, which rose on the possession of of the Hospitallers, called Theopolis, or God's town (in French, Ville Dieu), grew to a town. It is a busy place; there are copper-foundries, brass and earthenware manufactories, and a hair-cloth manufactory. Leather and lace are made; the latter chiefly by women. Pontorson is on the Couesnon or Coesnon, near the border of the department. The inhabitants trade in linen and lace. The latter, which is of excellent quality, is made in the hospital or poor-house, and affords employment and subsistence to a considerable number of poor. Saint-James is built on a hill, surrounded by valleys which present very picturesque and varied scenery. It is of uncertain origin; but the extent of the circuit of the walls, and the number of subterraneous vaults which yet remain, show it to have been formerly a place of greater importance. It was repeatedly taken and retaken in the wars with the English. There are several manufactures, and at the nine yearly fairs considerable business is done in linens, woollen stuffs, and thread.

In the arrondissement of Mortain are, Mortain (pop. in 1831, 1922 town, 2511 whole commune; in 1836, 2521 commune) and Juvigny, between the Sée and the Célune; Barenton (pop. 3196), near the Célune; St. Hilaire-du-Harcouet (pop. 2064 town, 2749 whole commune), on the Deron; Le Teilleul, in the country south of the Célune; and St. Pois, in the country north of the Sée. Mortain is in one of the most hilly tracts in the department. The only manufacture is that of earthenware. At St. Hilaire-du-Harcouet there is a college or high-school.

The population, where not otherwise specified, is that of the commune, and from the census of 1831.

The manufactures of the department are woollen cloths, serges and other stuffs, linens, lace, cotton yarn and goods, haircloth, earthenware, glass, wax candles, ironmongers' and other hard wares, common cutlery, paper, leather, and soda from sea-weed. There are in the arrondissement of Valognes two establishments for the manufacture of sheet zinc, zinc pipes, zinc nails for sheathing ships, &c. There are several ship-building yards and salterns on the coast. The coast and Newfoundland fisheries are actively pursued, and much trade is carried on with the Anglo-Norman Isles, Guernsey and Jersey.

The department forms the diocese of Coutances, the bishop of which is a suffragan of the archbishop of Rouen. It is in the jurisdiction of the Cour Royale and the circuit of the Académie Universitaire of Caen; and in the fourteenth military division, the head-quarters of which are at Rouen. It sends eight members to the Chamber of Deputies.

In respect of education, this department is rather above the average of France. Of every hundred young men enrolled in the military census of 1828-29, forty-three could read and write, the average of France being thirty-nine. There are seven Colléges Communaux, or district high-schools, and two schools of navigation.

This department constituted in antient times the country of the two Celtic people, the Abrincatui and the Unelli or Venelli. Ingena, the capital of the former, from whom, in the fourth century, it took the name Abrincatui, is the modern Avranches; and Crociatonum, the chief town of the latter, was near the modern Valognes. Coriallum was probably at the little haven of Goury, near Cape la Hogue; and Alauna at Les Moutiers d'Alonne, near the haven of Carteret. Cosedia, which some have endeavoured to prove was the same as Constantia, the modern Coutances, was probably near the harbour of St. Germain. Fanum Martis was perhaps Mont Martin-sur-Mer, near the mouth of the Sienne; and Legedia was perhaps on the west coast, at the little haven of Lingreville, near Granville, which last place may be probably identified with the Roman Grannonum. Augustodurus, a Roman town mentioned in the Peutinger Table, was probably on the Vire, not far from Mont Martin-en-Graignes. The æstuary of the Douve and Vire is probably the Argenus of Ptolemy, if that geographer speaks of a *river*, not a town; and the Tetus of the same writer was probably either the Sée or the Célune.

In the middle ages the department constituted the districts of Cotentin and Avranchin. They were among the tracts ceded by Charles le Simple to the Northmen, and formed part of the duchy of Normandie. It was the part of Normandie which the English retained the longest.

MANCHESTER is situated in the hundred of Salford and the county of Lancaster, 168 miles N.W. by N. of London, direct distance, or 187 miles by the present mail-coach road. The parish, which comprises several townships, had in 1773 a population of 19,796, and in 1831, 270,963, of which there were in the township of Manchester 142,026. From 1801 to the last census, in 1831, the population had more than doubled itself; nor has the increase come to a stand. In Pigot's 'Manchester and Salford Directory,' for 1829, were given 34,900 names of resident householders; in that for 1839 above 44,000; in the former the number of streets was 2740; in the latter 3600. Under the Reform Act Manchester sends two members to parliament. In the first election (1832), contested by five candidates, there were given 9689 votes; in the election in 1835 four candidates received 9636 votes.

Under the Municipal Act the borough has a commission of the peace, is divided into fifteen wards, has a mayor (Thomas Potter, Esq., the first mayor), sixteen aldermen, and forty-eight councillors, whom the act empowers to hold a Court of Record for the trial of civil actions, provided the sum or damages sought to be recovered do not exceed twenty pounds. Under the same act the borough has also a commission of the peace and the right of holding quarter-sessions.

The town is not distinguished for architectural beauty; its chief streets are occupied with warehouses and shops, the more and the less opulent inhabitants residing, at a greater or less distance from the centre of the town, in dwellings separate from those in which they conduct their business, many of which are spacious and beautiful. There are however some objects of architectural interest in Manchester. Under the sanction of acts of parliament much has been done for the improvement of the town, both in convenience and appearance. Market-street, the chief mart for retail business, was not many years ago a mere lane: it is now a very handsome street. The improvement was completed in 1834, when the total outlay was 232,925*l.* The Manchester Improvement Committee have also judiciously applied the profits of the gas-works, which are in the hands of the Commissioners of Police, to the improvement of the township; 20,057*l.* were thus expended by them in the year 1835. Among the public buildings worthy of notice may be named the chaste portico of the Subscription Library, and the truly classic and handsome Royal Institution, both in Mosley-street, and the hall of the Museum in Peter-street. The Infirmary is a fine building, and has an advantage which is rare in Manchester, namely, that of being in a favourable situation. Several new churches have recently added to the appearance of the out-districts of the town, among which the churches at Pendleton and Hulme deserve special mention: but even these are inferior to the beautiful church in the pointed style now (1839) being erected by Mr. Atkinson, architect, near Smedley lane, Cheetham Hill.

Situation and Inland Communication.—Manchester stands on the south-east bank of the river Irwell, by which it has a communication with the Mersey, Liverpool, and the ocean. It is situated in a district which contains some of the best coal strata of England, a circumstance to which the place is in no small degree indebted for its prosperity. The weekly consumption of coal in the town and neighbourhood is estimated at 26,000 tons, the charge of which is for the factories about 8*s.* per ton, for private houses 12*s.* per ton. In 1836, 913,991 tons were brought into Manchester.

The climate of Manchester is not so genial as that of the more southern districts of the kingdom; but the unfavourable impression which prevails respecting it is much exaggerated. The following statements are made on the authority of Dr. Dalton (*Memoirs of the Manchester Philosophical Society*, second series, vol. iii., p. 483, et seq.). The mean height of the barometer at Manchester is 29·85. The mercury is higher in the summer months than in the winter. The general annual mean of temperature is nearly 49°. The mean annual fall of rain is 36·140 inches; while at Lancaster it is 39·714, at Dumfries 36·919, and at Kendal 53·944. The first six months of the year must be considered as *dry* months, and the last six months as wet months. April is the driest month in the year, and the sixth after, namely, October, is the wettest, or that in which the most rain falls, in a long continued series of years, in the immediate neighbourhood of Manchester.

Manchester has the credit of having given an impulse to our means of internal communication, and has reaped an ample reward. The achievements of Brindley were prompted by the desire which the duke of Bridgewater had of sending his coal from Worsley to Manchester at a small expense. [BRINDLEY.]

Manchester now possesses the means of water-communication with almost every part of the country. In the railroad enterprise Manchester has held a prominent station. It furnished its full share of the capital employed in the formation of the Manchester and Liverpool railway, the act for which was obtained in May, 1826; the road was completed by Midsummer, 1830, and formally opened on the 15th of September of the same year, in the presence of half a million of people assembled along the line. By the Report of the directors, dated January, 1839, declaring a dividend of 5*l.* per cent. for the half-year previous, it appears that the receipts within that period were as follows:—Coaching department, 79,277*l.*; merchandise, 54,215*l.*; coal, 3201*l.*: total, 136,693*l.* The expenses were 80,978*l.*, leaving a balance for distribution among the proprietors of 55,714*l.* The amount of expenditure in construction of the way and works is stated at the enormous sum of 1,376,073*l.* for a length of road only thirty miles. The Manchester and Bolton railroad was formally opened on the 26th of May, 1838. Its length is ten miles, and its cost 650,000*l.* A continuation of the line to Preston and Lancaster is in progress. A dividend of 1*l.* 10*s.* per share was declared on the 9th of January, 1839. The Grand Junction railway connects Manchester with Birmingham and London: there are 10,918 shares in this railway, and the outlay was 1,512,150*l.*; it was opened in September, 1837, and has paid on the first year 10*l.* per share, on the last six months 12*l.* The North Union connects Manchester with Wigan and Preston. There are also in course of formation lines to Leeds, direct to Birmingham, to Sheffield, &c.

History.—Manchester, as its name shows (Man, castra), was a Roman station, the Mancunium of the Antonine Itinerary. Aldport, the original of Manchester, is supposed by the learned Whitaker to have taken its rise in the reign of Titus, and during the continuance of the Romans in this island it was indebted to them for many of the germs of civilization, and especially for an improvement in the woollen manufacture, a branch of trade which is said to have been introduced from Gaul before their invasion. Of the roads which were planned by Agricola, Manchester had four; two running from east to west, and two from north to south: inferior stations, at places now known by the names of Singleton Brook, Prestwich, and Broughton, were connected with the Manchester camp. Under the Saxons Manchester became the abode of a Thane, who from his baronial hall dispensed a certain sort of justice, and furthered the improvement of the place. At an early period it had two churches, one of which, St. Michael's, is mentioned in Domesday Book. In 870 the Danes got possession of Manchester. After the Norman conquest William gave the place to William of Poictou. The third baron of Manchester was concerned in wresting Magna Charta from King John. In the year 1301 Thomas de Grelley granted the 'Great Charter of Manchester.' In 1307 the baron of Manchester was summoned to parliament, and appears to have been a favourite with Edward I., who made him Knight of the Bath. From the Grelleys the barony descended to the family of De la Warre, and John, the first of the line, was called to parliament in the ninth year of Edward II. He and his successors distinguished themselves in the battle of Cressy, during the Wars of the Roses, and most of all at the period of the Reformation, the baron of Manchester being one of those who apprised the pope that his continued resistance to Henry's wishes in regard to the divorce would lead to the extinction of his supremacy in England. At length the manorial rights vested in the family of 'Mossley of the Hough.'

The dissensions excited by the Reformation were strongly experienced in this town. Collyer, the warden of the collegiate church, refused to acknowledge the spiritual supremacy of Henry VIII., and many of the great families in the neighbourhood remained for a long time attached to the see of Rome. In the civil wars Manchester ranged itself on the side of the parliament (Puritanism having gained an ascendancy in it), and sustained a siege conducted by Lord Strange. On the cessation of the contest, Presbyterianism replaced Episcopacy; Heyrick, the warden of the collegiate church, being himself instrumental in bringing about the change. In 1646, when Lancashire was converted into an ecclesiastical province under the Presbyterian forms, Manchester, with some neighbouring places, was constituted the first classical division of the county. Under Cromwell the electors chose a representative in the person first of Mr. Charles Worsley, and then of Mr. R. Ratcliffe. The Act of Uniformity under Charles compelled about seventy ministers to quit their livings in Lancashire, and among others, the Rev. H. Newcombe, who became minister of what is now called Cross-street chapel, and may be considered the father of non-conformity in a town which has from the first been distinguished as possessing 'a greater dissenting population than most others in the kingdom.' A strong Jacobinical feeling soon grew up, and the Rebellion of 1745 had many friends and supporters in Manchester, even among the leading inhabitants and the clergy of the collegiate church. Prince Charles himself was entertained in the town at the residence of Mr. Dickinson, in Market-street, a house subsequently known as an inn, under the title of the 'Palace,' and which has recently been pulled down to give place to warehouses. It was not till 1783 that the town had a nightly watch, nor did it possess a Police Act before 1791. The political strife which characterises the last half century, and by which great changes have been effected in the constitution of the country, displayed itself at a very early period in Manchester, and was supported and extended by means of 'Reform Clubs' and 'Church and King Clubs.' In 1791 a 'Constitutional Club' was formed. The threat of a French invasion excited indignation and much warlike display. Immediately after the peace in 1815, the desire for 'Reform' began to manifest itself in Manchester in a very decided manner. By the Reform Act Manchester obtained, in common with many other towns in the kingdom, the elective franchise.

Manufactures.—Cotton is the chief article employed in the manufactures of Manchester. Of late the spinning and weaving of silk have been introduced, and it has manufactures of woollen, small wares, hats, umbrellas, and of machinery, which last has risen to great importance and perfection.

The commercial spirit dates back to a very early period. It is enough however to mention, that in the time of Henry VIII. and Edward VI. the town was distinguished for its manufactures. The more rapid expansion of trade began in the seventeenth century, and one who is known as a benefactor to the town, Humphrey Chetham, was among its most eminent tradesmen. The enormities of the duke of Alva in the Netherlands, and subsequently the revocation of the edict of Nantes, brought many enterprising and skilful foreigners into the district, and gave energy and effect to the native commercial impulse. At first the woollen was the only branch of trade, but since the middle of the last century the cotton business has nearly superseded the antient fabric. The natural advantages possessed by the town, together with the strength of character of the natives, was undoubtedly the original and the main cause of the growth of its trade and prosperity; but the series of brilliant inventions and discoveries applied, improved, or originated in the district of Manchester, which comprise the steam-engine, the spinning-jenny, the mule-jenny, the fly-frame, the tube-frame, the mule, &c., have proved most effective instruments in aiding the development. The early series of inventions which gave energy to the cotton manufacture were completed about 1780. Before their introduction—namely, until 1751—the importation of raw cotton into this country had gone on increasing slowly; the supply being in 1701, 1,985,868 lbs.; and in 1751, 2,976,610 lbs. But in 1780 it had increased to upwards of 6,700,000 lbs.; while in 1800 it reached 56,000,000 lbs. Equally striking is the official return of the export of cotton goods: in 1701 the value was 23,253*l.*; in 1800, 5,406,501*l.* Again, in 1838, the following, according to Burnd's 'Commercial Glance,' was the amount and value of manufactured cotton goods exported:—

	lbs.	£
In manufactured goods .	120,784,629	11,746,475
In yarn . . .	113,753,387	6,043,138
In thread . . .	2,361,984	177,224
	236,900,000	17,966,837

The value of the cotton trade to the country has been estimated at 34,000,000*l.* annually; the capital employed at 20,000,000*l.*; the amount of wages annually paid, 17,000,000*l.* and that 1,500,000 people depend on it for their subsistence. Till within the last year or two, the progress has been steady and rapid; it is not however easy to affirm that it will continue as satisfactory; at the moment we write

(March, 1839), numerous mills in Manchester and the neighbourhood have ceased working, in part or altogether.

The processes of throwing and weaving silk were extensively carried on at Macclesfield several years before they reached Manchester. The silk-mill of Mr. Vernon Royle, erected in 1819-20, was the first brought into operation in the latter town. Since then the trade has rapidly increased. In 1819 there were in it about a thousand weavers of mixed silk and cotton, and fifty of pure silk goods; in 1836 there were in the county (Manchester being the principal locality) twenty-two throwing-mills employing about four thousand persons. Printing is another branch of the silk business, chiefly, if not exclusively, carried on at Manchester. Dyeing of silk is also extensively pursued, and in fact the town is becoming the centre of transactions in the silk trade.

Property in Manchester has greatly increased in value, and the habits of the manufacturers have undergone an entire change. It is curious to contrast the picture which Aikin gives with what is now seen in the stupendous warehouses and the mansions and palaces which are found in Manchester and its vicinity. 'An eminent manufacturer in that age (1695) used to be in his warehouse before six in the morning, accompanied by his children and apprentices. At seven they all came to breakfast, which consisted of one large dish of water-pottage, made of oat-meal, water, and a little salt, boiled thick, and poured into a dish. At the side was a pan or basin of milk, and the master and apprentices, each with a wooden-spoon in his hand, without loss of time, dipped into the same dish and thence into the milk-pan, and as soon as it was finished they all returned to their work.' 'When the Manchester trade began to extend, the chapmen used to keep gangs of pack-horses and accompany them to the principal towns with goods in packs, which they opened and sold to shopkeepers, lodging what was unsold in small stores at the inns.' In 1816 the annual value of property in the township of Manchester was 405,986*l.*; in 1836 it had reached 475,088*l.* In the township of Ardwick property had in 1836 nearly doubled in the short space of 17 years: in that of Chorlton-on-Medlock, a town has within a few years been actually created through the erection of factories; in 1801 its population was 675, in 1831 20,569; in 1815 the annual value of property was 54,844*l.*, and in 1835, 117,669*l.* Nor need there be any surprise felt at this when it is known that mills of the first character require an outlay of from 50,000*l.* to 100,000*l.* In the reign of William and Mary the taxable property in Manchester was rated at 4375*l.*; in the year 1828 the amount of assessed taxes charged was 26,470*l.* The circulation of the branch bank of England in Manchester, which in 1828 was 259,000*l.*, had risen to 1,340,000*l.* in 1837, though in the interval several joint-stock banks had been established. In 1794 the poors'-rate at five shillings in the pound produced 9270*l.*, in 1834 it realised on a rate of half-a-crown 44,896*l.* In 1790 it was mentioned as an extraordinary fact that Manchester paid in postages 11,000*l.*, being a larger amount than any other provincial town; in 1838 this sum had risen to 62,232*l.* In the single article of bricks the town paid to the excise in 1835 no less a sum than 35,716*l.* The value of land has undergone a proportional increase, as may be judged of by the following sales made of land in the central parts of the town: in 1834, 71 square yards in King Street were bought for 354*l.*; 50 yards at the corner of Todd Street for 280*l.*; 230 yards in Smithy Door for 2990*l.*; even 9*l.*, 10*l.*, 12*l.*, and yet higher sums have been given per square yard for land in situations eligible for those immense receptacles of goods, the larger warehouses. Land at the upper end of Market Street and Mosley Street, which 50 years ago was sold for 4*d.* per square yard annual rent, has been sold for 20*s.* a yard annual rent.

As to the intellectual and moral condition of the working classes, there has doubtless been great exaggeration, but it is equally true that in that condition there is much to deplore. The prevalence of the factory system has broken up the old domestic manufacture and thereby destroyed old domestic habits; it has also called from every district of the kingdom, and especially from Ireland (there are at least 50,000 Irish in Manchester), masses of people heterogeneous in their character, yet all more or less ignorant and uncultivated, and not likely therefore to coalesce speedily into a compact form of civilised existence. Most of them have been much bettered in their circumstances without having found an equal increase of morally improving influences. Children by the amount of their wages have become independent of their parents; girls have been sent into the mill before they have learnt the rudiments of domestic duty, and mothers, whose presence in their own houses is indispensable, work for twelve hours in the day amid a mass of people, young and old, with whom they have little or no connection, and from whom in consequence they can scarcely derive any improvement. It must also be said that the atmosphere of the factory is unnatural and consequently unhealthy, while the degree of heat tends to the premature development of the passions, and, as the least baneful consequence, to early, improper, and improvident marriages. The charges against the factories, of being the scenes of violence and cruelty to children, of extortion against the men, as destructive alike of life and morality, may be considered as gross extravagances or little better than falsehoods; but it is not the less true that neither their moral nor their physical atmosphere is favourable to the well-being of the work-people; that, with some honourable exceptions, the masters are heedless of the comforts and improvement of those whom they employ, and think exclusively of the wealth they can extract from their establishments, and that thus there has arisen on the part of the workmen a feeling of jealousy, of dislike, of sullen discontent, which, added to other depraving influences, makes their moral tone hard, disposed to violence, and almost reckless, while their congregating together in masses gives them opportunities of communicating their feelings one to another and of concentrating their power. The system has not been sufficiently long in general operation to afford accurate means of judging of its effect on health and life; it has also been tried, in relation to these matters, under favourable circumstances, since there has been a continual influx of fresh population to the mills from rural districts or small towns, and therefore statistical tables cannot furnish any adequate means of forming an opinion; but in relation to children, the wonder is, that any one should have doubted of the injurious influence which it has upon their health and consequently on their character. As it is, the moral condition of the young, and of the homes whence they come, are in very many cases bad. When the mother is in the factory, the home must be in disorder. When parents subsist on the earnings of their children, as in many instances, the relations of domestic life are subverted; the weak labour, the strong are idle, idleness begets vice, vice is the parent of discontent, and this leads to the use of intoxicating drinks; the parent is moreover punished in the disobedience, if not insolence, which soon manifests itself on the part of the children, who are well aware how much the family depends on their earnings. Of 53,623 persons employed in mills, May, 1836, in the parish of Manchester, 35,289 were females; 37,930 were above the age of 18 years, and 16,969 were below the age of 18. The following table gives the average net weekly earnings of the different classes of operatives in the cotton factories of Manchester, Stockport, Dukinfield, Staley-bridge, Hyde, Tintwistle, Oldham, Bolton, &c., drawn from the Returns of 151 mills, employing 48,645 persons, in May, 1833:—

Denomination of process in which employed.	Class of Operatives.	Classification as respects age and sex.	Average weekly net earnings.
			s. d.
Cleaning and spreading cotton	. . . . .	Male and female adults, and some non-adults	5 9
Carding . . .	Carders or overlookers	Male adults	28 6
	Jack-frame tenters	Principally female adults .	8 6
	Bobbin-frame tenters	Do. do. .	7 2½
	Drawing tenters	Do. do. .	7 6½
Mule spinning .	Overlookers .	Male adults	29 2
	Spinners . .	Male and female adults, but principally the former	26 9
	Piecers . .	Male and female adults and non-adults, but principally the latter	5 4½
	Scavengers .	Male and female non-adults	3 10½
Throstle spinning	Overlookers .	Male adults	22 9¼
	Spinners . .	Female adults and non-adults	7 9
Weaving . .	Overlookers .	Male adults	26 2¾
	Warpers . .	Male and female adults .	19 4
	Weavers . .	Male and female adults, male and female non-adults, but chiefly females	12 10
	Dressers . .	Male adults	27 9½
Reeling . .	Reelers . .	Female adults and non-adults	7 11½
Roller-covering	Roller-coverers	Male and female adults .	18 4½
Attending the steam-engine and making machines	Engineers, firemen, mechanics, &c.	Male adults	21 8

If this table were combined with the relative numbers of each description of the hands, it would afford the absolute average of their earnings, but it is beyond a doubt that the average is not less than 10 shillings a week each person, young and old. It will be noticed that the lowest wages are given to the scavengers and piecers, who are generally young children. Out of a family of six persons there may be three, out of seven persons four employed at the factory, and when in a few years the children are become older, all may be so engaged. This will give for each of such families an average earning of 30*s.* or 40*s.* per week, when only three or four out of each family are employed, which would be amply sufficient to provide all the necessaries of life. The splendid gin-palaces, the numerous beer-houses in Manchester, make it but too obvious where the superfluous means of many go, and point out a source of demoralisation which is as frightful in its consequences as in its amount. But there are other signs which indicate anything but a want of means on the part of the great bulk of the population. The last Report of the Manchester and Salford District Provident Society shows that in 1837, though trade was not good, the amount received by its agents, who visit the houses of the work-people and take their savings in very small deposits, was 4735*l.*, while the Savings' Bank received within the year ending November, 1838, no less a sum than 109,123*l.* The following tables will furnish the reader with the means of judging how much of this came immediately from the operatives:—

Classification of Depositors, November 20, 1838.

The deposits stated as exceeding £30 since the eighth year, 1825, are not new deposits, but transferred by gift, decease, or otherwise, from old accounts to new acc

Not merely the factory hands, but generally all classes of working men have been in the receipt of wages sufficient, if well laid out, to procure all the necessaries and many of the comforts of life. Yet for want of the proper moral training, and by reason of the demoralising influence of Irish and other uneducated labourers, the abodes of a large proportion are wretched. Of 4102 dwellings, of which the Manchester Statistical Society gave a Report in 1834, founded on personal inspection, 3100 were houses, 752 cellars, 250 rooms; of these there were comfortable 1551, well furnished 689, not comfortable 255,1.

In 1838 the Society issued another Report of 28,186 dwellings examined.

Persons occupying	houses . . .	94,250
Do. do.	rooms of houses .	9,351
Do. do.	boarding with occupants of houses	9,671
		113,272
Persons occupying	cellars . . .	14,274
Do. do.	boarding with occupants of cellars	686
Total number of persons resident in the dwellings examined		128,232

Of the 28,186 dwellings, 14,042 are reported as ill-furnished and 8322 as not comfortable; thus only 72 per cent. of the houses of the working population of Manchester and Salford are comfortable. The Report adds, 'As in many (perhaps in the majority of cases) there are only *two* beds to a family of five or six persons of both sexes, the inconveniences and evils which must result are too obvious.'

The following is an extract from the Report for 1838 of the Manchester and Salford Town Mission, which, making allowance for the rhetoric of the style, affords a true picture of the condition of many: 'Those who only visit occasionally the dwellings of the poor can have no idea of the state of ignorance, superstition, demoralisation, and infidelity which exists. This is only to be discovered by those who visit them constantly and regularly, as our missionaries do. Scenes most disgusting and blasphemy at which the mind shudders are patiently borne and fearlessly met by the agency we employ. They (the town missionaries) have been stoned, threatened with death, surrounded with mobs, seriously bruised, and more than once they have narrowly escaped with their lives. And this in Manchester! Can it be supposed that the Christian public will suffer this state of things to exist without making a strenuous effort at once to meet the exigency of the case? Surely heathens at home should not be neglected.'

Schools and Scientific Institutions.— The education hitherto afforded to the working classes in Manchester has been very defective both in extent and quality. From the 'Report from the Select Committee on the Education of the Poorer Classes,' printed in 1838, much valuable information may be obtained. The Committee decided that daily education ought to be provided for one in eight of the population of a large town, and report that in Manchester only one in thirty-five is receiving an education likely to be useful. The numbers of children of the working classes stated to be at daily schools in the town are—at very indifferent day and dame schools 11,336; other better schools, 5680; total 17,100, on a population estimated at 200,000. The numbers attending Sunday-schools in Manchester are—under the Established Church 10,284, under Dissenters 19,032, Catholics 3812: respecting Sunday-schools the committee remark, 'They consider the instruction there given as of great advantage, by implanting feelings of religion and giving habits of order, but as imperfect without daily instruction also;' an opinion which will be thought not unfavourable by those who have personal experience of the workings, and therefore of the deficiencies, of these useful makeshifts, especially when they take into account the fact brought to light by Mr. J. Bentley by a personal examination, that in Manchester and Salford 1103 teachers and 11,479 scholars come too late to school, and this in the case of instruction where, the same authority informs us, the following is on the average all the time employed each Sabbath, that is, each week, namely, in reading about one hour and fifty minutes; in singing, fourteen minutes and twenty-one seconds; in praying, seventeen minutes and thirty-four seconds: total about two hours and a quarter. The educational clauses in the last Factory Act have been of but small advantage. Dr. Kay stated before the Education Committee of 1838, that one cause of failure was that no means were given in the Act for compelling the erection or provision of schools; and Mr. Ashworth stated from his own experience, 'If the manufacturer is desirous to make the most of the two hours, and give the children education, he may do some service in it, but a compulsory education affixed upon an employment is a stigma to the employment, and is very obnoxious to the employer, and, I think, generally people laugh at it; it is almost good for nothing.' In the Report of Mr. L. Horner on these very clauses (Feb., 1839), it is said—'Some parents appreciate the advantage (of the education), but most of them would much prefer their children working full time and earning a full rate of wages.' Under these circumstances it is easy to infer what good factory education confers. Indeed, Mr. Horner reports not more than eight mills in Manchester where 'the educational provisions have been best observed,' which 'best' he allows to be inferior to what primary education ought to be; and it embraces only 352 boys and 177 girls. The school of Messrs. M'Connel he considers worthy of special notice, and deserving of being held up as an example. He adds, 'It is not at all an unusual thing to have certificates (of education) presented to us subscribed by the teacher with his or her *mark*. In the last quarter I had a school voucher presented to me with a *mark*, and when I called on the schoolmaster to read it before me, he could not; I have had to reject the school voucher of the fireman (to the steam-engine), the children having been schooled in the coal-hole—in one case I actually found them there; it occurred at factories where a large capital must be embarked.'

Dr. Kay, before the Education Committee, gave in a table in which he calculated that in Manchester there was a total of uneducated and very ill-educated children of 26,265; that the actual cost of providing a worthless or indifferent education by existing methods was 15,021*l.* annually, and that not more than 19,500*l.* of annual outlay would be required for education, by an efficient method, of children now uneducated or very ill educated.

Meanwhile the diffusion of cheap literature and the operation of institutions for popular instruction are doing something to educate adults and youths, while the existence of a few good schools in Manchester for the children of the working classes will serve as models. In this way the 'Manchester Society for Promoting National Education' has rendered some service. It has at present three schools under its superintendence, with about 500 scholars.

Among the institutions in Manchester having an influence on the working classes there may be mentioned the Athenæum, the Mechanics' Institution in Cooper Street, the Mechanics' Institution in Miles-Platting, the Ancoats Lyceum, the Chorlton Lyceum, and the Parthenon. The Athenæum is designed for the benefit chiefly of clerks and other upper servants connected with the trade of the town. The experiment has been very successful. The number of subscriptions for the first quarter (1839) is upwards of 900. Lectures on various topics are given by men of eminence. There is a French class, an Italian class, an Amateur Musical Society, an Essay and Discussion Society; and concerts are occasionally given, which are very well attended. Connected with the Institution is a good library, a coffee-room, and a well-supplied news-room. Its expenditure is above 3000*l.* annually; James Heywood, Esq., is the president. The Mechanics' Institution, in Cooper Street, under the presidentship of Sir B. Heywood, Bart., has conferred great benefits on a class below those to whom reference has been made. The disbursements of the Institution during 1836 were 2177*l.* The original cost of the building was 6000*l.*, but as the institution had its resources mainly absorbed in defraying the annual charges, this sum has been increased by arrears of interest to 9570*l.*, and, deducting dividends paid, a balance is still due of 6105*l.*, to pay off which an effort is being made which gives promise of success. The number of subscribers on the 25th of December last was 1161, of whom 51 were under fourteen years of age, and 440 between fourteen and twenty-one. Sixty-five lectures were delivered during the last year, and were attended by 20,650 males, and 4800 females. Two concerts were also given. There are 5023 volumes in the library; the delivery of books to readers in the last year amounted to 62,451. The number of members in the respective classes were—grammar 128, German language 8, arithmetic 134, elocution and composition 28, mechanical drawing 64, landscape and figure drawing 46, music 24, writing 123, mathematics 18, French 25. Besides these there were the chemistry class, the mutual improvement society, and the natural history class. An exhibition of specimens of machinery, natural history, &c., on a very grand scale, to which 360 persons sent contributions, has been visited by nearly 100,000 persons, at the small charge of sixpence each. There is a reading-room, well furnished with literary and scientific periodicals. It is however to be regretted that the benefits of the establishment do not descend sufficiently low in the social scale, as the following classification of the numbers in 1837 will manifest:—

Principals, engaged as merchants, manufacturers, and mechanists	257
Mechanics, millwrights, and engineers	178
Overlookers, spinners, and other mill hands	36
Building trades	104
Sundry trades, chiefly handicraft	132
Warehousemen	204
Clerks	159
Artists, architects, engravers, &c.	62
Professional men	7
Schoolmasters	10
Shopkeepers and their assistants	82
No profession	41
Ladies	17
Youths	172
	1292

The knowledge of this fact, combined with a wish to reach the operative classes, has led to the establishment of the Lyceums in Ancoats and in Chorlton-on-Medlock, as well as of the Parthenon; and if we may judge from the first Report of that at Ancoats, which has just been issued, it is reasonable to hope that these institutions will confer immediate benefit on those who are employed in the factories and on other hand-labourers. The subscription is only two shillings a quarter, for which lectures, a library and reading-room, a selection of newspapers, education in classes, and other means of improvement, are provided. The education of females is made a prominent object. The news and reading rooms were opened on the 11th of October, 1838. From the library the average number of deliveries is 120 each evening. There are now on the books 732 members, of whom 240 are below twenty-one years of age; the 715 ordinary members are thus classified:—

Principals, engaged as merchants, manufacturers, and mechanists	10
Professional men	4
Schoolmasters	6
Shopkeepers, master-tradesmen, and their assistants	57
Warehousemen and bookkeepers	132
Mechanics, millwrights, engineers, moulders, and smiths	137
Engravers and pattern-designers	7
Spinners, weavers, and other mill-hands	102
Other trades connected with the manufactures of the town, as dyers, calico-printers, fustian-cutters, &c.	93
Building trades	37
Sundry handicraft trades	35
No profession	7
School-boys	22
Females	57
	715

The Manchester Free Grammar-School was founded by Hugh Oldham, bishop of Exeter. The foundation deed, bearing date 20th August, 1515, states the cause which influenced the founder to be that 'the youth, particularly in the county of Lancaster, had for a long time been in want of instruction, as well on account of the poverty of their parents as for want of some person who should instruct them.' And one of the fundamental requirements is, 'The high-master for the time being shall always appoint one of his scholars to instruct and teach in the one end of the school all infants that shall come there to learn their A B C, primer, and sorts, till they begin grammar.' These quotations show that the school was designed to furnish elementary as well as grammatical learning to the poor and those in need of instruction. The income of this school is now above 5000*l.* a year; and though its operations have been extended under a decree of the court of Chancery, and though the masters receive handsome salaries, the outlay must still leave an annual surplus. The instruction given comprehends the mathematics, the English and French, as well as the Greek and Latin languages; but the school is far from effecting the good which its splendid resources might produce, and cannot be considered as administered in a manner conformable to the donor's intention.

Chetham's Hospital, or *The College*, was founded by charter 1665, Humphrey Chetham being the benefactor, who, having during his life fed and brought up fourteen boys of Manchester and Salford, and of Droylsden, ordered in his will that the number should be augmented by the addition of one from Droylsden, two from Crumpsall, four from Turton, and ten from Bolton, leaving the interest of 7000*l.* for their maintenance and instruction from six to fourteen years of age, at which period they were to be put out to some trade. The scholars are instructed in reading, writing, grammar, and arithmetic. They are clothed, fed, boarded, and lodged. The school is conducted in a convenient old building, which also contains *the College library*, a fine collection of not less than 25,000 volumes, which have been accumulated out of the benefactions of the same H. Chetham: among the books are many rare and most valuable works. The library is open to the use of the public; books are not allowed to be taken out, but a convenient reading-room is provided. At present the good which this library does is but small, the delivery of books to readers not amounting to an average of twenty per day, a circumstance which may be explained by the fact of the library being only open at hours during the day when most persons are engaged.

Among the scientific institutions of the town, the Literary and Philosophical Society stands first in point of time (founded 1781). It has numbered among its members most of the distinguished natives of the vicinity, and many other persons of high reputation: its utility has been fully proved by the publication of its Transactions. The Royal Manchester Institution for the promotion of Literature, Science, and the Arts, formed mainly under the auspices of G. W. Wood, Esq., M.P. for Kendal, has been of service in furthering the diffusion of knowledge: above 30,000*l.* were laid out in the erection of the building. The Manchester Museum, or Natural History Society, which has a handsome hall in Peter Street, ranks among the most useful and interesting institutions of the town, and offers to the public a collection of objects in nature with which few similar establishments can enter into comparison. The council is empowered to open the museum to ladies, strangers, resident non-subscribers, schools, and the working classes.

In its medical schools Manchester has a claim on public esteem, having been the first provincial town to provide a good elementary medical education; and in its numerous and well-conducted medical institutions it possesses very superior advantages. The Infirmary is a school in itself. During the year 1838 its expenditure was 8125*l.* 5*s.* 8*d.*; from June, 1837, to June, 1838, it treated no less than 20,760 patients; and since its foundation, 1752, it has extended its benefits to 629,348 cases. There were in the house and on the books, June 24th, 1838, 1317 invalids. Of the cases treated in 1838, 13,254 were cured; 3584 were cases of accident. Messrs. Jordan and Turner have the honour of having taken the lead in the foundation of the medical schools, the one situated in Marsden Street, the other in Pine Street, in which about 140 pupils are conducted by able professors through a complete course of medical instruction. Manchester has also the advantage of possessing an admirable botanical garden, zoological gardens (recently opened, and affording much promise), a school of design, an architectural society, concert hall, choral society, &c.

Charitable Institutions.—These are too numerous to allow of more than a bare mention of some which are the most useful. The School for the Deaf and Dumb was founded in the year 1825. A new and handsome building for it has just been opened, situated near the botanical gardens, on the Stretford road, a part of which will be appropriated to a blind asylum also, under the will of Mr. Kershaw of Oldham, who bequeathed 20,000*l.* to be applied to the maintenance of an asylum for the blind, so soon as the inhabitants should furnish a suitable building. The Jubilee, or Ladies' Female Charity School, founded in 1806, is conducted in the house in Ducie-road, and educates forty girls for the duties of domestic service. The Manchester and Salford District Provident Society is designed to meet, by a special effort, the special wants of the poor. Following the impulse which Boston (U.S.), under the auspices of Dr. Tuckerman of that city, had given, the society sends forth visitors into all parts of the town (most of them are gratuitous labourers) to visit the poor at their own homes, aid them with advice, encourage them by sympathy, and receive their little savings in order to deposit them in the savings' bank. For this purpose the town is divided into districts and sections, in all 919, of which however 236 only are supplied with visitors. Its mendicity department effects no little good. Three thousand cases were examined by its stipendiary visitors in 1838, whereof 1285 received tickets to the various medical societies, 741 were referred to the relief board of the society, and 942 were found to be cases in which the society could not interfere. Besides these, 413 cases were sent for inquiry only, of which number 248 were reported as unworthy, a powerful argument against indiscriminate alms-giving. Work was found for 14 persons, and 98 new cases of gross imposition were detected and exposed. The ministry to the poor, which commenced Jan. 1833, under the patronage of three Unitarian congregations, namely, Cross Street, Mosley Street, and Greengate (Salford), is designed for a similar purpose with the Provident Society. It employs a paid agent, the Rev. G. Buckland, whose duties are not sectarian, but purely benevolent. His visits to the poor average per month about 340, and he has 500 families under his superintendence. Of a similar character is the Town Mission, whose motto is, 'Not to Proselyte, but to Evangelise.' Its expenditure during the last year was 1513*l.*, and the following is the result of the first year's exertions:—'Seventeen thousand eight hundred and thirty-seven hours have been spent by our missionaries in promoting the above objects. They have held eleven hundred and eighty-one meetings. They have paid forty-three thousand three hundred and sixty-seven visits; have lent six hundred and twenty-five Testaments, and distributed in their districts sixty-three thousand one hundred and sixty-two religious tracts. It is estimated that the number of individuals now under their care are at least sixty thousand. The number of visits paid to the sick are four thousand four hundred and eighty-three.' At present it occupies forty-two districts under a superintending missionary and three assistants. These districts contain from five to eight hundred families, about one-fifth of whom reside in cellars, and more than two-thirds of the whole seldom or never think of going to any place of worship. In several of the districts there are not quite twenty families for each house that is licensed for the sale of strong drink; and many of the districts have no place of worship of any kind save those in which the missionaries hold their meetings. It is a fact, well ascertained, that in many districts there are nearly as many reputed brothels as there are houses for the sale of strong drink.

Places of Worship.—The collegiate church is a noble Gothic building. The warden and four fellows have the ecclesiastical patronage of the parish. Their corporate income cannot be accurately stated, as they refused to give answers to a return of the value of their property, ordered by the House of Commons, but the ecclesiastical commissioners report the gross yearly income to be 4650*l.* The new see of Manchester will be in the province of York. [LANCASHIRE, p. 296.] In 1795, Aikin tells us, the number of churches and chapels of the Establishment in Manchester and Salford, actually built or building, amounted to twelve, and about as many places of worship for different sects of dissenters. There are now twenty-five places of worship in connexion with the Establishment, and above sixty in connexion with the dissenters in Manchester and Salford, of which the Wesleyan Methodists have twelve, the Independents eight, the Unitarians five, and the Roman Catholics four. The members of the Establishment in Manchester and Salford amount to 53 per cent. of the whole population. There are three cemeteries in Manchester, each of which has an officiating minister, one in Rusholme Lane, another at Ardwick, and the third at Collyhurst.

Eminent Persons.—Hugh Oldham, bishop of Exeter; John Bradford, put to death by Mary for heresy; Doctor John Dee, the astrologer; John Byrom, author of Byrom's shorthand, and of many small poems; Dr. Thomas Percival, an enlightened and benevolent physician; Dr. Henry, and the duke of Bridgewater, though not natives, are too much connected with the town to be passed without notice; and Dr. Dalton still survives to give lustre to a place on which he has conferred signal benefits. Crabtree, a native, ought also to be mentioned. [CRABTREE, WILLIAM.]

(*Communication from Manchester.* For further information see Whitaker's *History of Manchester*; Aikin's *Description of the Country from thirty to forty miles round Manchester*; Wheeler's *History, Antient and Modern, of Manchester*; *Reports*, &c.)

MANCHINEEL TREE. [HIPPOMANE MANCANILLA.]

MANCIPIUM, MANCIPATIO. The right apprehension of these terms is of some importance to those who study Roman authors. The following is the description of *Mancipatio* by Gaius (i. 119, &c.):—'Mancipatio is a kind of imaginary sale, and is a peculiar privilege of Roman citizens. It is effected in the following manner:—There must be present not fewer than five witnesses, Roman citizens, of full age, and also another person, of the same class and condition, to hold the brazen scales, who is called *libripens*. The person who receives *in mancipio*, taking hold of the thing, says, "I affirm that this man is my property, according to Quiritian Law, and I have purchased him with this money (aes) and these brazen scales." He then strikes the scales with the piece of money, and gives it to him from whom he receives *in mancipio* as the price. In this manner both slaves and free persons are mancipated, as well as animals, which belong to the class of things *mancipi*, or *mancupi*, such as oxen, horses, mules, asses; lands also (praedia), as well in the city as in the country, which are of the class *mancipi*, such as are the Italic lands, are mancipated in the same way. The mancipatio of lands differs from that of other things in this respect only, that persons, whether free or slaves, cannot be mancipated unless they are present, it being necessary that he who receives *in mancipio* should take hold of that which is given him *in mancipio*; whence in fact comes the term *mancipatio*, signifying that the thing is taken (capitur) by the hand (manu); but it is the practice to mancipate lands which are at a distance.'

In this passage Gaius describes generally what 'mancipatio' is, and, by implication, what things admit of 'mancipatio,' or, in other words, what things are 'mancipi.' He was led to these remarks by that part of the subject-matter of his text which treats of the rights of persons, or *status*; and he prefaces his description of 'mancipatio' by stating that all children who are in the power of their parents, and the wife who is in that peculiar relation to her husband when she is said *in manu viri esse* [MARRIAGE], are things *mancipi*, and may be mancipated in the same way as slaves. [EMANCIPATION.]

All things, as subjects of ownership, were either 'res mancipi' or 'res nec mancipi;' and there is, observes Gaius (ii. 18, &c.), 'a great difference between things "mancipi" and things "nec mancipi." The latter can be alienated by bare tradition or delivery, if they are things corporeal, and therefore susceptible of delivery. Thus the property in a garment, gold, or silver, may be transferred by bare tradition. Lands in the provinces may be transferred in the same way.' Thus 'mancipatio' was the proper term for expressing the sale or transfer of things 'mancipi,' and 'traditio' for expressing the transfer of things 'nec mancipi.' (Ulpian, *Frag.*, tit. 19.)

It appears then that the ownership of property generally which belonged to that class of things called 'res mancipi' could only be transferred by the formalities already described; but that the ownership of things which were 'res nec mancipi,' and among them, lands in the provinces, could be transferred without the formalities required in the case of 'res mancipi.' The foundation of the distinction as to lands appears to be this. The real ownership (dominium) of provincial lands was either in the Roman people, in which case the lands were called Stipendiaria; or in the reigning Caesar, in which case they were called Tributaria. There was therefore no ownership, properly so called, of lands in the provinces by individuals; at least no ownership in the sense in which lands in Italy were held. Lands in Italy held by individuals in full or Quiritarian ownership could be the subjects of usucapion, in jure cessio, mancipatio, and vindicatio; lands in the provinces could not, unless they acquired the Jus Italicum. Originally all the conquered lands even in Italy were Ager Publicus, the property of the state, and so long as they remained in that condition, nothing beyond the use (usus fructus) and occupation of them [POSSESSION] could be in private individuals. Much of the Ager Publicus in course of time was assigned to citizens in full ownership, and accordingly it would become 'mancipi' and subject to the same rule as to alienation as other lands held in Quiritarian ownership.

Mancipatio could only take place between Roman citizens and Latini Coloniarii and Latini Juniani, and those Peregrini who enjoyed the Commercium, or privilege of buying and selling. As the effect of Mancipatio was to transfer Quiritarian ownership with its accessory rights of usucapion, in jure cessio, mancipatio, and vindicatio, the reason of the rule is obvious. The form of mancipatio was in some respects a disadvantage, inasmuch as without observing the formalities required by the law, the *legal* property in a thing 'mancipi' could not pass. The mancipatio was that form of transfer of which we find similar examples in the early history of most countries, and implied originally an actual seisin of the thing transferred. No writing being required, it was necessary that there should be some evidence of the transfer, and such evidence was secured by the mode of transfer which the law required. So far as relates to land, mancipatio in its origin may be presumed to have been equivalent to the feoffment with livery of seisin. [FEOFFMENT.]

There was another mode of alienating things 'mancipi,' by the form called *in jure cessio*, which, according to Ulpian, was applicable also to things 'nec mancipi.' The *in jure cessio* was a fictitious action before a competent magistrate at Rome, as a praetor, or before a praeses in a province. The purchaser claimed the thing as his, and the seller either acknowledged his claim or made no defence, upon which the magistrate gave judgment for the purchaser. This form was in effect and was called 'legis actio.' (Gaius, ii. 24.) Its great resemblance to the fictitious suit formerly in use in our own system, called a Fine, might lead to the conjecture that the notion of a Fine was taken by the early practitioners in our courts from the Roman Law; and that this hypothesis is exceedingly probable will be the more apparent, the further any person examines into the connection between the early English and the Roman Law. The *in jure cessio* has apparently a closer resemblance to a Fine than the *transactio* of the Roman Law, to which some writers would refer as the origin of the Fine.

Mancipatio, as Gaius observes (ii. 25), was more in use than the *in jure cessio*, inasmuch as it was easier to transact the business with the assistance of a few friends than to go before a praetor, or a praeses.

Easements (*jura praediorum*, otherwise called *servitutes*) could be transferred in the case of lands in the city only by the *cessio in jure*; but in the case of lands in the country, also by *mancipatio*. But this observation applies only to Italic lands; in the provinces, rights of this kind, such as right of road, of conveying water, &c., were matter of contract.

Some difficulty has arisen from the use of the word *nexum*, or *nexus*, in connection with *mancipium*. '*Nexum*' properly signifies that which is bound or obligated, and hence it may signify the engagement or contract. Thus in the laws of the Twelve Tables, in the words, 'quum nexum faciet mancipiumque,' 'nexum' may signify the contract. Cicero (*Topica*, 5) defines 'Abalienatio' to be 'ejus rei quae mancipi est, aut traditio alteri nexu, aut in jure cessio, inter quos ea jure civili fieri possunt;' from which it follows that as there are only two ways of transferring the ownership of things 'mancipi,' and as the *in jure cessio* is here mentioned as one, the *nexus* must represent the other, that is, the *mancipatio*. The 'nexus' then in this case must be equivalent to the 'mancipatio,' or, as a more general term, must contain the mancipatio; for the mancipatio does not contain the nexum. This would be consistent with Varro (*De Ling. Lat.*, 6) quoting Manilius, who says that everything is 'nexum' which is transacted by the piece of money and scales (per aes et libram), which includes mancipium; but he adds that M. Scaevola considered 'nexum' to be everything transacted per aes et libram, so as to be thereby bound, *except* things which were transferred by mancipatio. Thus the definition of Scævola would exclude 'mancipatio' from the 'nexum,' but would include a testamentary disposition, inasmuch as that also was made per æs et libram (Gaius, ii. 103), and it would also include that form of marriage called *coemptio*. But if Scævola is right, and this can hardly be doubted, Cicero is wrong in the use of 'nexum,' in the passage quoted. In the 'Orator' (i. 39) he mentions both 'nexa' and 'mancipia' in his enumeration of the various subjects brought before the Centumviri. Assuming Scævola's definition to be correct, Cicero may have properly distinguished 'nexum' from 'mancipium' in the passage in the 'Orator;' and have used *nexu* with some inaccuracy in the passage from the 'Topica.'

MANCO CAPAC. [Peru.]

MANDAL. [Christiansand.]

MANDA'MUS is a writ by which the court of king's bench, in the name of the reigning king or queen, commands the party to whom it is addressed to do some act in the performance of which the prosecutor, or person who applies for or sues out the writ, has a legal interest; that is, not merely such an interest as would be recognised in a court of equity or in a court of ecclesiastical jurisdiction, but an interest cognizable in a court of common law; the right must also be one for the enforcing of which the prosecutor has no other specific legal remedy. Thus, a copyholder can transfer or alien his customary tenement or estate [Copyhold] in no other manner than by surrendering it into the hands of the lord of the manor to the use of the purchaser or surrenderee. The courts of common law formerly took no notice of the right of the surrenderee to call upon the lord for a grant or admittance, and the court of king's bench therefore left the party to seek his remedy in a court of equity, and would not interfere by granting a mandamus. But the obligation on the part of the lord to admit the surrenderee is not merely an equitable liability, because this mode of transferring property of this nature is founded upon antient custom, and rights dependent upon custom are matters of common-law cognizance. Of late years the court of king's bench appears to have taken this view of the subject, and has awarded writs of mandamus in all cases where the lord has refused to admit the party to whose use a surrender of the copyhold has been made. Again, the duty of parishioners to assemble in vestry for parochial objects, whether those objects be of a temporal or spiritual nature, is a common-law duty, and a mandamus will be granted to compel the parishioners to meet. But when they are met, the power of the court to interfere further by mandamus depends upon the nature of the act which the parishioners have to do. If the provisions of a statute are to be carried into execution, the act to be done, whatever its nature, is considered a temporal matter, because the construction of statutes belongs preeminently to the courts of common law. But if the object for which the vestry are assembled be one purely of ecclesiastical cognizance, as the setting up of bells, the purchase of books or vestments necessary for divine service, or the making provision for the repairs of the fabric of the church (delinquencies in which matters are punishable by interdict [Interdict] and ecclesiastical censures), the court of king's bench, being without judicial knowledge on such subjects, has no jurisdiction. It is probable indeed that ecclesiastical censures would formerly have been pronounced with less severity against the original delinquents than against those who should have attempted to bring such cases before a lay tribunal. Again, the court can by mandamus compel the visitor of an eleemosynary foundation to hear an appeal, but it has no further authority than 'to put the visitorial power in motion.' It cannot compel him to do any specific act as visitor.

The term 'mandamus' (we command) is found in a great variety of writs, and those usually distinguished by this name by the old law writers are totally different from the modern writ of mandamus, which appears to be nothing more than the antient 'writ of restitution' enlarged to embrace a great variety of objects, that writ being adapted merely to the purpose of restoring a party to an office from which he has been unjustly removed.

The writ of mandamus is now granted not only to restore a man to an office from which he has been wrongfully amoved, but also to admit to an office to which the party has been duly elected or appointed. It lies for a mayor, recorder, alderman, town-councillor, common-councilman, burgess, and town-clerk,—for a prebendary, master of a free-school, parish-clerk, sexton, and scavenger,—to hold a court-baron, court-leet, or a borough court of record,—to justices, to do an act within the scope of their authority, and which will not subject them to an action,—to restore a graduate in a university to degrees from which he has been suspended,—to a corporation, to pay poors-rates where they have not sufficient destrainable property,—to parish officers, to receive a deserted infant,—to permit inspection of documents of a public nature in which the party is interested,—to appoint overseers of the poor,—to swear in churchwardens,—to proceed to the election of a corporate officer,—to grant probate or letters of administration,—to affix the common seal to an answer agreed to by the majority of the members of a corporation aggregate,—and to allow a poor-rate, in which case the rule for a mandamus is absolute in the first instance.

The mandamus is said to be a prerogative writ; by which is meant,—either that the power to award it is not delegated by the crown to the ordinary judges between party and party, that is, the justices of the common pleas, but is reserved for that court in which the king is supposed to be personally present,—or that it is a writ of grace and favour, granted according to discretion, and not a writ of right, that is, not such a writ as the party applying for it has a right to call upon the court to issue under the clause of Magna Charta, by which the king binds himself not to refuse or delay justice or right.

In order to obtain a mandamus the applicant lays before the court the affidavit of himself or of others presenting the facts upon which his right and interest in the thing to be done, and his claim or title to the remedy, are founded. Upon this application the court, if it see a probable cause for interference, grants a rule calling upon the party against whom the writ is prayed, to show cause why such writ should not be awarded. At the appointed time the party so called upon either does not appear, in which case the rule is made absolute, and the mandamus is awarded as prayed, or he appears and resists the rule, either by insisting upon the insufficiency of the facts disclosed by the affidavits upon which the rule was obtained, or by producing other affidavits which give a different aspect to the transaction. If the resistance be effectual the rule is discharged; if not, the mandamus is awarded.

The writ, in the first instance, issues in an alternative form, requiring the party to do the act, or to show why he has not done it. The party may therefore make a return to the writ, saying that he has not done the act required for such and such reasons. Where the reasons returned are insufficient in law, the court quashes the return, and awards a peremptory mandamus requiring the party absolutely, and without allowing him any alternative, to do the act. Where the answer is apparently sufficient, the mandamus is at an end; and if the statements are untrue, the remedy is by action on the case for a false return, though in order to avoid expense and delay the party is allowed in some cases, by the statute 9 Anne, c. 20, and now in all cases, by 1 Will. IV., c. 21, to engraft an action upon the mandamus itself by traversing the return, *i.e.* by putting in a plea contradicting the allegations contained in such return. (Comyns's *Digest*; Selwyn's *Nisi Prius*; 1 Vict., c. 78.)

MANDARIN DUCK. [Duck, vol. ix., p. 185.]

MANDARINS is the general name of the officers of state in China. They are chosen from the men of letters or scholars from every part of the empire, who, having obtained their degrees and passed their examination, have their names inscribed in a register kept by a court or board established for this purpose. When an office in the administration is vacant, the court presents to the emperor a list of those who stand foremost on the register, from among whom the monarch appoints one to fill up the vacancy. Sometimes when there are several candidates equally qualified they draw lots for the vacant office. In Duhalde's time there were 13,600 mandarins all over the empire, independent of the military mandarins, or superior officers of the army. The civil mandarins are divided into nine classes, the highest of which, called 'Colaos,' are ministers of state, counsellors of the emperor, or presidents of the supreme courts. The governors of provinces rank in the second class. The secretaries of the emperor belong to the third class; the governors of cities to the fourth class, and so on. Each order has its distinctive mark of dignity; the highest orders wear a peacock's feather at the back of their caps. All is gradation and strict subordination among them.

MANDAVEE. [Cutch, vol. viii., p. 242.]

MANDELSLO. [Olearius.]

MANDEVILLE, SIR JOHN DE, was born at St. Albans, about the year 1300. He was descended from a family of distinction, and appears to have received a better education than was usual in those times. He studied mathematics, theology, and medicine, and for some years pursued the last as a profession. In 1327 he left England, passed through France, and proceeded to Palestine, where he joined the army of the infidels. He afterwards served in Egypt under the sultan, and in Northern China under the khan of Cathay. He resided for three years at the city of Peking, then called Cambalu, and appears to have travelled over a large part of Asia. After an absence of about thirty-three years, he returned to England, and wrote a narrative of his travels, which he dedicated to Edward III. He died on the 17th of November, 1372, at Liége, where he was buried.

His work contained details more ample and minute than any which had previously appeared concerning Palestine, Egypt, and parts of India and China, and must for some centuries have been an extremely interesting work. To render it more amusing, he seems to have borrowed unscrupulously from previous writers; he inserted parts of such chronicles as were then in existence, and introduced romantic tales of knight-errantry, miraculous legends, monsters, giants, and devils. Probably some of the most absurd parts of the work have been added or improved upon by the contemporary copyists.

His reputation as a traveller was very high in his own age. Besides a Latin version of his work, translations of it appeared in all the principal languages of Europe—in Italian, French, Spanish, and German. A MS. of Sir John Mandeville's travels, which belongs to the age of the author, is in the Cottonian Collection in the British Museum (Titus, C. xvi.). The first English edition was printed by Wynkyn de Worde, at Westminster, 8vo., 1499: 'A lytell Treatise or Booke, named John Maundevyll, Knyht, born in Englande, in the towne of Seynt Albone, and speaketh of the wayes of the Holy Lande toward *Jherusalem*, and of *Marvayles of Ynde* and other dyverse Countries.' The best English edition is that of London, 1725, 8vo., 'The Voiage and Travaile of Sir John Maundevile,' &c. Perhaps the first printed edition was that of Pietro de Cornero, Milan, 1480, 4to.: 'Tractato delle piu maravigliose Cosse e piu notabile che si trovano in le parte del mondo vedute … del Cavalier Johanne da Mandavilla.'

(*Biog. Univ.*; Watt's *Biblioth. Brit.*; *Manuel du Libraire.*)

MANDEVILLE, BERNARD DE, was born at Dort, in Holland, somewhere about the year 1670. He was brought up to the profession of medicine, and completed his studies and took the degree of Doctor of Medicine in Holland. He afterwards came over to England, to practise his profession in London. He does not appear to have had much success as a physician; but his writings assisted him in procuring the means of subsistence, while they also gained for him considerable notoriety. His first work was 'The Virgin Unmasked, or Female Dialogues betwixt an elderly maiden Lady and her Niece on several diverting Discourses on Love, Marriage, Memoirs, and Morals, &c.,' and was published in 1709. This is a work on a coarse subject, written in a coarse style. In 1714 Mandeville published a short poem, called 'The Grumbling Hive, or Knaves turned Honest,' to which he afterwards added long explanatory notes, and then published the whole under the new title of 'The Fable of the Bees.' This work, which is of an altogether superior character to the 'Virgin Unmasked,' and which, however erroneous may be its views of morals and of society, is written in a proper style, and bears all the marks of an honest and sincere inquiry on an important subject, exposed its author to much obloquy, and, besides meeting with many answers and attacks, was denounced as injurious to morality in a presentment of the Middlesex grand-jury, in 1723. It would appear that some of the hostility against this work, and against Mandeville generally, is to be traced to another publication, recommending the public licensing of stews, the matter and manner of which are certainly exceptionable, though it must at the same time be stated that Mandeville earnestly and with seeming sincerity recommends the plan as a means of diminishing immorality, and that he endeavoured, so far as lay in his power, by affixing a high price and in other ways to prevent the work from having a general circulation. Mandeville wrote also at this time in a paper called the 'London Journal,' which shared with the 'Fable of the Bees' the censure of the Middlesex grand-jury. He subsequently published a second part of the 'Fable of the Bees,' and several other works, among which are two, entitled 'Free Thoughts on Religion, the Church, and National Happiness,' and 'An Enquiry into the Origin of Honour and the Usefulness of Christianity in War.' We are told by Sir John Hawkins, in his 'Life of Dr. Johnson,' that Mandeville was partly supported by a pension from some Dutch merchants, and that he was much patronised by the first earl of Macclesfield, at whose table he was a a frequent guest. He died on the 21st of January, 1733, in his sixty-third year.

The 'Fable of the Bees, or Private Vices Public Benefits,' may be viewed in two ways, as a satire on man and as a theory of society and national prosperity. So far as it is a satire, it is sufficiently just and pleasant; but viewed in its more ambitious character of a theory of society, it is altogether worthless. It is Mandeville's object to show that national greatness depends on the prevalence of fraud and luxury; and for this purpose he supposes a 'vast hive of bees,' possessing in all respects institutions similar to those of men; he details the various frauds, similar to those among men, practised by bees one upon another in various professions; he shows how the wealth accumulated by means of these frauds is turned, through luxurious habits, to the good of others, who again practise their frauds upon the wealthy; and, having already assumed that wealth cannot be gotten without fraud and cannot exist without luxury, he assumes further that wealth is the only cause and criterion of national greatness. His hive of bees having thus become wealthy and great, he afterwards supposes a mutual jealousy of frauds to arise, and fraud to be by common consent dismissed; and he again assumes that wealth and luxury immediately disappear, and that the greatness of the society is gone. It is needless to point out inconsistencies and errors, such for instance as the absence of all distinction between luxury and vice, when the whole theory rests upon obviously false assumptions; and the long dissertations appended to the fable, however amusing and full of valuable remarks, contain no attempts to establish by proof the fundamental points of the theory.

In an 'Enquiry into the Origin of Moral Distinctions,' contained in the 'Fable of the Bees,' Mandeville contends that virtue and vice, and the feelings of moral approbation and disapprobation, have been created in man by their several governments, for the purpose of maintaining society and preserving their own power. Incredible as it seems that such a proposition as this should be seriously put forth, it is yet more so that it should come from one whose object always was, however strange the way in which he set about it, to promote good morals; for there is nothing in Mandeville's writings to warrant the belief that he sought to encourage vice.

MANDINGOES, a negro nation inhabiting the country on the banks of the rivers Senegal and Gambia, and that which extends farther eastward along the upper course of the Joliba or Quorra. This country occupies the northern declivity of the mountain-region which extends between the Gulf of Guinea and the great desert of the Sahara, and which goes under the name of Kong. [Kong.] The Mandingoes constitute a considerable portion of the population of most of the small kingdoms which occupy that extensive tract; in some of them they form a great majority; in others they live mingled with the Foolahs, Yaloffs, Sarawollis, Yarriba, and others. Their language seems to be more widely spread than any other that is spoken in that part of Africa, as Mungo Park, on his return from the interior, first heard the Mandingo language spoken to the west of Tallara and Jabbi on the Joliba, and found that it was understood as far west as Pisania on the Gambia, and even to Janjan-Bure or MacCarthy's Island (13° 33' N. lat. and 14° 45' W. long.).

The Mandingoes are distinguished among the negro tribes by their stature and some other characteristic features. They are generally above the middle size, well shaped, strong, and capable of enduring great labour. Their features are regular, their nose rather prominent, with the nostrils rather flattened; their lips are not so thick as in other negro tribes, but their hair is woolly. Their colour is a good clear black, inclining to yellow. Golberry thinks that the Mandingoes and the Foolahs, in the features of their face, more resemble the Hindus, or blacks of India, than the other negro tribes of Africa.

The Mandingoes in their writing use the Arabic characters, and are Mohammedans; but Golberry thinks that they have retained many of the usages of fetichism as practised on the coast of Guinea by the negroes. As their language is so widely spread over the western countries of Africa, Mr. R. Maxwell Macbrair, who is agent of the Wesleyan Missionary Society, has done good service in lately publishing a grammar and vocabulary of this tongue. The Gospel of St. Matthew has also been recently printed in Mandingo by the British and Foreign Bible Society from a translation by Mr. Macbrair.

The Mandingoes generally live on the produce of small spots of ground which they cultivate, and by the chace; but a considerable number apply themselves to commerce, and evince great shrewdness and activity in trade. Their habitations are mere hovels, but they make good coarse cloth of cotton, and dye it with indigo, a plant which is indigenous in their country: they have also attained some skill in tanning leather, and in smelting and working iron.

(Mungo Park's *Travels in the Interior of Africa;* Golberry's *Travels in Africa;* Washington's *Account of a Mandingo of Nyáni-Maru*, in *Lond. Geogr. Jour.*, vol. viii.)

MANDOLINE, a musical instrument of the lute kind, but smaller, having four strings, which are tuned as those of the violin. The mandoline is still met with occasionally in Italy, but has fallen into disuse in most other parts of Europe.

MANDORE, a musical instrument of four strings, of the lute kind, no longer in use under such name.

MANDRAKE. [ATROPA.]

MANDRILL. [BABOON, vol. iii., p. 231.]

MANDSHOO, a nation of Asia who originally inhabited the mountainous country which extends along the northern boundary-line of Corea as far north as the river Songari, an affluent of the Amur. The Mandshoo belong to a widely-spread race, which is generally known under the name of Tungooses. This race is found to the east of a line drawn from the most north-western angle of Corea to the Yalo Pass of the Khing-kan range (49° N. lat.), and thence through Nertskink to the northern extremity of the lake of Baikal, terminating on the shores of the Arctic Sea at the Bay of Katanga. From this line they spread eastward to a line drawn from Okhotzk to the mouth of the the river Lena. This race differs considerably from the Mongols, who inhabit the country farther west, in the form of their body, being tall and of a slender make. The languages of all the tribes of this race have a great similarity in words and construction; and it appears that there is a relationship between them and the language of the Mongols and Turks, as well as some languages of Eastern Europe, especially that of the Finlanders.

The Mandshoo, the most southern of the Tungoose tribes, have risen into great importance during the last two centuries by the conquest of China, and by seating their royal family on the imperial throne of Peking. They began their incursions into the northern provinces of the Celestial Empire about 1610. Their progress at first was slow, but it afterwards became so rapid, that in 1662 they proclaimed the son of their valiant chief Taytsong emperor of China, under the name of Kanghi, and he completed the conquest of the empire with singular success His family still occupies the throne of China. As the Mandshoo are a comparatively small tribe, and have to govern and to keep in subjection the immense population of China, the court of Peking has shown great political sagacity in adopting every means for incorporating the other Tungoose tribes into their own. All individuals belonging to these tribes are in China considered as native Mandshoos, and admitted to the privileges of the conquering nation. A great number of Tungoose families established in Siberia, on the eastern shores of the lake of Baikal, have accordingly abandoned that country, and emigrated to Mandshooria and China, where they serve as soldiers and attain military honours. The civil employments are reserved for the native Chinese, as they alone are acquainted with the manners, institutions, and laws of the country.

(Du Halde's *History of China;* Klaproth's *Asia Polyglotta;* Ritter's *Erdkunde von Asien*, vol. ii.)

MANDSHOORIA now constitutes a government of the Chinese empire under the name of Kirin-oola, or Ghirin-oola. It is the most eastern projection of the high lands of Central Asia, and lies between 42° and 58° N. lat., and between 120° and 142° E. long. Its surface is estimated at 650,000 or 750,000 square miles, which is more than triple the area of France. On the north it borders on Siberia, from which it is separated by a mountain-range, the Yablonoi Khrebet of the Russians, or the Khing-khan Tugwick of the Chinese. On the west it is divided from the Russian province of Da-uria by the river Kerlon, an affluent of the Amur, and from Mongolia by the river Khailar and the mountain-range called Khing-khan-oola. On the south it joins the Chinese provinces of Pe-cheli and Leao-tong, the latter of which formerly belonged to Mandshooria, and has only been detached from it since the present imperial dynasty ascended the throne of Peking. On the east is Corea, from which it is divided by the Tsi-yung-shan and Shan Alin, a high range; and farther north the Sea of Japan and the Gulf of Tartary, which separate the large island of Tarakai from Mandshooria.

A very small portion of the country has been visited by Europeans. The Jesuits who were sent by the emperor to survey the country visited the mountainous tract contiguous to the Tsi-yung-shan as far as Ninguta; and some Russian embassies traversed the country along the eastern declivity of the Khing-khan-oola. The remainder is almost entirely unknown.

Mandshooria may be considered as an immense valley enclosed by high and steep mountains, except at its south-western corner, where a broken and rather hilly tract divides it from the province of Leao-tong. The mountain-chain of the Khing-khan-oola, which forms the western boundary, seems to be the highest. Towards its southern extremity, between 42° and 43° N. lat., is the peak of Pe[illegible]a, which is thought to rise to more than 15,000 feet. There are other elevated and snow-capped summits farther north. The Yalo Pass, the only one traversed by Europeans, is near 49° N. lat., and even in April is covered with deep snow. The mountain-region of the Yablonoi Khrebet does not attain the snow-line; and its mean elevation probably does not exceed 2500 or 3000 feet above the sea-level. Along the Gulf of Tartary the coast is formed by an exceedingly steep mountain-range, rising to 4000 or 5000 feet, and coming close up to the sea, so that only a few level spots of inconsiderable extent intervene between the range and the water. On the eastern declivity of this range there is a tribe which seems to belong to the same race as the inhabitants of Japan: they are called Ainos or Kechen, and live on the produce of their fishing. This mountain-range seems to allow no passage, as the Ainos have no intercourse with the Mandshoo, who inhabit the country west of the range. At its southern extremity (43° N. lat.) this maritime range is probably connected with the Shan Alin and its continuation the Tsi-yung-shan, which appears to run in a south-south-west direction, until it terminates in the Hoang Hai, or Yellow Sea, in a long promontory, the most southern extremity of which is called the Regent's Sword. The huge mountain-mass of the Shan Alin rises above the snow-line.

The interior of Mandshooria contains, towards its southern extremity, an extensive and nearly level plain, called C[illegible]-chin. It lies on both sides of the Siren-Muren, or L[illegible] Ho, and seems to stretch northward to the banks of the rivers Nonni-oola and Songari. It greatly resembles the desert of the Gobi, which is only separated from it by the Khing-khan range, being mostly covered with sand, and having no water, or only salt lakes; but the grassy spots are more common and more extensive here than in the Gobi, and afford better pasture to the numerous cattle of the Mongols, who occupy this part of Mandshooria, which is also called the Eastern Gobi. In some parts the surface is covered with salt incrustations. The remainder of Mandshooria is supposed to consist of a succession of valleys and mountain-ranges of various elevation. The mountains however are not bare, but covered with forests nearly to the top. The valleys are said to be fertile, and wide along the principal rivers south of the Amur river, and so far it appears that agriculture extends. But that large part of the country which extends from the last-mentioned river to the Yablonoi Khrebet is too cold for agriculture, and its inhabitants live on the produce of their herds and of the chase.

Though the climate of Mandshooria is not equal in severity to that of the Gobi, it must be very cold, as we may infer from its geographical position and its elevation.

The principal river is the Amur, which has numerous tributaries. [Amur.] Through the southern districts runs the Sira-Muren, or Liao-Ho, which flows about 500 miles; it rises in the Khing-Khan range north of the Peak of Pe-cha, and runs for nearly 200 miles east, and the remainder of its course south-west, until it falls into the Gulf of Liao-tong. It seems to be navigated nearly up to the place where it turns to the south-west.

Agriculture is common south of the river Amur. Wheat, rye, barley, and buckwheat are cultivated extensively, as well as hemp and millet. The forests, which cover the greatest part of the surface, are partly composed of oak and lime-trees, and partly of different kinds of pines, fir, and larch. On the mountains towards Corea the rhubarb and the ginseng grow in abundance; both are collected by the natives, and constitute, with furs, the principal articles of export. All domestic animals common in the countries of central Europe are kept in considerable numbers; there are also reindeer in the districts north of the Amur, and camels in many places south of it. Wild animals are numerous, especially those that yield furs, in the forests which clothe the eastern declivity of the Khing-khan, where sables, ermines, bears, wolves, and foxes are found. Among the wild animals peculiar to this and the neighbouring countries are the argali and the dshiggetai. Fish abound in the rivers, especially the sturgeon and salmon. Pearls are said to be found in some of the streams. The mineral riches of Mandshouria are not known.

The population is very vaguely estimated at two millions, but it is probably much underrated. All the people, with the exception of the Mongols, who inhabit Chalcha, belong to the race of the Tongouses. [Mandshoo.] The most widely spread tribe is the Proper Tungooses, who seem to occupy the whole or nearly the whole country north of the Amur, and also the greatest part of that between the Nonni-oola and Songari rivers. They lead in general a nomadic life, subsisting on their herds of cattle or reindeer. The Tagurri, or Da-uros live on the river Nonni, and are agriculturists. Among them are settled the Yakutes, about 2000 families, which emigrated in 1757 from Siberia. The Mandshoo occupy the south-eastern part of the country; though not the most numerous of the tribes, they are the most important, their sovereign family having ascended the throne of China. [Mandshoo.] They are agriculturists, but pass a great part of their life in hunting. Many Chinese families have settled among them, and have improved their modes of cultivation.

The governor of the province resides at Chirin-oola, a place of some importance. Ningouta, on the Hurka Pira, an affluent of the Songari river, is the ancient residence of the chiefs of the Mandshoo, and is held in great veneration by the court of Peking and the whole nation. Other towns of some importance are Naun-hoton, on the Nonni, and Sikhalien, on the Amur.

(Du Halde's *History of China*; Broughton's *Voyage of Discovery in the Northern Portion of the Pacific Ocean*; La Pérouse's *Voyage round the World*; Ritter's *Erdkunde von Asien*, vol. 1.)

MANES, the name given by the Romans to souls separated from the body. According to Apuleius (*De Deo Socrat.*) they were originally called lemures, and were divided into two kinds, lares and larvae; the former being the souls of such persons as had lived virtuous lives, and the latter of such as had been wicked; but that afterwards the name of manes was applied to both. Augustine (*De Civ. Dei*, ix. 11) gives a somewhat different account; he says that the souls of good men became lares, those of evil men lemures or larvae, and those respecting whom it was uncertain whether their virtues or vices most predominated, manes. According to these accounts, and to a passage in Virgil (*Æn.*, ix. 255-6), the lares were considered by the Romans as the manes of their ancestors.

The etymology of manes is uncertain; it is generally derived, by ancient grammarians, from an old word *manus*, signifying 'good,' probably in the same sense as the Furies were called *Eumenides* by the Greeks. Some considered the manes as the good and bad genii which accompanied a man through his life; but this notion appears to have been introduced by the later Platonists.

The stones in the Roman burial-places and their funeral urns were generally inscribed with the letters D. M. S., that is, *Dis Manibus Sacrum*, 'Sacred to the Manes Gods.' There are many specimens of such funeral inscriptions in the [illegible] Gallery, British Museum. The term 'gods,' applied to the manes, would appear to imply a kind of deification of departed souls. If such is the fact, it would be a curious matter of inquiry to ascertain when the manes were first honoured with the style of "dei" or "gods." The things which were left or belonged to the Dii Manes were Religiosae; those consecrated to the Dii Superi were called Sacrae. (Gaius, ii. 4.)

It was the duty of the Pontifex Maximus to see that the manes were propitiated by proper ceremonies (Liv., i. 20), and with this object it was usual to pour libations of wine on the funeral pile, and also sometimes to slaughter animals, especially such as the deceased had been fond of. (Plin., *Ep.*, iv. 2.)

MA'NETHO (Μανέθων, Μανεθῶ, Μανεθὼς, or Μανεθῶς), a celebrated Egyptian writer, a native of Diospolis, who is said to have lived in the time of Ptolemy Philadelphus at Mendes or Heliopolis, and to have been a man of great learning and wisdom. (Ælian, *De Animal.*, x. 16.) He belonged to the priest caste, and was himself a priest, and interpreter or recorder of religious usages and of the religious and probably also historical writings (ἱερογραμματεύς). It appears probable however that there were more than one individual of this name; and it is therefore doubtful whether all the works which were attributed by ancient writers to Manetho were in reality written by the Manetho who lived in the reign of Ptolemy Philadelphus.

The only work of Manetho which has come down to us complete is a poem, in six books, in hexameter verse, on the influence of the stars (Ἀποτελεσματικά), which was first published by Gronovius, Leyden, 1698, and has also been edited by Axtius and Rigler, Cologne, 1832. It is probable however, for many reasons, as Heyne has shown in his 'Opuscula Academica' (vol. i., p. 95), that parts at least of this poem could not have been written till a much later date. We also possess considerable fragments of a work of Manetho on the history of the ancient kings of Egypt, which there is every reason for supposing was written by the Manetho who lived under Ptolemy Philadelphus. It was in three books or parts, and comprised the period from the earliest times to the death of the last Persian Darius. Considerable fragments are preserved in the treatise of Josephus against Apion; and still greater portions in the 'Chronicles' of George Syncellus, a monk of the ninth century. The 'Chronicles' of Syncellus were principally compiled from the 'Chronicles' of Julius Africanus and Eusebius, bishop of Cæsarea, both of whom made great use of Manetho's 'History.' The work of Africanus is lost, and we only possess a Latin version of that of Eusebius, which was translated out of the Armenian version of the Greek text preserved at Constantinople. Manetho derived his history of the kings of Egypt, which he divides into 30 classes, called dynasties, from the sacred records in the temple at Heliopolis.

In addition to these works, Manetho is also said to have written:—1, Ἱερὰ βίβλος, on the Egyptian religion; 2, Βίβλος τῆς Σώθεως, the subject of which is doubtful; 3, Περὶ ἀρχαϊσμοῦ καὶ εὐσεβείας, on the ancient rites and ceremonies of the Egyptians; 4, Φυσικῶν ἐπιτομή (Laert. *Proœm.*, s. 10), probably the same work as that called by Suidas φυσιολογικά.

It is no easy matter to ascertain the real value of Manetho's 'History' in the form in which it has come down to us. The reader may judge of the use that has been made of it for Egyptian chronology by referring to Rask's *Die Aegyptische Zeitrechnung* (Altona, 1830), to the works of Champollion, Wilkinson's *Topography of Thebes*, and the other authorities which will be indicated by a reference to those works.

(Fabricii *Bibliotheca Græca*, ed. Harles, vol. iv., p. 128-135; the *Preface* of Axtius and Rigler; and *Egyptian Antiquities*, in the 'Library of Entertaining Knowledge,' vol. i., p. 96, 97.)

MANETTIA CORDIFO'LIA is a Brazilian twining plant, whose roots possess considerable emetic energy. The bark is administered in Brazil in powder, in doses of ½ to 1½ drachms, and is considered a most valuable remedy in dropsy and dysentery. (Lindley's *Flora Medica*, No. 892, p. [illegible].)

MANFELOUT. [Egypt.]

MANFRE'DI, natural son of the emperor Frederic II. and of a Lombard lady, was appointed by his father, at his death, A.D. 1250, regent of the kingdom of the two Sicilies, until the arrival of his brother Conrad, the legitimate son and heir of Frederic. Pope Innocent IV. excommunicated Manfred, and declared that the dynasty of Suabia had forfeited the crown of Sicily in consequence of Frederic having revolted against the see of Rome, whose feudatory he was. Upon this, most of the towns of Apulia revolted against the authority of Manfred. Conrad however came with an army from Germany, and soon reduced the rebels, but he died in the midst of his successes, in 1254, leaving an only son in Germany, Corradino, then a child two years old. Manfred became again regent of the kingdom in the name of his nephew, and as such had to carry on the war against the pope and his own revolted subjects, among whom the powerful baronial house of San Severino stood foremost. The city of Naples opened its gates to the pope and swore allegiance to him; but Manfred found refuge among his father's faithful Saracens at Lucera. Upon the death of Innocent, which took place soon after, Manfred recovered possession of Naples, and cleared the kingdom of the invaders. A report being spread that Corradino had died in Germany, the barons, prelates, and towns of the kingdom invited Manfred to ascend the throne, and he was crowned at Palermo in 1258. On his return to Apulia, he found messengers from Margaret, Corradino's mother, who informed him that his nephew was still alive, and they claimed his inheritance in his name. Manfred refused to resign the crown, but declared in the presence of the envoys that as he had no male issue, the crown should at his death devolve on his nephew or his nephew's heirs. No one presumed to gainsay Manfred's words? he was brave, high spirited, and handsome, and the idol of the people. He had just delivered the country from the invaders, and his illegitimate birth was no longer remembered. Margaret herself tacitly assented to his retaining the crown upon such conditions: her son was but a boy, and had a fair prospect of succeeding his uncle in due time. To crown Manfred's good fortune, Pope Alexander IV. made peace with him. Manfred was now looked upon as the hereditary protector of the Guibelines of North Italy, and he sent troops to the assistance of those of Tuscany, who defeated the Guelphs at Monteaperto, and occupied Florence. In 1261 Alexander IV. died, and was succeeded by Urban IV., an inveterate enemy of the Guibelines and of the House of Suabia. The new pope began by excommunicating Manfred, treating him as a usurper, and offering the crown of Sicily for sale among the princes of Europe. He offered it to Richard, earl of Cornwall, brother to Henry III. of England, who laughed at the proposal, and said 'it was like making him a present of the moon.' Urban then offered the crown of Sicily to Henry himself for his second son Edmund, but the English king had neither troops nor money to enforce such a claim. At last the pope addressed himself to Charles, count of Anjou, brother of Louis IX. of France, who accepted the offer in 1264: the conditions were, that he should receive the crown of Sicily as a fief of the see of Rome, pay a yearly fee of a thousand ounces of gold and a white horse, surrender to the pope the right of nominating to all the sees of the kingdom, and grant an appeal to Rome on all ecclesiastical affairs. After concluding this bargain, Urban died, but his successor Clement IV. followed up his policy. Charles, having collected an army of his Provençal vassals and of French adventurers, came to Rome, where he was solemnly crowned by Clement in 1265. In January, 1266, he marched from Rome, and entered the dominions of Manfred, who met him under the walls of Benevento. A desperate battle took place in the month of February. Manfred's faithful Saracens fought bravely, but being unsupported by the Apulian troops, who refused to advance, they were thrown into disorder, and Manfred, seeing himself betrayed, spurred his horse into the thickest of the enemy's ranks, and fell under a heap of the slain. His body was buried by Charles's soldiers, without any honours, under a heap of stones on the banks of the river Calore, but the papal legate ordered it to be disinterred, because, being excommunicated, it could not remain within ground belonging to the holy see. The body was dragged as far as the frontiers of Abruzzo, where it was allowed to rest on the banks of the river Verde, an affluent of the Tronto, near Ascoli. Dante, in pathetic and at the same time indignant strains, alludes to this disgraceful act of fanaticism ('Purgatorio,' canto iii.).

Manfred was fond of letters, was himself a poet, and is praised by the Neapolitan chroniclers for his great and noble qualities. The Guelph writers, on the contrary, have accused him of horrid crimes; among others, of poisoning and incest. This tradition has preserved the remembrance of him as a dark and mysterious character. Manfred was the founder of the town of Manfredonia.

MANFREDO'NIA. [CAPITANATA.]

MANGABEY, a name for two species of monkeys belonging to the group of *Guenons*. [GUENONS.]

MANGALORE. [HINDUSTAN, p. 207.]

MANGANESE, a metal of which the black oxide, or binoxide, was first described by Scheele in 1774, and was afterwards determined by him and Gahn to contain a peculiar metal, which has so powerful an affinity for oxygen, that this circumstance alone would prevent its occurrence in nature in its metallic state. The natural compounds of manganese, and especially its oxides, are numerous, and are found abundantly in many parts of the earth. Like oxide of iron, it frequently occurs in minerals in such small quantity as to show that it exists in them rather in mixture than combination.

Manganese may be procured by mixing any of its oxides with oil, and heating it strongly in a well covered crucible. Its properties are, that it has a greyish-white colour and resembles white cast-iron in appearance; it is hard, brittle, and has a fasciculated crystalline structure; its specific gravity, according to Berthier, is 7·05; it is inodorous and tasteless, but when breathed upon emits a smell of hydrogen gas. By exposure to the air manganese readily tarnishes by oxidizement, and even in a very short time attracts sufficient oxygen to lose its metallic lustre, and falls to a reddish-brown powder; hence the necessity for preserving it immersed in naphtha. Even at common temperatures it slowly decomposes water; and at a red heat the decomposition is rapidly effected, and in both cases hydrogen gas is evolved and oxide of manganese formed. It requires an extremely high temperature for its fusion, and it is fixed in the fire.

The ores of manganese are chiefly oxides: they are the following:—

Haussmannite.—Occurs crystallized in octohedrons and massive. Primary form a square prism. Cleavage parallel to the base of the primary form. Fracture uneven. Hardness rather greater than that of phosphate of lime. Colour brownish-black. Powder reddish-brown. Lustre imperfect metallic. Opaque. Specific gravity 4·722.

Before the blow-pipe with borax fuses into an amethystine-coloured glass. It is found at Ilmenau in Thuringia, at Framont, and in Pennsylvania, &c.

Dr. Turner's analysis gives very nearly—

Manganese . . .	70·98
Oxygen . . .	27·38
Silica . . .	0·34
Barytes . . .	0·11
Water	0·43
	99·19

The equivalent of manganese being 28, this ore is essentially a compound of 3 equivalents of metal 84 + 4 equivalents of oxygen 32 = 116. It contains less oxygen than any other oxide except the protoxide, which does not occur in nature except in combination.

Braunite.—Occurs crystallized and massive. Primary form a square prism. Cleavage distinct, parallel to the faces of an octohedron. Fracture uneven. Hardness 6·0 to 6·5. Brittle. Colour brownish-black. Streak the same. Lustre imperfect metallic. Opaque. Specific gravity 4·818. The massive varieties are divergingly fibrous.

Before the blow-pipe melts and effervesces slightly with borax.

It is found at Elgenberg, Wursindel, Piedmont, and in Cornwall.

According to Dr. Turner, it consists very nearly of—

Manganese . . .	67·76
Oxygen . . .	29·03
Barytes . . .	2·26
Water	0·95
	100·

It is essentially an anhydrous sesquioxide of manganese, consisting of 1 equivalent of metal 28 + 1½ equivalent of oxygen 12 = 40.

Manganite.—Occurs crystallized and massive. Primary form a right rhombic prism. Cleavage parallel to the lateral faces. Fracture uneven. Hardness 4·0 to 4·25. Scratches glass slightly. Colour iron and steel, and blackish grey. Streak reddish-brown. Lustre metallic. Opaque. Specific gravity 4·328. Massive varieties amorphous. Structure crystalline granular, large fibrous.

Before the blow-pipe, with borax, fuses into a transparent amethystine glass; heated in a tube, water is expelled. It occurs at Hartshill near Coventry, in Devonshire, Ilfeld in the Harz, &c.

Dr. Turner's analysis gives very nearly—

Manganese . . .	62·93
Oxygen . . .	26·97
Water	10·10
	100·

It is therefore hydrated sesquioxide of manganese.

Varvacite.—Occurs massive and in pseudo-crystals. Composed of thin plates and fibres. Hardness 2·5. Colour grey. Powder black. Lustre metallic. Opaque. Specific gravity 4·531. When strongly heated yields oxygen gas and water.

It occurs massive at Hartshill in the county of Warwick, and the pseudo-crystals at Ilfeld.

Analysis according to Phillips—

Manganese . . .	63·1
Oxygen	31·5
Water	5·4
	100·

It is a compound of 4 equivalents of metal 112 + 7 equivalents of oxygen 56 and 1 equivalent of water 9.

Pyrolusite.—Occurs crystallised and massive. Primary form a right rhombic prism. Cleavage parallel to the lateral planes and short diagonal; indistinct. Fracture uneven. Hardness 2·0 to 2·5. Colour blackish-grey and black. Streak black. Lustre imperfect metallic. Opaque. Specific gravity 4·94.

Massive varieties amorphous, reniform, and botryoidal. Structure granular, fibrous.

It is the most abundant ore of manganese, occurring in large quantity in Devonshire, Warwickshire, Thuringia, Brazil, and many other places.

Dr. Turner's analysis gives very nearly—

Manganese . . .	61·95
Oxygen . . .	35·50
Silica	0·50
Baryta . . .	0·66
Water	1·39
	100·

It is a compound of 1 equivalent of metal 28 + 2 equivalents of oxygen 16 = 44, and is the per- or binoxide.

Hydrated Binoxide of Manganese has long been known by the name of *black wad.*—It occurs of various shades of brown, and is massive, botryoidal, amorphous, and sometimes pulverulent. It is frequently soft enough to soil the fingers. It occurs largely in Devonshire, and is also met with in Cornwall, the Harz, Piedmont, and many other places.

Analysis of a specimen from the Harz by Klaproth—

Peroxide of Manganese .	68
Oxide of Iron . . .	6·5
Water	17·5
Silica and Baryta . .	8·
Carbon	1
	101

Psilomelane is an ore of manganese which contains a considerable quantity of baryta. It occurs reniform, botryoidal, and stalactitic. Structure granular, compact, and indistinctly fibrous. Fracture conchoidal, even. Hardness 5·0 to 6·0. Colour dark-grey and greyish-black. Streak brownish-black. Lustre imperfect metallic. Opaque. Specific gravity 4·0 to 4·15. It occurs in Devonshire, Cornwall, in the Harz, and most manganese mines.

Dr. Turner's analysis gives—

Red oxide of Manganese	69·795
Oxygen . . .	7·364
Baryta . . .	16·365
Water . . .	6·216
Silica	0·260
	100·

Sulphur is also found in combination with manganese. The compound is called

Alabandite, Manganese Blende, &c.—It occurs crystallised and massive. Primary form a cube. Cleavage parallel to its faces. Fracture uneven, conchoidal. Hardness 3·5 to 4·0. Colour brownish-black; when fresh fractured, steel-grey. Streak dark-green. Lustre imperfect metallic. Opaque. Specific gravity 4·014.

Fuses with difficulty and only the edges with the blowpipe; gives sulphuretted hydrogen when dissolved in an acid.

It is found at Nagyag in Transylvania, and in Mexico.

Analysis by Arfwedson—

Manganese . . .	62·
Sulphur . . .	37·6
	99·6

Manganese occurs also in combination with some metals and oxides.

Arseniuret of Manganese.—Occurs massive. Fracture in one direction granular and shining, in the other dull. Structure foliated. Hard. Brittle. Specific gravity 5·55. Found in Saxony. Colour whitish-grey. Blackens by exposure to the air.

Dr. Kane found it to consist of—

Manganese . . .	45·5
Arsenic with a trace of Iron	51·8
	97·3

Cupreous Manganese.—Occurs massive, reniform and botryoidal. Structure compact. Fracture imperfect conchoidal. Hardness about 1·5. Colour bluish-black. Streak the same. Lustre resinous. Opaque. Specific gravity about 3·2.

Occurs in Bohemia and Chili.

Analysis by Kersten—

Oxide of manganese .	74·10
Oxide of copper . .	4·80
Water	20·10
Sulphate of lime . .	1·05
Silica	0·30
	100·35

Carbonic acid and silica also occur in combination with oxide of manganese, and the latter also with oxide of manganese and iron.

Carbonate of Manganese: Diallogite.—Occurs crystallised and massive. Primary form a rhomboid. Cleavage parallel to the primary planes. Fracture uneven, conchoidal. Hardness 3·5. Colour rose-red, brownish. Streak white. Translucent. Lustre vitreous, pearly. Specific gravity 3·3 to 3·6. Massive varieties globular, botryoidal. Structure compact, fibrous, granular. Colour yellowish-white. Opaque.

Found at Hartshill in Warwickshire, Nagyag, Freyberg, &c.

Analysis of the carbonate from Nagyag by Berthier—

Carbonic acid . . .	38·6
Protoxide of manganese .	56·0
Lime	5·4
	100·

Silicate of Manganese.—Occurs crystallised and massive. Primary form an oblique rhombic prism. Cleavage parallel to the lateral faces of the primary crystal. Fracture uneven and conchoidal. Scratches glass. Colour rose-red. Translucent on the edges. Lustre between pearly and resinous. Specific gravity 3·538 to 3·685.

It occurs in Sweden, the Harz, Devonshire, Cornwall, &c.

Analysis by Berzelius—

Silica	48·
Oxide of manganese .	49·04
Lime and magnesia .	3·24
	100·28

Leonhard has described some silicates of manganese under the names of *allagite, photizite, rhodonite,* &c., which contain admixtures of various other substances.

Silicate of Manganese and Iron · Knebelite.—The locality of this is not known. It occurs massive. Externally cellular and uneven. Fracture imperfect conchoidal. Lustre glistening. Colour grey; spotted dirty-white, red, brown, and green. It is opaque, hard, and brittle. Specific gravity 3·714.

Analysis by Döbereiner—

Silica	32·5
Protoxide of manganese .	35
Protoxide of iron . .	32
	99·5

Phosphate of Manganese and Iron: Ullmannite.—Occurs massive. Fracture conchoidal. Hardness 5·0 to 5·5. Colour reddish-brown, or blackish. Lustre resinous. Opaque. Specific gravity 3·439 to 3·775.

Occurs at Limoges in France.

Analysis by Berzelius—

Phosphoric acid . .	32·8
Oxide of manganese .	32·6
Oxide of iron . . .	31·9
Phosphate of lime . .	3·2
	100·5

Two other varieties have been described under the name of *Heteposite* and *Huraulite.*

Having now noticed the more important manganese ores, we proceed to mention the action of other elementary bodies upon this metal, and first the artificial compounds of—

Oxygen and Manganese.—It has been already mentioned that this metal falls to powder by oxidation, even by exposure to the air, and the oxide thus formed appears to be the red oxide of manganese: the native compound has been already described under the name of haussmannite. The protoxide of manganese exists in nature only in combination, forming the carbonate of manganese, also mentioned.

Protoxide of Manganese may be artificially procured in two or three ways:—1st. When the peroxide of manganese is strongly heated in an iron retort for the purpose of obtaining oxygen gas, green protoxide of manganese will sometimes remain, though it is in general the red oxide which is thus obtained; 2nd. The protoxide may be obtained by passing hydrogen gas over any higher oxide, but the red is to be preferred as containing the least oxygen; 3rd, by mixing chloride of manganese with twice its weight of carbonate of soda, and heating the mixture in a platina crucible, and afterwards dissolving out the chloride of sodium formed with water.

The properties of protoxide of manganese are:—It is of a light green colour. It undergoes no change by exposure to the air. It is insoluble in water. When heated to 600° it acquires oxygen, and is converted into red oxide; and sometimes, by exposure to a strong heat, it undergoes combustion as well as oxidation. It combines readily with acids, and dissolves in them, even when dilute and cold, without effervescence; and the solutions are colourless. It is this oxide which is the base of all the common salts of manganese; indeed it is questionable whether any other oxide acts as a base. When this oxide is precipitated from solution by an alkali, it forms a white hydrate, which speedily loses water and acquires oxygen by exposure to the air, and becomes deutoxide. It is composed of—

One equivalent of oxygen . .	8
One „ manganese . .	28
Equivalent	36

Red Oxide of Manganese: Haussmannite, already described.—It is artificially obtained by submitting either the protoxide, sesquioxide, or peroxide of manganese to heat in a platina crucible; the first acquires and the two last lose oxygen by this process; in fact, whatever oxide or salt of manganese is strongly heated, it is decomposed and converted into this, and remains permanently such unless some additional deoxidizing agent be employed. It suffers no change by exposure to the air, is insoluble in water, and has a reddish colour. The nitric, sulphuric, and hydrochloric acids all decompose it, the two first separating it into protoxide and binoxide; and they dissolve the first and leave the second insoluble. With hydrochloric acid it yields a chloride and chlorine.

It is composed of—

Four equivalents of oxygen . .	32 or	10·66,	1⅓ eq.
Three equivalents of manganese	84	28	1 eq.
Equivalent	116	38·66	

Sesquioxide, Deutoxide of Manganese.—The native has been described under the name of manganite. It may be artificially procured in the mode just alluded to, by decomposing a protosalt with an alkali, and exposing the precipitate to the air, or by cautiously heating the peroxide or carbonate of manganese: in the former case oxygen is expelled, and in the latter carbonic acid is expelled and oxygen absorbed; it may further be obtained by decomposing the nitrate with heat. Its properties are:—It is brown, except when obtained from the nitrate, and then it is nearly black. It is insoluble in water, suffers no change by exposure to the air, is decomposed by dilute nitric and sulphuric acids, being separated by them into protoxide, which they dissolve, and peroxide, which remains insoluble. It is said to be soluble in strong sulphuric acid without decomposition; with hydrochloric acid it yields chlorine and chloride of manganese.

It is composed of—

One and a half equivalent of oxygen .	12
One equivalent of manganese . .	28
Equivalent	40

Varvicite.—This has not been obtained by artificial means.

Binoxide or Peroxide of Manganese: Pyrolusite.—This may be formed artificially by decomposing either the red oxide, sesquioxide, or varvicite by means of dilute sulphuric acid, they being all separated into protoxide, which dissolves, and binoxide, which remains insoluble. It may also be prepared by adding chloride of lime to a solution of chloride of manganese, in which case it is thrown down in the state of a black powder.

Its properties are:—It is black, or brownish-black, unalterable in the air, insoluble in water, decomposed by heat into red oxide and oxygen gas, insoluble in alkalis, unacted upon by nitric acid or dilute sulphuric; but by the last acid, when concentrated, resolved into protoxide and oxygen gas; and is thus sometimes used for preparing the protosulphate and oxygen. With hydrochloric acid it gives protochloride and chlorine.

It is composed of—

Two equivalents of oxygen . .	16
One equivalent of manganese . .	28
Equivalent	44

Of the five oxides of manganese it will appear that three are resolvable, by the action of dilute sulphuric acid, into definite compounds of the protoxide and binoxide, thus:—

	Oxygen.		Metal.		Protoxide.		Binoxide.
One equiv. of sesquioxide =	3	+	2	=	1	+	1
„ „ red oxide =	4	+	3	=	2	+	1
„ „ varvicite =	7	+	4	=	1	+	3

And in point of fact some chemists consider them to be rather compounds of other oxides than as constituting peculiar oxides. There are two acids of manganese which are entirely artificial compounds, namely, the manganic acid and per-, or, more properly, the hyper-manganic acid.

Manganic Acid has not hitherto been obtained in a separate state; but manganate of potash is easily prepared by heating in a silver crucible one part of powdered binoxide of manganese and two parts of potash. When the mixture has been kept at a dull red heat for an hour, it may be poured out, and when cold put into a bottle and excluded from the air.

The manganate of potash thus obtained is of a green colour. During the operation of the heat one portion of the binoxide yields oxygen to the other, which is by this converted into manganic acid, and this, united with the potash, forms the salt in question, which has long been known by the name of *mineral chameleon,* on account of the change of colour which the solution undergoes: on the first addition of cold water a green solution is obtained; this soon becomes blue, purple, and red, and ultimately brown; hydrated binoxide of manganese separates, and the solution is rendered colourless. These changes are produced more quickly by employing hot instead of cold water; they are owing to the conversion of the manganate into red hypermanganate of potash, the varied tints being derived from a mixture of these two salts.

By keeping a strong solution of the green manganate of potash tranquilly, and allowing the clear liquor, when poured off, to evaporate in vacuo over sulphuric acid, the salt is obtained in crystals, which are anhydrous and permanent in their dry state, but must be kept from the contact of organic matter, which speedily decomposes the acid.

Manganic acid is composed of—

Three equivalents of oxygen . .	24
One equivalent of manganese . .	28
Equivalent	52

Hypermanganic Acid.—This may be prepared by several processes. Mix together four parts of finely powdered binoxide of manganese, three and a half of chlorate of potash, and five of hydrate dissolved in a small quantity of water. Evaporate the mixture to dryness, and heat it to dull redness in a platina crucible. The mass is to be added to a large quantity of boiling water; and when separated from the residual oxide of manganese, is to be quickly evaporated and allowed to crystallize; the crystals are to be washed with a very little boiling water, and are of a very deep colour.

Hypermanganic acid may be obtained in a separate state by decomposing the barytic salt with dilute sulphuric acid. It has a fine red colour, and is rapidly decomposed by organic matter, as paper or linen. It bleaches coloured matter; the aqueous solution begins to decompose when heated to 86°, and is totally decomposed at 212°; oxygen is given out, and binoxide of manganese is precipitated. Its salts are more permanent than the acid, and when heated they yield oxygen gas, deflagrate when thrown on burning charcoal, and detonate violently with phosphorus. A very minute portion of hypermanganate of potash imparts a very rich purple to a large quantity of water.

Hypermanganic acid is composed of—

Three and a half equivs. of oxygen . .	28
One equivalent of manganese . . .	28
Equivalent	56

Chlorine and Manganese form two compounds. The *protochloride* may be prepared by dissolving any pure oxide in hydrochloric acid, and evaporating the solution to dryness out of the contact of air. It is a pink-coloured lamellated mass, which attracts moisture readily from the air, and is very soluble in water, forming a solution which is nearly or quite colourless.

It is composed of—

One equivalent of chlorine . .	36
One equivalent of manganese . .	28
Equivalent	64

Perchloride of Manganese is prepared by the mutual decomposition of hydrochloric and hypermanganic acids. It is a greenish-coloured vapour, which, by cooling to 4°, condenses into a greenish-brown-coloured fluid. When it comes into contact with moisture it resolves again into hydrochloric and hypermanganic acids.

It is composed of—

Three and a half equivs. of chlorine . .	126
One equivalent of manganese . . .	28
Equivalent	154

Sulphur and Manganese may be combined by heating a mixture of sulphur and the binoxide. Sulphurous acid gas is evolved, and a greenish powder is left which gives out hydrosulphuric acid when dissolved in acids. It may also be prepared by the addition of a hydrosulphate to a sulphate of manganese. It is then precipitated in combination with water, which modifies the colour.

It is composed of—

One equivalent of sulphur . .	16
One equivalent of manganese . .	28
Equivalent	44

According to Berzelius manganese combines with several other metals, as gold, silver, copper, tin, and iron; with the last-mentioned combination takes place readily, and the iron is rendered harder, whiter, and more brittle by it; and it is stated that iron which contains manganese is best adapted for making steel. A small quantity of iron causes manganese to obey the magnet, and renders it less oxidable.

The salts of manganese are compounds of very little importance. As that which is most readily obtained in a pure state, and as offering a type of the soluble salts of this metal, we will mention the

Sulphate of Manganese.—This salt may be obtained by dissolving the protoxide or carbonate in dilute sulphuric acid; a solution is obtained, which is nearly colourless, or sometimes of a slight pink colour, owing to the presence of a little hypermanganic acid. By evaporation reddish prismatic crystals are obtained, which have a bitter taste, effloresce in a dry atmosphere, and are soluble in about two and a half times their weight of water.

This salt is decomposed by the alkalis ammonia, potash, and soda, which precipitate colourless hydrated protoxide; and by the carbonates, which throw down white protocarbonate of manganese, and all these precipitates readily acquire oxygen and a brown colour, and are converted into deutoxide. Ferrocyanide of potassium gives a white precipitate, and hydrosulphuret of ammonia an orange one. Manganese is not precipitated in the metallic state by any other metal.

Oxide of manganese tinges glass of an amethystine colour.

The oxides of manganese, and especially the binoxide, as containing most oxygen, are largely employed in the preparation of chlorine [CHLORINE] for the manufacture of bleaching-powder, or chloride of lime. It is employed in glass-making to correct the yellow colour which oxide of iron is apt to impart to the glass; it is used also in making the black enamel of pottery. Sulphate of manganese has also been used within a few years to give a brown colour in calico-printing.

MANGE, an eruptive disease to which many domestic animals, and particularly dogs, are subject. It usually occurs as the result of dirt and confinement, bad or deficient food, or some other circumstances producing a generally unhealthy condition. It has many analogies to the itch in man [ITCH]; and the fluid discharged from the eruption of the mange in horses and dogs has sometimes been known to produce the itch in the human skin. Both appear to depend in general on the presence of a minute species of Acarus which burrows beneath the skin, and thus excites the irritation and itching by which these diseases are peculiarly characterised.

MANGEL WURZEL. [BEET.]

MANGIFERA, a genus of trees of the natural family of *Terebinthaceæ*, tribe *Anacardiæ*, so called from the Malayan name (*manga*) of the fruit, and *fero*, I bear. Three or four species of this genus are enumerated, as *M. fœtida* of Loureiro, a native of Cochin China and the Moluccas; *M. laxiflora*, indigenous in Mauritius; and *M. sylvatica*, of Roxburgh, a native of the hilly districts bordering on Silhet, where it grows to a great size, and is called *lukshmee-am*. It bears a fruit which ripens in February and March, and is eaten by the natives, though not so palatable as even a bad mango. It is also dried and kept by them for medicinal purposes. *M. oppositifolia*, Roxb., a native of Rangoon, is proposed by Messrs. Wight and Arnott to be formed into a distinct genus.

The Mango tree however, *Mangifera Indica*, is alone of any consequence, and this as forming one of the most grateful fruits of the tropical parts of Asia; it extends also as far north as 30°, and has been successfully introduced into the West Indies. The trees grow to a great size, with an erect trunk, and dark-coloured cracked bark. The wood is of a whitish or a dull gray colour, porous, yet pretty durable if kept dry. The leaves are alternate, petioled, lanceolar, entire, often a little waved at the margins, firm, smooth, shining, and having, when bruised, a pleasant resinous smell. The flowers are yellow-coloured and small, but produced in great numbers, on large terminal erect panicles. Many perfect male flowers are often found interspersed with the hermaphrodite ones. Calyx five-parted. Petals five, lanceolate, twice the length of the calyx, furnished in the inside with a lobed glandular scale or crest. Stamen a single fertile one, with three or four filament-like bodies, which represent the abortive stamens. Ovary with its base immersed in the torus, obliquely oval, one-celled, with a single ovule attached to the side of the cell. Style one, from the upper edge of the ovary, curved downwards. Drupe oblong, or somewhat kidney-formed, also a little compressed like a kidney, fleshy, with a smooth rind, yellow or reddish when ripe, size various, but in general about as large as a goose's egg. Nut conformable to the drupe, but more compressed, woody, one-celled, two-valved, covered on the outside with many fibrous filaments, particularly in the worst sorts. The kernels are large. Embryo between erect and transverse. Cotyledons thick, fleshy. Radicle opposite to hilum.

The Mango is so well known as one of the most highly esteemed fruits of the East, that one is surprised to find it sometimes described as like nothing so much as a mixture of tow and turpentine. The latter is a secretion abounding in the family to which the Mango belongs, and may be secreted in larger quantities in neglected varieties, where also the filaments of the nut will likewise abound. But in well-cultivated varieties the fruit is sweet and rich-flavoured, juicy, and nearly as free of fibres as a melon. The kernels contain much nourishment, but are never used for food except in famines, when they are cooked in the steam of water, and used as an article of diet.

The tree is generally raised from seeds, which should be sown soon after they are gathered, but this is a very uncertain way of getting the finer varieties. Propagating by layers, and grafting by approach, are the only modes of certainly continuing fine sorts, as well as of improving them. These have the advantages also of bearing when small in size, that is, only a few feet in height, and therefore well suited to culture in the hothouses of Europe. Sweet states 'that the Mango ripens in this country when the plants are of a good size. Sandy loam, or a mixture of loam and peat, is most suitable to it, and the pits should be well drained, as the plants are apt to get sodden with too much water. Fresh seeds from the West Indies vegetate freely. The plant may also be increased from cuttings, which root best in sand under a hand-glass.' It would be advisable also to imitate its native climate as much as possible, that is, after winter, giving it dry heat with watering for some months, and then removing it into an orchideous house in the season of ripening its fruit.

MANGOSTEEN. [Garcinia.]

MANGOUSTES. [Ichneumon.]

MANGROVE. [Rhizophora.]

MANHEIM, or MANNHEIM, the capital of the circle of the Lower Rhine, in the grand-duchy of Baden, is situated in 49° 29′ N. lat. and 8° 28′ E. long., in a very fertile plain, at the junction of the Neckar with the Rhine. Over both rivers there are bridges of boats: that over the Rhine, which belongs to Baden and Bavaria in common, rests on 43 pontoons; that over the Neckar, which rests on 28 pontoons, is 200 paces in length. Manheim is a new city built with great regularity: it consists of broad, straight, parallel streets, of which 11 run in one direction, and are crossed by 11 others at right angles. The houses are handsome, of equal height, all of two stories, except those at the corners, which have three stories. The principal street, 1200 paces long and 60 feet wide, leads from the Neckar Gate to the palace of the grand-duke, which is a very magnificent building, and one of the finest of the kind in Germany; it is feet in length, occupying the whole side next the Rhine, and consists of two great quadrangles. The front next the Rhine is built of a red stone intermixed with a whiter kind, and the general effect resembles that of Hampton Court. In the bombardment by the French in 1795 part of the left wing was destroyed. The right wing contains a gallery of pictures, a cabinet of natural history, a collection of plaster casts of the most celebrated antiques, and a library of 60,000 volumes. There are besides several fine apartments, a large hall called the Rittersaal (Knights' Hall), and a handsome chapel. Among the other public buildings the most worthy of notice are the observatory, the merchants' hall, resting on 72 arches, and 160 paces in length, and adorned with a lofty tower; the new arsenal, which is 92 feet high, 200 paces long, and 118 paces deep; and the splendid church, formerly belonging to the Jesuits, the theatre, the Lutheran, Calvinist, and Catholic churches, three hospitals, &c. Of the ten squares, the handsomest are the Parade, in which there is a marble fountain (but without water), with five statues cast by Crepello, and the great market-place, in which there is a celebrated group called the 'Mercury Group,' by Vandebranden. Manheim likewise a gymnasium, a botanic garden, a mercantile school, an academy of painting and sculpture, and other establishments for education. The fortifications having been entirely demolished by the French, and the site subsequently converted into gardens, the inhabitants enjoy the benefit of beautiful public promenades, besides the fine park of the palace, which is nearly 200 acres in extent. The situation of Manheim in a fine country and near two large rivers would seem to give it great advantages as a place of trade, and several of its princes have turned their attention to this subject; but the same local circumstances have rendered it an important military station, and exposed it to sieges, bombardments, and the passage of hostile troops. There is however a considerable carrying and transit trade. There are manufactories of tobacco, shawls, linen, and playing cards, and bleaching-grounds and tanneries. In the environs there are numerous gardens, and hops are extensively cultivated.

Manheim was only a village till 1606, when the elector palatine, Frederick IV., laid the foundation of a fortress and a town; he assigned to each of the villagers an allotment of ground, and promised the free exercise of their religion to emigrants driven by religious persecution from France and the Netherlands, numbers of whom resorted thither. In the Thirty Years' War it was taken by Tilly, Duke Bernhard of Weimar, the French, and the Bavarians. In 1688 it was taken by the French general Melac, and desolated like the rest of the palatinate. In 1699 the elector Frederick William collected the scattered inhabitants, encouraged new settlers, and had the city fortified on Coehorn's system. His successor Charles Philip removed hither from Heidelberg in 1720, with his court and all the public officers, on account of the religious disputes with the Protestants. The first stone of the splendid palace was laid in 1720, and the building was completed in 1731. The next elector, Charles Theodore, founded many of the still existing literary and scientific institutions; but on the death of Maximilian Joseph, elector of Bavaria, in 1788, without issue, he succeeded him, and removed his court to Munich, which was a great loss to Manheim. It was taken, as already observed, by the French in 1795, by the archduke Charles in 1799, afterwards re-occupied by the French, and assigned to Baden by the treaty of Luneville in 1801. It has recovered in a great degree its former prosperity during the peace that has continued since the fall of Napoleon, and the population is now about 23,000 inhabitants.

(Sophie de la Roche, *Briefe über Manheim*; Helmina von Chezy, *Heidelberg*, *Manheim*, &c.; Hassel, *Geographie*; Stein, *Lexicon*; Cannabich, *Geographie*, &c.)

MANHEIM GOLD, a species of brass, which, according to Wiegleb, consists of three parts of copper and one part of zinc.

MA'NIA. [Insanity; Lunacy.]

MANICHÆANS, an heretical Christian sect, who derived their name from Mani, as he is called by the Persians and Arabians, or Manes or Manichæus, according to the Greek and Roman writers. The particulars of the life and death of this individual are variously reported by the Greek and Oriental writers; but it appears from all accounts that he was a native of Persia, or at least brought up in that country; that he was well acquainted with the doctrines of the Magi; that he attempted to amalgamate the Persian religion with Christianity; and that after meeting with considerable success, he was eventually put to death by Varanes I., king of Persia. It is difficult to determine the exact time at which the doctrines of Mani were first promulgated in the Roman empire; but they do not appear to have been known before the end of the third century or the beginning of the fourth.

The Manichæans believed, like the Magi, in two eternal principles, from which all things proceed, namely, light and darkness, which are respectively subject to the dominion of two beings, one the god of good, and the other the god of evil. They also believed that the first parents of the human race were created by the god of darkness with corrupt and mortal bodies, but that their souls formed part of that eternal light which was subject to the god of light. They maintained that it was the great object of the government of the god of light to deliver the captive souls of men from their corporeal prisons, and that with this view he created two sublime beings, Christ and the Holy Ghost, and sent Christ into the world, clothed with the shadowy form of a human body, and not with the real substance, to teach mortals how to deliver the rational soul from the corrupt body, and to overcome the power of malignant matter. Referring to the promise of Christ shortly before his crucifixion, which is recorded by John (xvi. 7-15), that he would send to his disciples the Comforter, 'who would lead them into all truth,' the Manichæans maintained that this promise was fulfilled in the person of Mani, who was sent by the god of light to declare to all men the doctrine of salvation, without concealing any of its truths under the veil of metaphor, or under any other covering. Mani also taught that those souls which obeyed the laws delivered by Christ, as explained by himself the Comforter, and struggled against the lusts and appetites of a corrupt nature, would, on their death, be delivered from their sinful bodies, and, after being purified by the sun and moon, would ascend to the regions of light; but that those souls which neglected to struggle against their corrupt natures would pass after death into the bodies of animals or other beings until they had expiated their guilt. Their belief in the evil of matter led them to deny the doctrine of the resurrection.

Mani entirely rejected the authority of the Old Testament, which he said was the word of the god of darkness, whom the Jews had worshipped in the place of the god of light. He asserted that the books of the New Testament had been greatly interpolated, and that they were not all written by the persons whose names they bear. The doctrines of the sect were contained in four works, said to have been written by Mani himself, which were entitled respectively 'Mysteries,' 'Chapters,' 'Gospel,' and 'Treasury;' but we know little or nothing of their contents.

Bower, in the second volume of his 'History of the Popes,' has attempted to prove that the Manichæans were addicted to immoral practices; but this opinion has been ably controverted by Beausobre and Lardner, who have shown that they were, on the contrary, exceedingly rigorous and austere in their mode of life.

The disciples of Mani were divided into two classes, one of which was called the *Elect*, and the other *Hearers*. The former were bound to abstain from animal food, wine, and all sensual enjoyments; the latter were considered as imperfect and feeble Christians, and were not obliged to submit to such a severe mode of life. The ecclesiastical constitution of the Manichæans consisted of 12 apostles and a president, who represented Christ; of 72 bishops, who also represented the 72 disciples of Christ; and of presbyters and deacons, as in the Catholic church.

The Manichæans never appear to have been very numerous, but they were spread over almost all parts of the Christian world. Numerous treatises were written against them, the most important of which were by Eusebius of Cæsarea, Eusebius of Emisa, Serapion of Thmuis, Athanasius of Alexandria, George and Apollinarius of Laodicea, and Titus of Bostra. Much valuable information concerning this sect may be found in the writings of Augustine, who was for nine years a zealous supporter of the Manichæan doctrines.

The Paulicians are generally considered to be a branch of the Manichæan sect, and are supposed to have appeared first in the seventh century in Armenia, and to have derived their name from Paul, a zealous preacher of the doctrines of Mani.

In the sixth century the Manichæan doctrines are said to have spread very widely in Persia. They continued to have supporters, under their new name of Paulicianism, till a very late period in ecclesiastical history. About the middle of the eighth century the emperor Constantine, surnamed Copronymus, transplanted from Armenia a great number of Paulicians to Thrace; where they continued to exist even after the capture of Constantinople by the Turks. In the eleventh and twelfth centuries the doctrines of the Paulicians were introduced into Italy and France, and met with considerable success.

(Neander's *Kirchengeschichte*; Mosheim's *Ecclesiastical History*; Lardner's *Credibility of the Gospel History*, Works, vol. iii., ed. of 1831; Gibbon's *Decline and Fall*, c. 54; Hyde, *De Religione Veterum Persarum*; D'Herbelot's *Bibliothèque Orientale*, art. 'Mani.')

MANICHORD, a keyed musical instrument, of the simplest kind, similar in all respects to the clavichord. [CLAVICHORD.]

MANI'LIUS, MARCUS or **CAIUS** (whose name is sometimes written Mallius or Manlius), a Latin poet, who wrote a work on astronomy, called 'Astronomicon,' in five books. We possess no particulars respecting his life, but the opinion of Bentley seems the most probable, that he was born in Asia, and lived in the time of Augustus Cæsar.

Some writers suppose Manilius to be the same person as the Manilius or Manlius of Antioch, the astrologer, mentioned by Pliny (*H. N.*, xxxv. 17), and others the same as Manlius the mathematician, also mentioned by Pliny (xxxvi. 15, s. 5); but the only reason for these opinions consists in the similarity of the names.

The 'Astronomicon' does not appear to be complete. The five books which are extant treat principally of the fixed stars; but the poet promises in many parts of his work to give an account of the planets. The 'Astronomicon' contains several passages which are not unworthy to be compared with some of the best writings of the Augustan age; but the subject gave the author little opportunity for the exercise of his poetical powers. It appears from many parts of the work that Manilius was a staunch adherent of the Stoic philosophy.

A MS. of the 'Astronomicon' was first discovered by Poggio in 1416. The best editions are by Bentley, Lond., 1739, and Stoeber, Argent., 1767. It has been translated into English verse by Creech, Lond., 1700.

MANILLA. [PHILIPPINE ISLANDS.]

MANIPULATION, in chemistry, embraces every part of the subject which is of a mechanical nature, such as the operations of weighing, measuring, the application of heat and electricity, the various modes of effecting solution, precipitation, distillation, and sublimation, and in fact every step in chemical research includes manipulation. It will be impossible therefore to treat of the whole of this subject under one head, and the most important parts of it will be found under their respective letters. [CALCINATION; DISTILLATION; FILTER, &c.] This subject is admirably treated in Faraday's 'Chemical Manipulation.'

MANIS. [PANGOLINS.]

MA'NLII, the name of one of the most illustrious patrician *gentes* of ancient Rome. Those most worthy of notice are:—

1. Marcus Manlius Capitolinus, who was consul B.C. 392 (Liv., v. 31), and was the means of preserving the capitol when it was nearly taken by the Gauls (Liv., v. 47), from which he obtained the surname of Capitolinus. He afterwards became a warm supporter of the popular party against his own order, and particularly distinguished himself by the liberality with which he assisted those who were in debt. He publicly sold one of his most valuable estates, and declared that as long as he had a single pound he would not allow any Roman to be carried into bondage for debt. In consequence of his opposition to the patrician order he was accused of aiming at the kingly power. The circumstances attending his trial and death are involved in much obscurity. It would appear that he was accused before the centuries and was acquitted; and that afterwards, seeing that the patrician party were determined on his destruction, he seized upon the capitol, and prepared to defend it by arms. In consequence of this Camillus, his personal enemy, was appointed dictator, and the curiæ (*i.e.* the patrician assembly) condemned him to death. According to Livy, who implies that Manlius did not take up arms, he was thrown down from the Tarpeian rock by the tribunes; but Niebuhr supposes, from a fragment of Dion (xxxi.) compared with the narrative of Zonaras (vii. 24), that he was treacherously pushed down from the rock by a slave, who had been hired for that purpose by the patrician party. (*Roman History*, vol. ii., p. 610, 611, Engl. transl.; Liv., vi. 11, 14, 20.) The house which had belonged to Manlius was razed; and the Manlian gens resolved that none of its patrician members should again bear the name of Marcus. Manlius was put to death B.C. 384.

2. Titus Manlius Capitolinus Torquatus, son of L. Manlius, surnamed Imperiosus, who was dictator B.C. 363. When his father Lucius was accused by the tribune Pomponius on account of his cruelty towards the soldiers under his command, and also for keeping his son Titus among his slaves in the country, Titus is said to have obtained admittance in the house of Pomponius shortly before the trial, and to have compelled him, under fear of death, to swear that he would drop the prosecution against his father. This instance of filial affection is said to have operated so strongly in his favour, that he was appointed in the same year (B.C. 362) one of the military tribunes. (Liv., vii. 4, 5; Cicero, *De Off.*, iii. 31.)

In the following year Manlius distinguished himself by slaying in single combat a Gaul of gigantic size on the banks of the Anio. In consequence of his taking a chain (*torques*) from the dead body of his enemy, he received his surname of Torquatus. (Liv., vii. 10.)

Manlius filled the office of dictator twice, and in both instances before he had been appointed consul: once, in order to conduct the war against the Cærites, B.C. 351; and the second time, in order to preside at the Comitia for the election of consuls, B.C. 346. (Liv., vii. 19-26.)

Manlius was consul at least three times. (Cic., *De Off.*, iii. 31.) In his third consulship he defeated the Latins, who had formed a powerful confederacy against the Romans. In the same campaign he put his own son to death for having engaged in single combat with one of the enemy, contrary to his orders. (Liv., viii. 5-12.)

3. Titus Manlius Torquatus was consul B.C. 235, and obtained a triumph on account of his conquests in Sardinia. (Vell., ii. 38; Eutrop., iii. 3.) In his second consulship, B.C. 224, he conquered the Gauls. (Polyb., ii.31.) He opposed the ransom of the prisoners, who had been taken at the battle of Cannæ. (Liv, xxii. 60.) In 215 he defeated the Carthaginians in Sardinia (Liv., xxiii. 34, 40, 41); and in 212 was an unsuccessful candidate for the office of Pontifex Maximus. (Liv., xxv. 5.) In 211 he was again elected consul, but declined the honour on account of the weakness of his eyes. (Liv., xxvi. 22.) In 208 he was appointed dictator in order to hold the Comitia. (Liv., xxvii. 33.) The temple of Janus was closed during the first consulship of Manlius. (Liv., i. 19; Vell., ii. 38.)

4. Cneius Manlius Vulso was consul B.C. 189, and appointed to the command of the war against the Gauls in Galatia, whom he entirely subdued. An account of this war is given by Livy (xxxviii. 12-17), and Polybius (xxii. 16-22). After remaining in Asia the following year as proconsul, he led his army home through Thrace, where he was attacked by the inhabitants in a narrow defile and plundered of part of his booty. He obtained a triumph, B.C. 186, though not without some difficulty. (Liv., xxxix. 6.)

MANNA, the concrete juice of the *Ornus Europæa*, a species of ash which is a native of the South of Europe, growing abundantly in Sicily, Calabria, Apulia, &c. The juice exudes spontaneously in warm dry weather, and concretes upon the bark of the tree; the finest manna is however procured by making longitudinal incisions of about three inches long. The manna flows at first in the form of a thick juice, which gradually concretes. The finest kind is called Calabrian or flake manna; it is in pieces of a pale yellowish white colour, is light, rather dry, and brittle, and it bears frequently the impression of the branch on which it concretes. It has a slight peculiar odour, and a sweetish taste, mixed with a slight degree of bitterness, and altogether leaves a disagreeable impression. Its texture is generally granular: but the finer pieces when broken are often hollow, and when examined by the microscope exhibit specular crystals. Manna is perfectly soluble both in water and in alcohol; the crystals deposited by cooling a hot spirituous solution constitute a peculiar variety of sugar, which has been called *mannite*; it differs however from common sugar in not being fermentable. According to Bucholz, 100 parts of flake manna contain about 60 of mannite, mixed with uncrystallizable sugar, purgative principle, gum, &c.

Mannite is composed of

	Prout.	Liebeg.
Hydrogen . .	6·8	7·62
Carbon . .	38·7	40·02
Oxygen . .	54·5	52·35
.	100·	99·99

Manna is employed as a gentle laxative, for children or persons of weak habits. It is however seldom exhibited alone, but as an adjunct to other more active medicines, as senna, rhubarb, &c. [ORNUS.]

MANNA, KINDS OF. Besides the genuine manna above described, other sweetish secretions are exuded by some other plants which are usually considered to be kinds of manna. These appear to be all produced in warm and dry parts of the world. The kind which is most abundant is by the Arabs called *toorunjbeen*, which is often translated 'Persian manna,' and is produced by a thorny plant, called by botanists *Alhagi Maurorum*. The genus Alhagi (a name compounded of *haj* and the article [illegible] of botanists contains two species, *A. maurorum* and *A. desertorum*, found in India, Egypt, Arabia, the north of Persia, and Syria. Both species are also called *ooshturkhar*, or camel's thorn. *A. maurorum* is alone remarkable for yielding a kind of manna, which by some authors has been supposed to be the Manna of the Wilderness; hence the plant itself was called *Manna hebraica* by Mr. Don. The climate of Persia and Bokhara seems alone suited for the secretion of this manna, which in the latter country is employed as a substitute for sugar, and is imported into India from Caubul and Khorassan. A second kind, which, though less abundant, is more esteemed than the former, is called *sher-khisht*, and is mentioned by Garcias under this name, and described as produced in the country of the Uzbecs. A Caubul merchant reported to Dr. Royle that it was produced by a tree called *gundeleh*, which was about twelve feet high, had a jointed stem, and grew in Candahar. A third kind of manna is called *guzunjbeen*, the produce of a species of Tamarisk, called *guz*, which is considered by Ehrenberg to be only a variety of *Tamariscus gallica*, growing on Mount Sinai, but which has been called *T. mannifera*: by some authors this is supposed to be the Manna of the Wilderness. It is said to be produced also in Laristan and in Irak Ajemi. A fourth kind of manna is produced on *Calotropis procera*, called *ashur*, and its sweet exudation or sugar *shukur-al-ashur*, under which name it is described by Avicenna; Zuccarum al-husar in the Latin translation, ch. 758. A fifth kind, called *bed-khisht*, is described in Persian works as being produced on a species of willow in Persian Khorassan. Besides these comparatively little known kinds of manna, a sweetish exudation is produced on the larch (Larix europea), which forms the Manna brigantiaca, or Briançon Manna of some Pharmacopœias.

MANNINGTREE. [ESSEX.]

MANNITE. [MANNA.]

MANO'METER (from two Greek words, μανός, thin or rare, and μέτρον, a measure) is the name given to instruments which measure the rarity of the atmosphere or other gas. As however the rarity of a gas is proportional to its elastic force, so long as its temperature and chemical composition remain unchanged, such instruments as measure the elastic force of gases are also, with this restriction, properly termed manometers, and accordingly it is to the latter instruments that the term is most frequently applied, both in this country and upon the Continent.

The 'statical barometer' of Robert Boyle was a manometer of the simplest kind, consisting of an exhausted glass globe suspended from one extremity of a delicate balance, and counterpoised by a metallic weight at the other extremity, the adjustment being made when the atmosphere was in its mean state of density. Any subsequent variation in the specific gravity of the air would, by a known law of hydrostatics, destroy the equilibrium, and the motion of the globe would indicate whether the variation had inclined towards an increase or diminution of density, as in the former case it would ascend, in the latter it would descend.

Captain Phipps, in his north-polar voyage, and Colonel Roy, in order to correct his barometric observations, employed manometers, which gave the elastic tension of the atmosphere. They consisted of glass tubes similar in form to thermometer tubes, and of various sizes. Those of Colonel Roy were from four to eight feet in length, with bores from one-fifteenth to one twenty-fifth of an inch in diameter. 'The bulb and part of the tube being filled with air of known tension, and the remainder of the tube being partially occupied by a small column of mercury sufficient to cut off the communication between the internal and external air; any variation in the elastic tension of the latter, arising from change of weight, would be accurately measured by the ascent or descent of the mercurial column. For whenever the tension of the atmosphere exceeded that of the contained air, the column would move towards the bulb, and the contrary. But if the change in the tension of the atmosphere were partly attributable to a change of temperature, then the motion of the column would merely measure the difference of the variations in the tension the internal and external air, because the tension of both would be equally affected by the change of temperature. The bulb was pear-shaped, so that the point being occasionally opened, dry or moist air could be readily admitted, and the bulb sealed again without any sensible alteration in its capacity.' (*Phil. Trans.*, vol. lxvii., p. 689.) The manometers of Varignon and Wolf were similar to the preceding.

A more convenient instrument, and one of more general use, consists of a siphon-barometer, the basin of which is enclosed air-tight in a globular or other conveniently shaped vessel, furnished with a number of cocks, by means of which and the pneumatic pump the contained gas may be removed and other gases successively substituted in its place. If equal parts by weight of different gases be thus successively introduced, they will not be affected by any change which may take place in the surrounding atmosphere, except in so far as such change may affect their temperature; so that, providing the temperature remain constant, the relative tensions of these gases will be accurately measured by the weight of the mercurial column suspended in the longer arm of the barometer, above the level of the mercury in the basin; care being had to allow for any variation in the capacity of the receiver, arising from alteration in the level of the mercury in the basin, and likewise for the small tension always indicated by the barometer immediately previous to the introduction of a fresh gas, arising from the impossibility of forming a perfect vacuum.

If an approximate vacuum be formed in the receiver enveloping the basin of the barometer, and a small quantity of any liquid be then introduced, it will be immediately converted into vapour, and the elastic tension of this vapour will be measured in precisely the same way as that of permanent gases. The receiver is sometimes of sufficient size to contain animals and plants, the effect of which in increasing or diminishing the tension of the enclosed gas is thus measured by the rise or fall of the mercury. If this manometer be transported from one place to another, where the temperature is the same, but the force of gravity different, this variation in the force of gravity will be manifested by a corresponding variation in the length of the mercurial column; that is, if the gravity increase, the tension of the enclosed gas will be counterbalanced by a shorter column of mercury, and the contrary; but as this method of measuring the variations in the force of gravity is not susceptible of that accuracy which is attained by the employment of the pendulum, it is rarely, if ever resorted to.

The exact determination of the elastic force of aqueous vapour at high temperatures being essential to the safe construction and management of steam-engines, the French government requested the Royal Academy of Sciences to institute a course of experiments, with a view to the attainment of so important an object. The care of making these experiments was confided by the Academy to MM. de Prony, Arago, Girard, and Dulong, who made their report in 1829. (*Annales de Chimie*, t. xliii., p. 74.) The manometer constructed for this purpose consisted of a straight glass tube of uniform bore, 1·7 mètres (67 inches) in length, and 5 millimètres (0·2 inches) in diameter and thickness, closed at the upper and open at the lower extremity. The capacity having been accurately determined, it was filled with perfectly dry air of known density, and enveloped in a cistern of water, which was kept at an uniform temperature. Another tube of equal bore and thickness, but 20 mètres (65 feet) in length, and open at both ends, was then erected, and the lower extremities of the two tubes were made to communicate with apertures in the opposite sides of a cylindrically-shaped reservoir, capable of holding about 1 cwt. of mercury. By means of a forcing-pump adjusted to the top of this reservoir, the pressure upon the surface of the contained mercury could be increased at pleasure; and this increased pressure, being transmitted to the lateral apertures already mentioned, would obviously cause the mercury to rise in both tubes, but to unequal heights; for in the longer tube it would rise until the weight of the mercurial column, together with that of the superincumbent atmosphere, were equal to the pressure; but in the shorter tube, only until this pressure was counterbalanced by the rapidly augmenting expansive force of the confined air, added to the weight of the small column of mercury forced into it. The expansive force of the compressed air would be measured by the difference of these two columns; and by this means, the shorter tube having been carefully graduated corresponding to pressures varying from one to twenty-nine atmospheres, the construction of the manometer was complete. The longer tube and the forcing-pump were then removed, as no longer necessary, and instead of the latter was substituted the actual pressure of steam at successively increased temperatures, the tension of which was indicated by the compression of the air in the manometer.

(For more minute information see the *Annales de Chimie*, as above cited; also Poisson, *Mécanique*, &c.)

(See Poisson, *Mécanique*, tom. ii., p. 512-15; Biot, *Physique Expérimentale*, i., p. 211; Gehler's *Dictionary of Physics*, iii. 136, v. 823; Fischer's *Dict.*, art. 'Manometer;' Sir H. Davy, in Nicholson's *Journal*, xx., p. 37; Gilbert's *Journal*, xv., p. 41; *Edinb. Phil. Jour.*, part I.)

MANON, a genus of Zoophyta, proposed by Schweigger, adopted by Goldfuss, and ranked by De Blainville among the Amorphozoa, with spongia, alcyonium, &c. It is an attached mass, full of lacunæ, composed of reticulated fibres, with its surface pierced by many distinct holes. Goldfuss gives nine species, of which five are from the chalk, two in Jura kalk, one in transition rocks.

MANOR (*Manerium*).

1. *Origin of Manors.*—At the time of the Norman conquest manerius or manerium (from *manere*, to dwell) denoted a large mansion or dwelling. The 'manerium' of the Exchequer Domesday is the 'mansio' of the Exeter Domesday, each being therefore the equivalent of the Anglo-Saxon or French term used by the officers who made the survey. [illegible] In France the corresponding word 'manoir' has never acquired any other signification than that of a mansion; and an estate possessing the peculiar incidents of an English manor never became so common in France as to require a specific name.

The modern English manor derives its origin from subinfeudation [Feudal System], as it existed before the modifications of the system of tenures introduced in 1225 by Magna Charta, and the still more important alterations made in 1290 by 'The King's Statute of buying and selling Lands,' commencing with the words 'Quia Emptores Terrarum,' and in 1324 by the statute 'De Prerogativâ Regis,' by which statutes, the process of subinfeudation, or of granting land, &c. in fee-simple, to be held by the grantee as a tenant or vassal to the grantor, was stopped.

Where a subinfeudation made by A to B extended to the whole of A's land, nothing remained in A but a seignory with the ordinary feudal incidents of tenure, together with such rents or other services as might have been reserved upon the creation of the subtenure. This interest in A was a seignory in gross, that is, a seignory held by itself, unattached to any land, an incorporeal seignory, termed by the French feudists 'un fief *en l'air*.' But in the case of subinfeudation of *part* of the land, the ordinary mode of proceeding was this:—A, a large proprietor, having a mansion and land at Dale, created a subtenure in a portion of his land by granting such portion to B and his heirs, to hold of A and his heirs, as of A's manerium (mansion) of Dale, which words created an implied condition that B should perform the service of attending, with the other tenants of A holding by virtue of similar subinfeudations, at A's halmote of Dale, that is, at A's court meeting in the hall of A's mansion at Dale (afterwards called A's court-baron of his manor of Dale), for the purpose of deciding judicially all disputes among A's free tenants holding of him by the same tenure as B, in respect of their lands so holden, and also all actions brought by persons claiming such lands.

Upon this subinfeudation being effected, A would continue to be the owner of the mansion of Dale and of that part of the land of Dale, of which he had made no subinfeudation, in demesne (in dominico suo),—as his own immediate property; and he would have the seignory of lands of which B and others had been subinfeudated, as a seignory appendant or legally annexed to the mansion of Dale, and to the demesnes of Dale, of which the mansion formed part.

This conjoint or complex estate, taking its denomination from the mansion (manerium), which was considered as its head, and which, in the language of the Year Book of P. 14, Edward II. (Maynard, 420), 'drew to itself all the appendancies,' by degrees acquired the name of manerium or manor.

A manor therefore *originally* consisted of lands in demesne, upon which the lord had a mansion, and to which lands and mansion, and more especially to the latter, there was appendant a seignory over freeholders qualified in respect of quantity of estate (*i.e.* by a tenancy for life at the least, if not a tenancy in fee-simple), and sufficient in point of number, to constitute a court-baron. These freeholders were called vavassors [Vavassor], and their lands 'tenemental lands,' *i.e.* lands granted out in tenure, to distinguish them from the lord's demesnes. These tenements tal lands, antiently known by the denomination of vavassories, though held of the manor and within the seigniory (or, as it was usually termed, within the fee) of the lord, were not considered as part of the manor; but the services issuing from such tenemental lands were part of the manor and essential to its existence.

Afterwards it was sufficient if the site of a mansion at which the services had been reserved, or, as it was called, the site of the manor, formed part of the demesnes; and, at last, this vestige of the origin of the name of the estate was dispensed with, and if the lord retained any portion of the land, so that there would be some demesnes to which the seigniory over the freehold tenants of the manor, and the services rendered by them, might continue to be appendant, the compound estate called a manor was not dissolved, whether it could be shown that a mansion had ever stood on the part of the demesnes or lands retained, or not, and even if the lord had aliened and severed from his demesnes the spot on which the mansion had once stood.

II. *Nature and incidents of Manors.*—A manor is commonly said to consist of demesnes and services. It is quaintly, but perhaps more correctly, stated by Fulbeck, that these 'are the material causes of a manor;' for though there can be no manor unless there be both demesnes and services, other things may also be members and parcel of a manor.

1. The demesnes are those lands within the manor, of which the lord is seised, *i.e.* of which he has the freehold, whether they are in his own occupation, or in that of his tenants at will, or his tenants for years. The tenants at will have either a common-law estate, holding at the joint will of the lessor and of the lessee, or a customary estate, holding at the will of the lord according to the custom of the manor. [COPYHOLD.] The tenancy for years of lands within a manor is, in modern times, usually a common-law estate, though in the assessionable manors, parcel of the duchy of Cornwall, customary estates for years still subsist (VIII.); and where a copyholder surrenders for years, the surrenderee becomes a customary tenant for years of the portion of the demesnes so surrendered.

2. The services of a manor are, the rents, and other services, due from freehold tenants holding of the manor. These services are annexed or appendant to the seigniory over the lands holden by such freehold tenants. The lands holden by the freeholders of the manor are holden *of* the manor, but are not *within*, or *parcel of*, the manor, though within the lord's fee, or manerial seigniory.

Copyholds, being part of the demesnes, are not held of the manor, but are within and parcel of the manor.

The demesne lands were formerly called the *inland*, and the tenemental lands, the *outland*, of the manor.

3. But though a perfect legal manor cannot exist without demesnes and services, other incorporeal hereditaments, which are not services, may be parcel of the manor, as advowsons, rights of common, rights of way, &c., and, under peculiar circumstances, even rents-seck and rents-charge.

In general, the power of holding courts of justice, whether for the decision of criminal matters or for the determination of civil rights, can be exercised only under authority derived from the crown, either by actual grant or by prescription; and in order to prevent usurpations of such a power, the crown may at any time issue process for the purpose of instituting an inquiry by what authority [QUO WARRANTO] a subject holds a court of justice. But it is a distinguishing feature of the feudal system, to make civil jurisdiction necessarily, and criminal jurisdiction ordinarily, coextensive with tenure. Upon this principle there is inseparably incident to every manor a court-baron (curia baronum), being a court in which the freeholders of the manor are the sole judges, but in which the lord, by himself, or more commonly by his steward, presides. The jurisdiction of the court-baron extends over all personal actions in which the debt or damages sought to be recovered are under 40*s.*; and real actions in respect of lands held of the manor could not have been brought in any other court, except upon an allegation that the lord of the manor had in the particular instance granted or abandoned his court to the king (quia dominus remisit curiam). To a quo warranto therefore for holding a court-baron, it is a sufficient answer—that the defendant has a manor. As this court was essential to the due administration of justice in questions respecting the right of property held of the manor arising amongst the lord's tenants, there could never have been a perfect manor without a sufficient number of freeholders to constitute the court-baron, which number must consist of three, or two at the least; three being necessary where the litigation was between two of the freeholders. The practice, which prevailed in France, &c., of *borrowing* suitors from the court of the lord paramount, to make up a sufficient number of freeholders to constitute a court, does not appear to have been adopted in England.

4. Some things are popularly supposed to be incident to a manor, which have no necessary connexion with it. Thus the ownership of wastes within the district over which the manor extends, is frequently called a *manerial* right, though the right and interest of the lord in wastes, over which no acts of ownership can be shown to have been exercised by him, rests entirely upon the presumption in favour of the lord, arising out of the circumstance of his being the present owner of the demesne lands, and the former owner of the tenemental lands which adjoin such wastes. The same presumption would arise in favour of any other owner of an extensive district. It is however true that lords of manors in their original grants, both to their freehold and to their copyhold tenants, usually reserved the waste lands, giving to the freeholders and copyholders merely rights of common over the wastes. Hence it arises that, in point of fact, manors, in proportion to their extent, frequently contain a much larger portion of wastes than other estates. From this cause, and from the circumstance of manors being generally large properties in the hands of the nobility and gentry, several statutes have given to lords of manors privileges in respect of game, and the appointment of gamekeepers, which other estates, though they may be of greater extent and value, do not enjoy. But except in particular cases in which a free-chase, free-warren [WARREN], or legal park [PARK] is, by royal grant or prescription, annexed to a manor, the lord of a manor has no privilege, in respect of game, beyond what is given him by these modern statutes.

Copyholds are a common incident to the demesnes of a manor, but there are many manors in which this species of tenure does not appear to have ever existed, and many more in which it has been long extinct; and though there are now no copyholds unconnected with a manor, the custom of demising by the lord's rolls appears to have formerly been common to every lord or freeholder who had demesnes which were held in villenage. So the right to have a court-leet is a royal franchise [LEET], under which the grantee holds a court of criminal jurisdiction in the king's name, over the resiants (residents) within a particular district. This privilege may be granted to persons who are not lords of manors; and where the grantee has a manor, the limits of the manor and of the leet are not always co-extensive.

Confusion often arises in the use of the terms 'within the manor,' 'within the fee and seigniory of the manor,' and 'within the ambit of the manor.' The first of these terms (and its equivalent 'parcel of the manor') applies to lands, &c., in the actual possession of the lord, or of his leaseholders or copyholders; the second, to lands which, having been formerly within the manor, were, before the statute of Quia Emptores, or De Prærogativâ Regis, granted by the lord to be held of the grantor in fee, as of his manor; the term 'within the ambit of the manor' is applicable to land, which though surrounded by the manor, is neither parcel of the manor nor held of the manor; land which never was connected with the manor in point of tenure, or which, having been formerly within the manor, has been in some way alienated from it in fee.

III. *Manors, how created.*—Since the statutes of Quia Emptores and De Prærogativâ Regis no manors have probably been created; and it has been commonly said that no new manor could afterwards be created. But as a proposition of law this appears to be stated too broadly. The former statute has been held not to apply to the immediate tenants of the king, who is not one of the 'magnates and other (*i.e.* inferior) lords.' The latter statute speaks only of lands held by knight's-service, and therefore, like the clause in the statute of wills imposing a restriction upon the devising of lands of that tenure, appears to be inapplicable since the abolition of military tenures. Besides, the statute of Quia Emptores Terrarum has been held to contain an implied exception in respect of alienations made with the licence of all lords, mediate or immediate; and in the statute De Prærogativâ Regis we find an express exception in favour of alienations made with the licence of the king. It seems to be questionable whether, even by the common law, the immediate tenant of the crown did not incur a forfeiture by making a subinfeudation without licence. (34 Edw. III., c. 15.) It has also been objected that a court-baron is necessary to a manor, and that a man cannot, by granting lands in tail, reserving suit at his court, create a court-baron. But this objection assumes that no greater subtenure can now be created than an estate tail, whereas, *with licence*, a subtenure in fee may be created, and the holding of a court-baron seems to be incidental at common law to the seignory over tenants in fee-simple.

Practically however an entirely new manor is now created; but where, upon the partition of a manor, part of the demesnes and part of the services, including suit of court of a sufficient number of freehold tenants to constitute a court-baron, are assigned to one parcener, jointtenant, or tenant in common, and other parts of the demesnes and services to another parcener, &c., each party has a manor, and may hold a court-baron. And it is said that if a manor extends into several townships, the lord may create separate manors by conveying the demesnes and services in township A to one, and those in township B to another.

It has been said that the king cannot at this day create a manor. From the nature of that species of estate it is obvious that the king never could create a manor. If the crown granted land to A, he might, with the licence of the crown, enfeoff B, C, and D of parcels of the lands, retaining the mansion, with or without other demesnes, in his own hands, and stipulating with B, C, and D, that they should render their services at such mansion. A would then have a manor; but it would not have been *created* by the crown, as the king neither did nor could create the subtenures of B, C, and D, out of which arose the services that, in conjunction with the demesnes, constituted the manor.

IV. *Manors, how destroyed.*—A manor is not destroyed by the loss of those incidents which, though members, and forming part, of the manor, are not, like demesnes and services, the 'material causes of a manor.' Nor will the legal existence of the manor be affected by the alienation of *part* of the demesnes, or by the alienation or extinction of *part* of the services, or by the extinction of all the copyholds. But upon the alienation of all the demesnes, or the alienation or extinction of all the services, the manor ceases, and is said to be destroyed; and though any part of the demesnes, however small, will keep alive the manor, if there be sufficient services, it can exist no longer than whilst there can be found enough *freehold* tenants to constitute a court-baron. Thus if the lord purchase the lands of all his freehold tenants, or of all except one, or if the freeholds escheat, or if the lord release or alien the services, the manor ceases to exist. So, if the lord alien the freehold of all lands holden of him by copy of court-roll, or enfranchise all the copyholders, in a manor where there are no demesnes except the copyholds. So, if he alien all the demesnes. So if, upon a partition of the manor, the demesnes are allotted to one and the services to another. But in none of these cases is the destruction of the manor absolute and irrevocable. If there cease to be any demesnes, so that the manor is turned into a *seignory in gross*, yet upon the event of any of the freeholds holden of the manor coming to the lord by escheat or purchase, the lands so escheating or purchased will become demesnes of the manor, as they were, before the subinfeudation of those lands, whereby they were originally severed from the manor, took place. Where a manor is destroyed by partition between co-parceners, if one die, and the other takes the share of the party dying as heir, the manor revives; but it would not be so in the case of a partition between joint-tenants or tenants in common; nor would the manor revive in the case of co-parceners if the severed portion of the manor were re-united, not by descent, but by purchase. Where all the freehold tenants have ceased to exist except one, there is no longer a complete legal manor, because there can be no court-baron; but if the remaining tenant convey his tenement in fee to different persons in severalty, as there will be now a sufficient number of freeholders holding of the manor, to constitute a court-baron, the manor will revive. But without such revival, the estate is by some lawyers considered to be still entitled to the designation of a manor, by reason of there being demesnes and a seignory appendant, though over one tenant only. (1 Anderson, 257.) Such an estate is however more frequently called 'a manor by reputation,' a vague term, applied indiscriminately to all estates which have been manors, and which indeed would be equally applicable to a property which had acquired the name of a manor without having ever been one.

If the lord of a manor make a gift in tail, or a lease for life, of all the demesnes, this is such a severance and alienation of the demesnes from the manor, that there will, during the continuance of the particular estate, be no demesnes within the manor. Whilst the estate tail, or the estate for life, continues, the services of the entailee, or tenant for life, and the reversion expectant upon the determination of such estate, will be parcel of the manor, but the *land* itself will be *holden of* the manor, and will not be *parcel* of the manor. Instead of demesnes and services, the lord will, for the time, have merely two classes of services, viz., those of the entailee, or tenant for life, and those of the antient freeholders in fee. During the continuance of this state of things the manor will be in suspense, and the lord will have, not a manor, but a double seignory in gross, or rather two seignories in gross, one in respect of the entailee, or lessee for life, the other in respect of the antient freehold tenants of the manor in fee.

V. *Manors, Customary.*—So much importance formerly attached to the possession of a principal mansion at which the services of tenants might be rendered, that a person holding lands in customary villenage might grant portions of his villenage to be holden of the grantor for as great an estate as the grantor had, as of his mansion or messuage. The estate of the grantor, which, after this operation, would consist of the mansion and the other ungranted portions of the villenage, with the services of the grantees appendant thereto, was called a customary manor.

The estate of a person to whom the lord of a manor has granted the freehold and seignory of all the copyholds within the manor or within a certain district, has been sometimes loosely called 'a customary manor.' But such an estate cannot, in any sense, be said to consist of demesnes and services.

VI. *Manors in Antient Demesne* are those manors which, though now mostly in the hands of subjects, formed part of the royal domain at the time of the Conquest, and are designated in Domesday as 'terra regis.' The peculiarity of these manors is, that there exists in them a particular class of tenants possessing certain customary privileges supposed, by Lord Coke and others, to be derived from the indulgence of the crown in matters 'pertaining to the king's husbandry.' They were formerly called 'tenants in socage in antient tenure,' but are now commonly known as 'tenants in antient demesne,' a term not in itself very accurate, since all tenants within these antient demesne manors, whether copyholders or freeholders, and even the lord himself, are strictly speaking tenants *in* antient demesne. In these customary tenures the freehold is not in the lord, but in the tenant, who is therefore called a customary *freeholder*; and it does not appear to be necessary to the continuance of the manor that there should be any other freehold tenants, though lands may be held of a manor in antient demesne by the ordinary freehold tenure, which lands are called lands in frank-fee by way of distinguishing them from the customary freeholds held by the 'tenants in socage in antient tenure,' now called 'tenants in antient demesne.'

Lord Coke enumerates six privileges as annexed to this peculiar tenure. (4 *Inst.*, 269; Bac., *Abr.*, 'Antient Demesne;' Com., *Dig.*, 'Antient Demesne.')

VII. *Manors in Border Counties.*—The exposed state of the northern borders of England, liable to hostile incursions in time of war, and scarcely less in times of nominal peace, created a peculiar species of tenure in the manors in the four northern counties. Persons holding by this tenure are called customary freeholders; though here the *freehold* is in the lord, and the timber and mines belong to him, and not (as in the tenure in antient demesne) to the tenants; but they are so called because they are allowed the privilege of passing their estates, as freeholders do, by feoffment and livery, a privilege perhaps derived from the irregularity with which the customary courts of the manor were held, and from the necessity of allowing persons whose tenure of land and of life was so uncertain to make immediate dispositions of their property.

VIII. *Manors, Assessionable*, a term peculiar to that part of the domain of the duke of Cornwall [Wales, Prince of] which is situate within the county of Cornwall, consisting of seventeen manors, namely, Launceston, Tremeton, Tyntagell, Restormel, Stoke-Climsland, Tybeste, Tewington, Helston-in-Kerrier, Moresk, Tywarnhaile, Penkneth, Penlyn, Rellaton, Helston-in-Trigshire, Liskeard, Calstock, and Talskydy.

The earls and dukes of Cornwall, and, when no earl or duke, the crown, have sent from time to time (commonly every seven years) certain persons commissioned to visit these manors in succession, and to *assess* the lord's demesnes, *i.e.* to let them at such rents and upon such terms as might appear to them to be advantageous to the duchy. The courts held by the commissioners for the purpose of exercising the authority thus delegated to them were called *assessions*, or courts of *assession*. The course usually was to let the land until the next assession. From the conventions (covenants or engagements) entered into by the persons to whom those demesnes were so arrented, the interest demised was called a tenure *in conventione*, and the tenants were styled conventionaries. These demises were made both to freemen and villeins; the former being called free conventionaries, the latter villein or native conventionaries. The latter class appear to have become extinct in the 16th century.

By degrees the conventionary tenants acquired an inheritable interest in the certainty of the renewal of their holdings in favour of themselves and their descendants at each successive assession. The conventionary tenant thus acquired, like a copyholder of inheritance, an interest freehold in point of duration, without a freehold tenure.

In conventionary tenements the minerals belong to the lord, and not to the customary tenant; as it was held upon a trial at bar in 1829, which lasted seven days (*Rowe* v. *Brenton*, 3 Mann. and Ryl., 133-364.)

MANS, LE, a town in France, capital of the department of Sarthe, situated on the river Sarthe, in 48° 1′ N. lat. and 0° 11′ E. long.; 111 miles from Paris in a direct line west-south-west, or 122 miles by the road through Versailles and Chartres.

This town existed in the time of the Romans, and was called Suindinum. It was the capital of that division of the Aulerci called Cenomani or Cenomanni, from whom it took in the fourth century the name of Cenomanni, a fragment of which remains in its modern designation. In the age of Charlemagne it was considered one of the principal cities of France. It was the chief town of the province of Maine. It is said to have been besieged twenty-four times between the reign of Clovis and that of Henri IV. inclusive. It was occupied by the royalists of Vendée in A.D. 1793, to the number of 60,000. They were driven out by General Marceau with the loss of many men and much plunder. It was surprised by a party of Chouans in A.D. 1799.

The town stands on the left bank of the Sarthe, a little above its junction with the Huine, and consists of two parts or quarters. The old quarter, on the bank of the river, consists of four or five streets nearly parallel to each other, narrow, dark, and dirty, connected by lanes or passages, some of which have steps, while others are so steep as to be impracticable for horses and carriages. The new quarter, on a hill not immediately adjacent to the river, occupies a larger space than the old, and has an equal population: it is well built and agreeable, though irregularly laid out. The Place des Halles is the largest and finest in the town. The Place des Jacobins, planted with trees, was formed, together with an adjacent public walk, in 1790, on the suppression of the religious houses. The walk covers the site of a Roman amphitheatre, which was discovered by the workmen in laying it out. There is another public walk on the bank of the Sarthe. The principal building is the cathedral, built on the foundations of an antient temple. The nave is the most antient part, and is ascribed to the ninth century by some, but to the eleventh by others: the choir and transepts are of later date, perhaps of the fifteenth century. The choir is admired for the loftiness of its roof, the boldness of its architecture, and the beauty of its stained glass. There is a tower at the extremity of one of the transepts, rising above 200 feet from the ground. The cathedral is surrounded by thirteen small chapels. There are several other churches: that attached to the seminary for the priesthood and the Church of the Visitation are modern buildings. That of La Couture, formerly conventual, is antient. The abbey of St. Vincent is now occupied as the seminary for priests; it has a fine front: the building formerly used for the seminary is now a barrack. The high school is held in an old monastic building, and the abbey of La Couture has been converted into the prefect's office: rooms in it are occupied by a public library of 40,000 or 50,000 volumes, and 700 MSS., a museum of natural history, and a collection of paintings. The town-hall is built on the site of the former palace of the counts of Le Mans, which itself occupied the site of some Roman building, of which there are yet some remains. The court-house is well laid out, and there is a theatre. The houses in the town are chiefly built of stone, and covered with slate.

The population in 1831 was 19,672 town, 19,792 whole commune; in 1836 it was 23,164 for the commune. There are considerable manufactures of woollens, cottons and linens, hosiery, lace, wax candles, and soft soap. There are bleaching establishments for linen and wax, tan-yards, currying-shops, paper-mills, and breweries. Considerable trade is carried on in the manufactured articles and in the agricultural produce of the neighbourhood, including chestnuts, walnuts, dried fruits, fat fowls, which are sent to Paris, and trefoil seed, sent to Russia, Sweden, and England. The weekly cattle-market is well attended; and there are two yearly fairs of eight days each. The town is the emporium of the surrounding country. There are good inns, coffee-houses, reading-rooms, and public baths.

There are several fiscal or judicial government offices, a seminary, and a high school, a society of agriculture, sciences, and arts, a royal society of arts, a free school for drawing, an hospital, and some other charities. It is the seat of a bishopric, the diocese of which includes this department and that of Mayenne: the bishop is a suffragan of the archbishop of Tours.

The arrondissement of Le Mans comprehends ten cantons or districts, each under a justice of the peace, and 1[illegible] communes. The area of it is 734 square miles. The population in 1831 was 157,851; in 1836, 164,667.

MANSARD, the name of two French architects of great celebrity in the seventeenth century. François Mansard, the elder, whose father, Absalon, is said to have been architect to the king, or at least a builder in the royal service, was born at Paris in 1598. At the age of twenty-two he began to distinguish himself by his restoration of the Hôtel Toulouse; and a short time afterwards he was commissioned to execute the portal of the church of the Feuillans, in the Rue St. Honoré. The reputation he acquired by these works soon procured him abundant employment, and obtained for him ample opportunities for displaying his talents. Among the numerous châteaux erected after his designs, may be mentioned Berni near Paris, Baleray, Blerancourt, Choisy, and that of Maisons, which last was built for the president De Longueil, and is generally considered his *chef-d'œuvre* among his edifices of that class.

Among his churches the most noted is that of the Val de Grace at Paris, the dome of which, said to have been designed after that of the chapel of the Château de Fresnes, built by himself, has been generally extolled as a fine piece of architecture, although now it would be considered a grotesque composition remarkable for nothing so much as the impure and meagre taste it displays, many of the forms being absolutely barbarous. The façade of the church of the Minimes in the Place Royale is also by him; and has been admired as exhibiting the solution of a knotty problem, the metopes being perfect squares throughout! Such was the puerile and pedantic trifling that formerly engaged the attention of architects and connoisseurs, and for the sake of which they overlooked matters of infinitely greater importance in architectural taste and design.

François died in 1666. This architect is said to have been the inventor of the curb roof, called, after him, a *Mansard*, which consists of two planes on each side, a steeper one below and a flatter one above. It has however little beauty of form to recommend it, having very much the look of being broken or doubled.

MANSARD, JULES HARDOUIN, was the nephew of the preceding, being the son of a painter who had married the sister of François. Jules, who assumed his maternal family name on becoming heir to his uncle, was born in 1648. He was brought up by François to his own profession, in which he afterwards so greatly distinguished himself, as to become much the more celebrated of the two. Most assuredly he had ample field allowed him for the display of his talents, since, had he been employed on no other work, he was called to execute one which for lavish prodigality has hardly its parallel in any age or country. It be-seems therefore quite as much a satire as a eulogium on his 'genius' to say that on that occasion, and with unlimited resources he produced nothing better than Versailles—a huge pile of building, which our own eminent architect Sir C. Wren described as composed of 'heaps of littleness.' Even his biographer Quatremère de Quincy, though anxious to impress us with a high idea of his talents, is obliged to admit that his designs display 'une certaine médiocrité de goût,' to which he might have added, a mediocrity of ideas also. It would not be difficult to select from his works numerous instances of exceedingly bad taste, of puerile caprices, and downright solecisms. Undoubtedly the magnitude and the costliness of these decorations give them an imposing air, but the effect thus produced is not to be ascribed to the architect himself—at least he must consent to share the fame so derived to him, with others. After Versailles, the work which has chiefly contributed to his reputation is the dome of the Invalides at Paris, which, although as splendid as a coat of gilding can make it, is externally greatly inferior to that of our St. Paul's in harmony and majesty of design and proportions. The plan of the interior of the edifice presents far more that deserves commendation, the whole being most skilfully arranged for perspective effect. Both the Place Louis XIV. and that called Des Victoires at Paris were built after his designs, but have little at all remarkable, except it be that the one is an octagon, and the other an oval in plan.

With abundance of most lucrative employment, and enjoying the personal favour of a monarch who was uniformly lavishly profuse, and by whom many profitable appointments were bestowed upon him, it is no wonder that Jules Hardouin was enabled to amass a vast fortune. He died suddenly at Marly in 1708, in his sixty-third year, and was buried in the church of St. Paul, at Paris, where a monument was erected to him, executed by the sculptor Coysevox.

MANSFIELD, a market-town and parish in the northern division of Broxtow wapentake, in the county of Nottingham. The population of the parish in 1831 was 9426. The town is seated in a valley near the little river Mann, or Maun, from which it probably takes its name, and is surrounded by the ancient forest of Sherwood, the scene of Robin Hood's chief exploits. [Hood, Robin.] Its direct distance from Nottingham is 12 miles north by west, and from London 138 miles north-north-west. The parish church, dedicated to St. Peter, is commodious; the living is a vicarage in the diocese of York and patronage of the dean of Lincoln, producing a net revenue of 135*l.* The principal streets are paved, and lighted with gas. A railway, seven miles in length, has been constructed at an expense of 20,000*l.*, connecting Mansfield with the Cromford canal, which is said to have proved very advantageous to the trading interests of the place. There are some extensive cotton-mills, besides manufactories of hosiery and lace. The market-day is Thursday, and the cattle-fairs are held on the 5th of April, 10th of July, and the second Thursday in October. The free grammar-school was founded by royal charter in the third year of the reign of Queen Elizabeth, who also established two scholarships of 10*l.* each at Jesus College, Cambridge, for scholars from this school. The inefficient state into which this school had been allowed to fall was a subject of general complaint among the inhabitants as recently as the year 1832. According to the charter of foundation the salaries of the master and usher are to be paid out of the produce of the church lands, which it is directed shall be distributed in the proportion of two-thirds to the vicar, two ninths to the master, and the remaining one-ninth to the usher; and it appears that the master's share amounted to 133*l.* in 1832, when the number of scholars, including eight boarders, was twenty-seven.

In 1725 Faith Clarkson bequeathed 2000*l.*, part of which she directed should be appropriated to the erection of a charity-school in Mansfield, and the remainder invested in lands for charitable purposes. By a decree of the court of chancery in 1753 it was ordered that a portion of the rental of these lands should be applied to the maintenance of a master and mistress to instruct twenty poor boys and the like number of girls in reading, writing, and arithmetic; the remainder was allotted to the clothing of all the children, and apprenticing a certain number of the boys. There is ample information as to the grammar-school and the other charitable institutions of Mansfield, in the Twenty-fifth Report of the Charity Commissioners, and in the second volume of Throsby's edition of Thoroton's *History of Nottinghamshire*, 4to. 1797.

In the neighbourhood of Mansfield-Woodhouse, a village about a mile and a half from the town of Mansfield, two Roman villas were discovered by Mr. Rooke in 1786; and in the vicinity of Mansfield numerous coins of the emperors Vespasian, Constantine, Antoninus Pius, and Marcus Aurelius have been found at different times.

(Harrod's *Hist. and Antiquities of Mansfield*, 4to. 1801; and *Parliamentary Papers*.)

MANSFIELD, WILLIAM MURRAY, EARL OF, lord-chief-justice of the king's bench, was born at Perth on the 2nd of March, 1704, O.S. He was the fourth son of Andrew Viscount Stormont. At the age of three he was removed to London, and in 1719 he was admitted a king's scholar at Westminster school. On the 18th of June, 1723, he was entered at Christ Church, Oxford, where, as before at Westminster, he distinguished himself by his classical attainments. After taking his degree of M.A. he left the university in 1730, and after travelling some time abroad he was called to the bar in Michaelmas term, 1731. In early life he appears to have associated a good deal with the 'men of wit about town.' Dr. Johnson said of him that 'when he first came to town he drank champagne with the wits.'

It has been said of him, as of other eminent lawyers, that he had been heard to say that he never knew the difference between a total want of employment and an income of 3000*l.* a year. But in 1732, the year after his being called to the bar, it appears that he was engaged in an important appeal case; and in the two following years he was frequently retained in similar cases before the House of Lords. (Holliday's *Life*, p. 23.) The first cause in the common-law courts in which Mr. Murray distinguished himself was an action for criminal conversation brought by Theophilus Cibber against Mr. Sloper. A sudden attack of illness having prevented his leader from appearing in court, the duty of conducting the defence devolved upon him. The result brought him an influx of business which at once raised his income from a few hundreds to thousands. In 1742 he was appointed solicitor-general, and obtained a seat in the House of Commons, where his eloquence and legal knowledge soon rendered him very powerful.

In the House, Murray and Pitt (Lord Chatham) were opposed to each other as the best speakers of their respective parties. Pitt's attacks on Murray seem to have occasionally exceeded the limits prescribed by modern parliamentary regulations. 'Brilliant and argumentative as was the oratory of Murray,' says Mr. H. Roscoe (*Lives of Eminent British Lawyers*, p. 180, in *Cabinet Cyclopædia*), 'he did not always possess the nerve necessary to ward off or to return assaults so terrible as these, and for the most part he bore in agitated silence the attacks to which he did not venture to make any reply.'

In 1754 Mr. Murray was made attorney-general, and in 1756 he received the appointment of chief-justice of the king's bench, and was immediately created a peer, by the title of Baron Mansfield, of Mansfield in the county of Nottingham. On his elevation to the seat of chief-justice, Lord Mansfield, contrary to the general usage, became a member of the cabinet.

Few lawyers have been more tempted than Lord Mansfield to quit their profession for politics. On several occasions (such was his power as a speaker and such was the opinion entertained of his abilities by his party) high political office, with the prospect of higher, or indeed the highest, was pressed upon his acceptance. But whether it was prudence or a certain timidity of character which appeared in him on many occasions throughout his life, that guided his conduct, it is certain that he was firm in refusing all offers of the kind and in adhering to his profession. Thus when the duchy of Lancaster and a pension of 2000*l.*, with the reversion of a valuable post for his nephew, Lord Stormont, were offered to him, and subsequently the amount of the proposed pension was raised to 6000*l.*, he was firm in his refusal. 'He knew,' says Walpole, 'that it was safer to expound laws than to be exposed to them; and he said peremptorily at last, that if he was not to be chief-justice, neither would he any longer be attorney-general.' Shortly after Lord Mansfield's promotion to the bench, on the dismissal of Mr. Pitt, and the resignation of Legge, the chancellor of the exchequer, the seals of the latter office were *pro tempore* placed in the hands of Lord

Mansfield, and he was entrusted by the king with full power to negotiate on the subject of a new administration with Mr. Pitt and the Duke of Newcastle. The same reasons which made him refuse political office seem to have induced him to decline the custody of the great seal when it was, upon more than one occasion, offered to him. He preferred the purely judicial office of chief-justice of the king's bench, where he was safe from political storms and the vicissitudes which they produce. Yet in that office, though safe from political, he was not safe from popular storms. His political leanings were not towards the popular side; and even his conduct as a judge, though now, when at a distance from him and his time we can survey it with calmness, it may appear deserving of a very small portion of the reprehension heaped on it by such writers as Junius, was at the time not free from the appearance of some bias against popular rights. The following passage from a speech of his in the House of Lords gives his opinion on the subject of seeking popularity, for which he always entertained a great contempt. 'It has been said by a noble lord on my left hand, that I likewise am running the race of popularity. If the noble lord means by popularity that applause bestowed by after-times on good and virtuous actions, I have long been struggling in that race, to what purpose all-trying time can alone determine; but if the noble lord means that mushroom popularity that is raised without merit and lost without a crime, he is much mistaken in his opinion. I defy the noble lord to point out a single action in my life, where the popularity of the times ever had the smallest influence on my determinations. I thank God, I have a more permanent and steady rule for my conduct—the dictates of my own heart. Those that have foregone that pleasing adviser, and given up their minds to be the slaves of every popular impulse, I sincerely pity; I pity them still more, if their vanity leads them to mistake the shouts of a mob for the trumpet of fame. Experience might inform them, that many, who have been saluted with the huzzas of a crowd one day, have received their execrations the next; and many who, by the popularity of their times, have been held up as spotless patriots, have nevertheless appeared upon the historian's page, when truth has triumphed over delusion, the assassins of liberty. Why, then, the noble lord can think that I am ambitious of present popularity, that relic of folly and shadow of renown, I am at a loss to determine.' (*Parl. Hist.*, vol. xvi., p. 977.)

In the cases of the trials of the publishers of Junius's letter to the king, Lord Mansfield incurred much popular odium by laying down the doctrine that the fact, not the law, was what the jury had to consider. In the trial of Woodfall, Lord Mansfield, in his summing up, directed the jury, 'that the printing and sense of the paper were alone what the jury had to consider of.' (*State Trials*, vol. xx., p. 900.)

In the case of Wilkes, which occurred in the same year, Lord Mansfield remained firm to his former opinion, and in allusion to the odium which he had incurred in consequence, thus expressed himself: 'I honour the king and respect the people; but many things, acquired by the favour of either, are, in my account, not worth ambition. I wish popularity, but it is that popularity which follows, not that which is run after. It is that popularity which, sooner or later, never fails to do justice to the pursuit of noble ends by noble means. I will not do that which my conscience tells me is wrong, upon this occasion, to gain the huzzas of thousands, or the daily praise of all the papers which come from the press: I will not avoid doing what I think is right, though it should draw on me the whole artillery of libels, all that falsehood and malice can invent, or the credulity of a deluded populace can swallow. I can say with a great magistrate, upon an occasion and under circumstances not unlike, "Ego hoc animo semper fui, ut invidiam virtute partam, gloriam, haud infamiam, putarem."'

In the famous riots of 1780, Lord Mansfield's house in Bloomsbury Square was attacked and set fire to by the populace. The walls were all that were left of it. His library of books and MSS., his private papers, pictures, furniture, and other valuables were all consumed. Though the treasury, in pursuance of a vote of the House of Commons, applied for the particulars and amount of his loss, with a view to compensation, his lordship declined returning any account of his loss, lest, he said in his letter to the Treasury, 'it might seem a claim or expectation of being indemnified.'

After having presided for upwards of 32 years in the court of king's bench, he retired from his office in 1788. He died on the 20th of March, 1793, in the 89th year of his age. He left no issue. The earldom of Mansfield, which was granted to him in 1776, descended to his nephew, Viscount Stormont.

Lord Mansfield's judicial character stands high. His acute and powerful intellect enabled him to take a clear and comprehensive view of every case. The depth of his legal learning has been questioned; probably not without reason. And this want of depth, assuming it to have existed, may account for his sometimes making law instead of expounding it—a thing sometimes unavoidable in a judge; and though extremely difficult to do well, easier to do ill or indifferently than to unravel and set forth in luminous order a large and confused mass of law already existing on a given subject: which suggests the reflection, that though that judge who is the profoundest lawyer will be the most competent to make law, at least to know when it is necessary to make it, yet those judges who are the least profound lawyers, and consequently the least able to say when law needs to be made, will be the most likely to evade the difficulty of elucidating the old law by making new. This is matter of every-day experience to lawyers. Lord Mansfield's judicial legislation has been most successful in some branches of commercial law. In the law of real property he was less successful. For example, his decision in the case of *Perrin* v. *Blake*, which involved an alteration in the old established rules of law, particularly as regarded what is called the rule in Shelley's case, was reversed in the Exchequer Chamber. (Fearne's *Contingent Remainders*, p. 158; and Dougl., *Rep.*, 329 or 343 of 3rd edition, in note.)

In reviewing the character of Lord Mansfield, his principles of toleration in matters of religion, which he maintained both in parliament and on the bench, ought not to be forgotten.

(*Life of Lord Mansfiell*, by Henry Roscoe, Esq., Barrister at Law, in Dr. Lardner's *Cabinet Cyclopædia.*)

MANSLAUGHTER. [MURDER.]

MANSOURA. [EGYPT.]

MANTEGNA, ANDREA, was born at Padua, in 1431. His parents were persons in humble life. It does not appear under what circumstances or at what age he became a pupil of Francesco Squaricone, who was so struck with his talents that he adopted him as his son. On Andrea marrying a daughter of Jacopo Bellini, Squaricone's competitor, the latter was offended, and censured his pupil as much as he had before praised him; but these censures, being in many instances well founded, only tended to his improvement, which was further promoted by the friendly advice of the brothers Gentile and Giovanni Bellini.

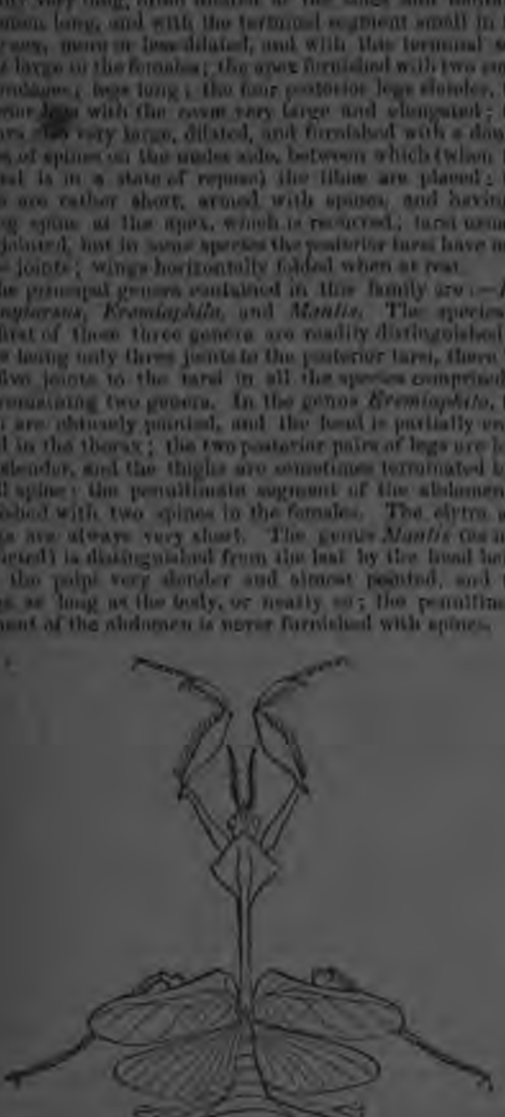
His chief residence and his school were at Mantua, where he settled under the patronage of the marquis Lodovico Gonzaga, but worked occasionally at other places, especially Rome. There are several of his oil paintings in Mantua. His master-piece, the picture Della Vittoria, which was in the Oratorio de' Padri di S. Filippo, was taken by the French and placed in the Louvre. We are not certain where it now is. M. Fuseli, who saw it in the Louvre, speaks of it in the highest terms. Few of this painter's works now remain, and most of them have been much injured. One of his greatest and most celebrated works, 'The Triumph of Julius Cæsar,' was part of the rich gallery of paintings that belonged to the Gonzaga family, which was purchased by King Charles I. for 80,000*l.* This, the greatest and most esteemed work of Mantegna, consisting of nine pictures, each 9 feet high and 9 feet wide, is now at Hampton Court. Unhappily it was coarsely painted over by Laguerre, in the time of William III. 'The Triumph of Scipio,' painted in black and white, and in admirable preservation, is in the possession of Sir George Vivyan. The earl of Pembroke has a picture by Mantegna, representing Judith with the head of Holofernes; and in the British Museum there is an admirable drawing in bistre touched with white, representing the dominion of the vices over the virtues, a counterpart to Mantegna's picture in the gallery of the Louvre (No. 1107), representing the vices expelled by the virtues. It is not probable that he painted many cabinet pictures, his time being so much occupied by large works and engraving: though not the inventor of this art, he was the first engraver of his time; the series of plates executed by his own hand exceeds fifty. Mantegna died in 1505, at the age of 74. (Pilkington and Fuseli, *Dictionary of Painters*; Waagen's *Arts and Artists in England.*)

MANTELLIA, a generic name proposed by Parkinson (*Org. Remains*) for certain alcyoniform fossils of the chalk. M. Brongniart has established the use of this word for certain cycadiform plants, to which Dr. Buckland has applied the title of Cycadeoideæ. The specimens are chiefly found in the oolite of the Isle of Portland, but one (M. cylindrica) occurs in the lias of Lunéville, according to M. Voltz. The stem of these plants is cylindrical or spheroidal, and covered with transverse impressions of leaf bases. The internal structure resembles Cycas. (Buckland, in *Geol. Trans.*, 1828.)

MANTES. [Seine et Oise.]

MA'NTIDÆ, a family of Orthopterous insects, the species of which may be distinguished by the following characters:—Head exposed (not hidden by the thorax), furnished with three ocelli, or simple eyes, beside the ordinary pair of compound eyes; palpi short, slender, and cylindrical; antennæ generally setaceous, but sometimes pectinated; short in the females and long in the males; body elongated; the thorax usually very long, often dilated at the sides and dentate; abdomen long, and with the terminal segment small in the males, more or less dilated, and with the terminal segment large in the females; the apex furnished with two small appendages; legs long; the four posterior legs slender, the anterior legs with the coxæ very large and elongated; the femora also very large, dilated, and furnished with a double series of spines on the under side, between which (when the animal is in a state of repose) the tibiæ are placed; the tibiæ are rather short, armed with spines, and having a strong spine at the apex, which is recurved; tarsi usually five-jointed, but in some species the posterior tarsi have only three joints; wings horizontally folded when at rest.

The principal genera contained in this family are:—*Heteronytarsus*, *Eremiaphila*, and *Mantis*. The species of the first of these three genera are readily distinguished by there being only three joints to the posterior tarsi, there being five joints to the tarsi in all the species comprised in the remaining two genera. In the genus *Eremiaphila*, the palpi are obtusely pointed, and the head is partially enveloped in the thorax; the two posterior pairs of legs are long and slender, and the thighs are sometimes terminated by a small spine; the penultimate segment of the abdomen is furnished with two spines in the females. The elytra and wings are always very short. The genus *Mantis* (as now restricted) is distinguished from the last by the head being free, the palpi very slender and almost pointed, and the wings as long as the body, or nearly so; the penultimate segment of the abdomen is never furnished with spines.



Mantis gongylodes. (♀.)

The Mantidæ are found in all warm countries, are exceedingly numerous, and remarkable for the grotesque forms which they usually assume. Their resemblance to a portion of a plant is often so great, that it is only by their motions they can be discovered. The names *religiosa*, *precaria*, *sancta*, &c., have been applied to certain species on account of a peculiarity in their habits—that of erecting the thorax at an angle with the body, and placing together the large fore-legs, like the hands of a person when at prayer; in this position they will sometimes remain perfectly motionless for several hours. Their food consists of flies and other insects, which they are exceedingly dexterous in catching by means of their fore-legs; the prey is held by the fore-leg by bending back the tibia against the femur; the opposing surfaces of these two portions of the legs being covered with spines, enables them to retain their prey in this manner, and to convey it to the mouth.

The eggs are deposited by the female Mantis upon plants, and are covered by a glutinous substance, which soon becomes hard and forms a kind of case, in which they are arranged in a symmetrical manner. The form of the case varies according to the species. The young, when hatched, resemble the parents, except in size and in being destitute of wings.

Mantis gongylodes has been selected to illustrate a common form of the insects of the present family. This species inhabits the East Indies, and when alive is most probably of a green colour. The female is about four inches, and the male is about three and a half inches in length.

MANTINEIA was situated in the east part of Arcadia, in an elevated plain of considerable extent, which was bounded on the north by the plain of Orchomenus, and on the south by that of Tegea. [ARCADIA.] The inhabitants of Mantineia originally dwelt in four or five separate districts (Xen., *Hell.*, v. 2, § 7; Strabo, p. 337); but were afterwards collected into one city. The Mantineans had a democratical form of government, and were closely connected with Argos. Their political constitution, which appears to have been partly framed by Nicodorus, a friend of Diagoras of Melos, has received great praise from Polybius and Ælian. (Pol., vi., p. 487, C. (Casaubon); Æl., ii. 22, 23.) Their form of government and their connection with Argos led them to oppose the Lacedæmonian interests. In B.C. 418 they formed an alliance with Elis and Argos against Sparta, but were entirely defeated and obliged to sue for peace. (Thucyd., v. 64-74, 81.)

In B.C. 385, the Spartans, suspecting the designs of the Mantineans, commanded them to destroy the walls of their city; and on their refusing to do so, the Spartans sent an army against the place, under the command of Agesipolis. Agesipolis took Mantineia by diverting the course of the river Ophis, which flowed through the city, and thereby causing an inundation, which undermined the walls. (Xen., *Hell.*, v. 2, § 1-7; Paus., viii. 8, § 5; Diod. xv. 5.) The city was then destroyed by the Spartans, the inhabitants compelled to live apart in four hamlets, as in antient times, and the form of government changed to an aristocracy. After the battle of Leuctra, the Mantineans again rebuilt their city; and it was in the vicinity of their town that the battle was fought, B.C. 362, between the Spartans and Thebans, in which Epaminondas fell. Mantineia, in later times, joined the Achæan league; but in consequence of the massacre of a garrison of Achæans, who had been placed in the town at the request of the inhabitants, the city was attacked and taken by the Achæans in connection with Antigonus Doson, who sold all the male population as slaves. In honour of Antigonus, the name of the city was changed to Antigoneia, which it retained till the time of Hadrian, who restored its original name. (Paus., viii. 8, § 6.) Pausanias, who visited this city in the second century, describes it as a large and flourishing place, and has devoted a considerable part of his eighth book to a description of its works of art.

The ruins of Mantineia, now called *Palæopoli*, are still considerable. Colonel Leake says, 'The circuit of the walls is entire, with the exception of a space of four or five towers on the eastern side; in no place are there more than three courses of masonry existing above the ground; and this height is so uniform, that one cannot but believe that the remainder of the works was constructed in sun-baked bricks, as it appears to have been when Agesipolis, by means of the little river Ophis, which flowed through the city, made an inundation, which submerged the foundation, and effected a breach in the superstructure. The facing only of the work is constructed with large wrought stones, put together without cement; the middle being filled up with a rubble of broken stones mixed with mortar; the inner lining was 2 feet thick, the outer 4 feet, the rubble 4 feet—total 10 feet. The form of the city was slightly elliptical, and about equal to a circle of 1250 yards in diameter, or 2¼ miles in circumference. The number of towers, if I reckoned right, is 118, the curtains are generally about 80 feet long, the towers 23 feet in the face and 13 in the flanks. There are ten gates, the approach to which was carefully defended. The entire circuit of the walls is protected by a wet ditch, formed by a small stream, which flows in from the east, and, embracing the city so as to make it an island, flows westward from the opposite extremity.' (*Travels in the Morea*, i., p. 103-105.)

MA'NTOVA, DELEGAZIONE DI, a province of the Lombardo-Venetian kingdom, is bounded on the east by Verona and Rovigo, on the north by Brescia and the southern bank of the lake of Garda, on the west by Brescia and Cremona, and on the south by the duchies of Modena and Parma. The province of Mantova is entirely in the great plain of Lombardy, and forms part of the basin of the Po. It extends on both banks of that river, a part, though only a small one, lying on the south bank. The other rivers of the territory of Mantova are the Mincio and the Oglio, both affluents of the Po. The Mincio issues out of the lake of Garda at Peschiera, and for about ten miles marks the limits between Verona and Mantova, after which it flows across the territory of the latter, forms the lagoon in the midst of which stands the city of Mantua, and then enters the Po below Governolo. The length of the province from north to south is about 36 miles, and its breadth is about 32 miles: the population, in 1837, was 257,234, distributed in 17 districts, 13 of which are north of the Po, viz. Mantova, Ostiglia, Roverbella, Volta, Castiglion delle Stiviero, Castelgoffredo, Asola, Canneto, Morgaria, Borgoforte, Bozzolo, Sabbionetta, Viadana; and four south of the Po, namely, Gonzaga, Revere, Sermide, and Suzzara. There is no town of any importance except the capital.

The territory of Mantova is noted for its fertility. It contains numerous fine meadows well adapted for the grazing of cattle, which are irrigated by numerous streams and canals; vines and mulberry-trees also abound. Landed property is very valuable in this district, which labours however under two disadvantages, namely, the danger of the inundations of the Po, to prevent which the dykes and gates are kept in constant repair at a great expense, and the unwholesomeness of the air in summer.

MA'NTOVA (or MANTUA), the Town of, is on an island about five miles in circumference, in the middle of a lagoon formed by the Mincio, and is joined to the mainland by causeways, the shortest of which is about 1000 feet in length. The town and its approaches are regularly fortified, and it is considered the strongest fortress of Italy. The town is well built, with wide streets and squares, and contains many handsome structures. The principal buildings are—1. The cathedral, one of the finest in Italy, with many excellent paintings, chiefly by pupils of Giulio Romano. 2. The church of St. Andrea, raised by the architect Leon Battista Alberti, of Florence, and adorned with paintings by Giulio Romano and his pupils, and with the mausolea of several distinguished persons, the painter Mantegna, the sculptor Sperandio, the botanist Donato, the poet Cantelmi, the philosopher Pomponacio, and other illustrious Mantuans. Giulio Romano himself, who, as painter, architect, and engineer, has enriched Mantua with numerous works of art, is buried in the church of St. Barnaba, but the tombstone, with an inscription over his grave, has been obliterated in reconstructing the church. The house of Giulio Romano, built by himself, is still standing. 3. The church of Santa Barbara, rich in paintings. 4. The public library and museum: the sculpture gallery, although little noticed, is next in value to those of Rome, Florence, and Naples; the library contains 80,000 printed volumes and many MSS. 5. The ducal palace, an old, vast, irregular structure, partly rebuilt by Giulio Romano, with some good paintings, which have been much injured during the various sieges and invasions which Mantua has undergone. The portraits of the antient dukes of Mantua were bespattered with lime in 1797 by the political fanatics of that time, who testified in this manner their hatred of princes. 6. The gates and bridges of Mantua, especially the gate dei Mulini, by Giulio Romano. 7. A palace outside of the town, called 'of the T,' because some say it is built somewhat in the shape of that letter, whilst others pretend that the name is derived from the dialect word 'tejetto,' which means a drain for the marshy waters with which the ground was encumbered. This structure was originally intended for stables for the dukes Gonzaga, but under the direction of Giulio Romano it grew into a vast palace. The same artist, with his disciples, painted the apartments, one of which is called the Hall of the Giants, and contains a representation of the defeat of that mythological race by Jupiter.

Two miles from Mantua is the village of Pictole, which a vague tradition reports to be the same as Andes, Virgil's birthplace. The dukes of Mantua had a palace here, called La Virgiliana, which still exists, though much dilapidated.

The town of Mantua contains about 25,000 inhabitants, independent of the garrison. It is a bishop's see, has a lyceum and a gymnasium. In 1833 the province contained one hundred and fifty-six elementary schools for male children, and ninety-seven for females. (Serristori, *Saggio Statistico.*) The Jews, who are several thousands in number in Mantua, have their own schools and a house of industry supported by themselves.

The origin of Mantua is lost in the obscurity of the ante-Roman times. Virgil (*Æn.*, x. 201) boasts of its Etruscan origin, its former power, and says it was inhabited by three different races; and Pliny the elder (iii. 19) observes that it was the only relic of the Transpadane Etru[illegible]s, from whom it passed into the power of the Cenomani Gauls, and afterwards became subject to Rome with the rest of Cisalpine Gaul.

After the fall of the Western empire it was successively subject to the Goths, the Longobards, the Franks, and the German emperors. In the twelfth century it asserted its freedom as an independent municipality, like the other Lombard cities, but afterwards became subject to native tyrants or usurpers. The remaining history of Mantua is given under GONZAGA.

MANTUA. [LOMBARDY; MANTOVA.]

MANU (a word which implies 'rational,' from *man* to 'understand'), according to a judicious Hindu fiction, was the son or grandson of the creating deity Brahmâ, the first of rational beings, and the progenitor of mankind, who thence are called Mânavâs, or Manujâs (offspring of Manu). To this primeval sage, the father of the human race, and consequently their patriarchal ruler and legislator, is ascribed a celebrated system of religious and civil law, which in the beginning of time was revealed to him by Brahmâ, and has been handed down by tradition to the present age. In other words, the Sanskrit work now extant, and indiscriminately called Smriti (tradition), or Mânavadharmasâstra (the Institutes of Manu), is deemed by the Hindus not only the oldest but at the same time the holiest text after the Vedas. Before these pretensions of the sacred code to antiquity and authority can be duly appreciated, it will be convenient to state its contents, and to point out the leading features of a system at once so comprehensive and so complicated that it would be almost impossible to dwell upon its particular precepts without entering fully into the labyrinth of Hindu religion and ceremonies. The work is divided into the twelve following chapters:—i., On the creation; ii., On education, or on the first order; iii., On marriage, or on the second order; iv., On economics and private morals; v., On diet, purification, and women; vi., On devotion, or on the third and fourth orders; vii., On government, or on the military class; viii., On judicature, and on law, private and criminal; ix., On the commercial and servile classes: x., On the mixed classes, and on time of distress; xi., On penance and expiation; xii., On transmigration and final beatitude.

We shall not dwell on the first or last chapter; the first is occupied with a summary of the contents of the whole code, and with a problem of cosmogony, in accordance with the wild and fanciful conceptions of Hindu metaphysics and natural philosophy; the twelfth chapter contains a detailed system of metempsychosis and final punishments, closely connected with the institutes of temporal law. It is obvious that either a strict order in the arrangement of the judicial code has been neglected, or, what is more probable, the monarchical and civil laws (vii.-xi.) have purposely been separated from the general duties contained in the first half of the work. These for the most part are of a religious character, being engrafted on the most rigid distinction of castes, and therefore totally dependent upon the hierarchical rules of the first order, by which even the minutest actions of the inferior classes are invariably to be regulated. Without entering into the mass of formalities and customs by which the main structure of the Brahminical, and in fact of every hierarchy is largely cemented, and into those generally absurd and often ridiculous ceremonies inculcated upon the different branches of society, it will be sufficient to remark that they were evidently congenial to the religious prejudices and to the nature and disposition of the Hindus, and that most of them had long been sanctioned when the sacred code was promulgated. This is expressly asserted by the author himself, who professes to give the system of law in its full extent, and the immemorial customs of the four classes, adding that immemorial custom is transcendent law, approved in sacred scripture; and that holy sages have embraced good usages long established. The principal duties of the four classes in general are stated as follows:—

To the first, or sacerdotal order, the supreme ruler assigned the duty of reading the Veda, and of teaching it; of giving advice to kings, of sacrificing and of assisting others to sacrifice, of giving alms and of receiving gifts, of promoting justice on earth, and of procuring happiness hereafter; in short, a Brahmin must ever be intent on divine worship, devotion, austerity, and abstinence. It is only in case of need that he is allowed to support himself by tillage or traffic, but never by service for hire. Although he is by right the chief of the whole creation, and, whether learned or ignorant, must be revered as a powerful divinity, nevertheless he should constantly shun worldly honour, and rather seek disrespect and poverty.

The Kshatriya, or military class, is bound to defend the people, to read the Veda, to sacrifice and to give alms; the Vaisya caste to cultivate land, to keep herds and flocks of cattle, to carry on trade, to lend at interest, to sacrifice, to read the scriptures, and to bestow presents. The business of the fourth, or Sudra class, is only to serve the three upper orders, and chiefly the Brahmins.

Now in these four classes, which may be called the pillars of Hindu society, those only who are born of wives equal in caste are to be considered as of the same class with their fathers. But by intermixture and marriage with women who ought not to be married, and by the omission of prescribed duties, a great number of impure classes have been formed, which in their turn are obliged to perform strictly the special rules and obligations enjoined on their caste, or else they will sink to a still lower degree in the scale of human society. These mixed classes are enumerated at large in the tenth chapter, and prove a far advanced state of civilization by the very great variety of professions which they exhibit. But as even the aboriginal tribes and the inhabitants of adjacent countries are asserted to have gradually sprung from the same source, we need scarcely remark that the institution of caste carried to this extent must be altogether imaginary; and moreover that a system of law founded on these vague and fanciful principles must be a partial and almost degrading one. Hence the punishments, consisting of pecuniary fines and confiscation of property, of mutilation of the body, and death, of exile and loss of caste (which is deemed moral death), are inflicted according to the privileges of the different classes; in general these punishments are slight and trifling for the highest order, but dreadfully severe and cruel for the same crimes when committed by an individual of inferior caste. Thus a soldier who defames a priest shall be fined a hundred panas, a merchant a hundred and fifty, but a mechanic or servile man shall be whipped; and while the slaying of a Sudra by a man of the sacerdotal class is exactly equivalent to the killing of a cat or dog, the murder of a Brahmin is an inexpiable crime, and he who barely assaults a priest with intention to hurt him shall be whirled about for a century in a place of future punishment, which is described as 'a dark hell.'

With regard to the penal provisions of the criminal law we shall only observe that in most of them the principle of retaliation has been sanctioned; for instance, whoever breaks a dam or sluice, by which an inundation would be caused (Buchanan, *Mysore*, i. 4), shall be drowned; an adulterer shall be burned on an iron bed; a cut-purse is to lose two fingers, and 'with whatever limb a thief commits the offence, even that limb shall the king amputate' (viii. 334; ix. 277, &c.). Nevertheless most of the punishments may be commuted for pecuniary fines; and in case a temporal chastisement proves unavailing, threats of future pain are often held out. A priest may by muttering imprecations and holy charms chastise those who injure him, without complaining to the king. In short the first part of the sacred code is entirely what we should call hierarchical. This character is apparent not only in its inflexible severity where religion and its ministers are concerned, and the well-calculated distinction of castes, by which a free intercourse between the members of society would be prevented and consequently a more close dependence on the priesthood ensured, but also in the spirit of sublime devotion, of benevolence and tenderness to all sentient creatures, by which sacerdotal institutes are generally distinguished.

The second part of the code, containing the monarchical and civil laws, is more congenial to social order, and although the same spirit of hierarchy prevails, it is often checked by rules of a sound policy and of regular administration. The king, born in the military class, is formed of particles drawn from the substance of the guardian deities; surpassing all mortals in glory, he is himself a divinity in a human shape, and consequently he must be the protector of all classes who discharge their duty (7, 4, 8, 391 ff.). 'He must invariably speak truth and never transgress the rule of strict justice; but as just punishment cannot be inflicted by an ignorant and covetous king, he has to learn the science of criminal justice and of policy, the system of logic and metaphysics and sublime theological truth from learned priests, and from the people the theory of agriculture, commerce, and other practical arts.' Nothing is so often and so strongly inculcated by Manu as the equity and justice of kings in protecting the property of their subjects against fraud and violence. For this purpose the prince shall appoint a governor of one town with its district, another of ten towns, of twenty, of a hundred, and above all these inferior authorities, a high officer, whom we may perhaps call a lord-lieutenant, over each thousand towns. Also, to prevent the people being oppressed, a superintendent of all affairs shall be established in every large town to inspect the inferior officers. A large number of laws for the mercantile tribe, with rigorous regulations about the sale and purchase of marketable things, about weights and measures, tolls and freights for boats passing up and down rivers; the severe punishment of robbers and of those who will not restore loans and deposits, and the most subtle definitions of the law of inheritance—all tend to show that, however restricted by the rules of caste the social and personal condition of an individual might be, his property at least was respected and held inviolable. As to the laws of succession, it is laid down as a fundamental rule, probably derived from ancient patriarchal manners, that, if possible, the whole property of the family should be kept together. Accordingly after the death of his father, the eldest son may take entire possession of the patrimony, and the others may live under him, unless they choose to separate. In this case, the widow and such persons as by crimes or mental and corporal defects are legally excluded from participation, being provided for, the heritage is divided into portions according to the minute and almost endless variety of regulations by which, owing to the real or imaginary intermarriage and mixture of classes, this part of Hindu law has become extremely abstruse and intricate. Property belonging to a sacerdotal student and to a minor must be guarded by the king, until the owner shall have concluded his studentship, or until his infancy shall have ceased in his sixteenth year. No tax is levied or charge made for this trusteeship nor for any tuition whatsoever; and except custom-duties and market-taxes, the only legal tax or annual revenue which a sovereign may receive from his whole dominion through his collectors is imposed on the mercantile and agricultural classes. He may take either a twelfth part of the crops, or an eighth, and in time of distress even a fourth part, but in every respect he must act like a father to his people (7, 80, 10, 118 ff.). Serving men, artisans, and mechanics never pay taxes, but they must occasionally assist by their labour when needed. According to a theory most rigorously supported in a rude state of feudal and despotic government, by several Hindu lawgivers of modern times, and even by a passage in Strabo, the king has been declared sole possessor of the soil (*Digest of Hindu Law*, i. 460; Strabo, p. 1030, *ἔστι δ' ἡ χώρα βασιλικὴ πᾶσα*). But although the sovereign's right to an annual ground-rent, and his gifts of land, so often recorded in inscriptions and written documents, may originally have been founded on such a doctrine, its practical application would have proved ineffectual, and in fact it is nowhere adopted nor even mentioned by the sacred code. On the contrary, it is expressly stated as a rule laid down by antient sages, that cultivated land shall be the property of him who has cut away the wood, or who has cleared and tilled it (9, 44). To prove the inviolability of the tenure of land, in which the proprietor is rather protected than limited by government, many special laws might be produced, such as those concerning landmarks and boundaries, the common ponds by which the fields are watered, the punishment inflicted on herdsmen and owners for injuring cattle; and so far is the agricultural tenant from being disturbed in his possession, that even if land be injured by his neglect, he shall only be punished by a heavier tax.

The most striking feature by which, on the whole and notwithstanding its many glaring defects, this code is distinguished, is the rigour and purity of its morals. A complete system of ethics might be gathered from the scattered moral sentences, of which we subjoin the following few examples. 'Let not a man be querulous, even though in pain; let him not injure another in deed or in thought, let him not even utter a word by which his fellow-creature may suffer uneasiness (2, 161). Let him bear a reproachful speech with patience; let him speak reproachfully to no man; with an angry man let him not in return be angry; abused, let him speak mildly (6, 47). Let him say what is true, but let him say what is pleasing; let him speak no disagreeable truth, nor let him speak agreeable falsehood (4, 138 ff.). Though oppressed by penury, in consequence of his righteous dealings, let him never give his mind to unrighteousness (4, 171); let him be firm in his contentment and check all desire of acquiring more than he possesses, for happiness has its root in content, and discontent is the root of misery (4, 12). A wise man should constantly discharge all the moral duties, though he perform not constantly the ceremonies of religion (4, 204); he should act without any view of reward, and constantly shun religious hypocrisy, for he who describes himself to worthy men in a manner contrary to truth is the most sinful wretch in the world; he is the worst of thieves, a stealer of minds (4, 255). Even here below an unjust man attains no felicity, nor he whose wealth proceeds from giving false evidence; for the soul itself is its own witness: offend not thy soul, the supreme internal witness of men. The sinful have said in their hearts, "No one sees us." Yes, the gods distinctly see them, and so does the spirit within their breasts (4, 170, 8, 84). He who perseveres in good actions, in subduing his passions, in bestowing gifts, in gentleness of manners, who bears hardships patiently, who associates not with the malignant, who gives pain to no sentient being, obtains final beatitude (4, 246; 12, 10). Single is each man born, single he dies, single he receives the reward of his good, and single the punishment of his evil deeds. When he leaves his corpse, like a log or lump of clay on the ground, his kindred retire with averted faces, but his virtue accompanies his soul' (4, 240). The principal moral duties in general are summed up in the following passage: 'The avoiding of all injury to animated beings, veracity, the abstaining from theft and from unjust seizure of property, cleanliness and command over the bodily organs, form the compendious system of duty, which Manu has ordained for the four classes' (10, 63). To conclude with the words of Sir William Jones: 'The work contains abundance of curious matter, extremely interesting both to speculative lawyers and antiquaries, with many beauties which need not to be pointed out, and with many blemishes which cannot be justified or palliated; it is a system of despotism and priestcraft, both indeed limited by law, but artfully conspiring to give mutual support.'

The time at which the laws of Manu were composed is wholly uncertain, and it was only from conjecture that the eminent Sanskrit scholar whom we have just named fixed the twelfth century B.C. as the probable epoch of their composition. Generally speaking we may safely pronounce it the code of an already refined and enlightened people, and the work itself bears ample testimony that a very advanced degree of civilization had been acquired by the Hindus when these laws were promulgated. For producing every article of luxury an immense variety of professions would be required. And as a Sudra deciding causes of law, and even a Sudra-king, are mentioned (4, 61; 8, 21), and as king Vena is censured for having given rise to a confusion of classes (9, 66), it would seem that the order of things was then nearly the same as in modern times, in which, according to the remark of a judicious observer, 'every profession, with few exceptions, is open to every description of persons, and the discouragement arising from religious prejudices is not greater than what exists in Great Britain from the effects of municipal and corporation laws.' (Colebrooke, *Remarks on the Husbandry and Internal Commerce of Bengal*, Lond. 1806, p. 174; Rickards's *India, or Facts submitted to Illustrate the Character and Condition of the Native Inhabitants*, London, 1828.) Even intellectual culture is found to have made considerable progress: the Vedas are written, and must be read, with accents and letters well pronounced; heretical books are mentioned (2, 11), legal questions must be decided by arguments and rules drawn from local usages and from *written* codes (8, 3), and written edicts of kings were by their frequency liable to forgery (9, 232). But after all, and what is most important, the burning of widows is totally unknown: on the contrary, a widow is legally bound to devote herself to pious austerity, and may even be lawfully married to the brother of her deceased husband, as she could marry any other man during the reign of king Vena (3, 173; 5, 157). Now the duties of a Satti, so minutely detailed in works of later date, could not possibly be omitted in a sacred code of law, and therefore the work seems at least anterior to the invasion of India by the Macedonians, who were fully acquainted with these horrid sacrifices.

The learned Hindus agree that many laws enacted by Manu were confined to the first three ages of the world, and have no force in the present age; some of them have been abolished or modified by subsequent Hindu lawgivers, according to whom the work is rather to be honoured than to be strictly followed. In fact for a long time it has formed only a very small part of the juridical system, and may be considered as the oldest text-book of law extant, or as the Hindu 'Institutes,' preparatory to the copious 'Digests,' 'Pandects,' and other legal works now in use among the different juridical schools in India. (Ellis, in *Madras Transactions*, vol i., and Sir Thomas Strange, *Hindu Law, principally with reference to such portions of it as concern the Administration of Justice in the King's Courts in India*, Lond. 1830.)

The 'Institutes' of Hindu law, or the 'Ordinances of Manu,' were verbally translated from the original by Sir William Jones, 1794. The Sanskrit text with the gloss of Kullûkabhatta was published at Calcutta in 1813, and a new edition of the metrical text, together with Sir William Jones's translation, carefully collated with the original, was prepared by Sir Graves Haughton, 1822, 1825. Another valuable edition, with select notes and a French interpretation, by Loiseleur des Longchamps, was published at Strasburg in 1830.

MANUCODIATA. [BIRDS OF PARADISE, vol. iv., p. 420.]

MANUEL, NICLAUS, who claims notice not only as an artist, but as a poet and author, and one who took an active part in the Reformation in Switzerland, was born at Bern in 1484. His real name is conjectured by his recent biographer, Dr. Grüneisen, to have been Alleman, but as he was illegitimate, it was, for family reasons, changed anagrammatically into that of Manuel. It is further conjectured that he was brought up by his maternal grandfather, Thüring Frickart. Having made choice of painting as a profession, he studied the art at Colmar, under the successors of the celebrated Martin Schön, until the fame of Titian attracted him to Venice, where he became one of his pupils. This period is fixed by his biographer about the year 1511, at which time he was married. He is said to have assisted Holbein, in 1515, in his 'Dance of Death;' yet this is very questionable, because he was himself employed at that time in painting the same subject at Bern, which he executed in fresco in the cloister of the Dominicans. He also ornamented his own house with a large fresco, representing Solomon worshipping idols. But of these and several other of his works nothing now remains except some small water-colour copies preserved in the library at Basle. It seems however that his pencil did not bring him sufficient for the maintenance of his family, on which account he resolved to try to advance himself in military and public affairs. He served, as quarter-master or commissary, among the Swiss allies who assisted Francis I. in his expedition against Milan, 1522, and was present both at the storming of Novara and the battle of Bicocca. In the following year he was chosen landvogt of Erlach; and from the year 1523 distinguished himself by his zeal in the cause of the Reformation. From this period he was entirely devoted to that cause, and to his various public employments. He died in 1530, when only 46 years of age.

As a writer he began to distinguish himself in 1509, by various popular poems and songs in the Swiss dialect, full of humour and sharp satire. His 'Fastnachtspiele,' or Dramatic Moralities and Mysteries, which he began to compose about 1522, are marked by the same qualities; in which, as may be almost taken for granted, his polemical pieces in support of the Reformation were not at all deficient.

MANUEL, FRANCISCO, one of the most eminent of the modern poets of Portugal, was born at Lisbon in 1734. His first study was music, but he afterwards devoted himself entirely to literature, and more especially to poetry, his talent for which obtained him many admirers, and also some enemies and persecutors. His enemies accused him not only of entertaining exceedingly heretical opinions, but of openly professing his contempt for the church, alleging against him his arguments in favour of toleration, his free remarks on the monks, and, not least of all, his translation of Molière's 'Tartuffe.' Being summoned to appear before the Inquisition, instead of obeying the mandate of the Holy Office, he attacked and disarmed the agent sent to apprehend him, and saved himself by immediate flight to Paris, in 1778; in which city he resided till February 25, 1819, when he died at the age of eighty-four.

Though a zealous cultivator of the purest models of Portuguese literature and poetry, Manuel was a no less ardent admirer of the classics. His veneration for the writers of antiquity was in some degree injurious, inasmuch as it led him to regard them rather as models invariably to be followed, than as studies upon which a sound poetical taste is to be formed. And to this predilection for the poets of antiquity is to be ascribed his dislike to rhyme. Nevertheless his merits and excellencies are undeniable; and it has been said of him that no *Portuguese* poet or writer since the time of Camoens did so much for the language, in which respect his services were more valuable than those of a whole academy. He excelled in lyric and satiric poetry, and among his productions of the former class his odes to D'Albuquerque and Washington are deservedly admired for their sublimity and grandeur. Many of his epistles, tales, and fables are also stamped by merit, though of a different kind. The services which he further performed for Portuguese literature were very considerable, for he produced admirable versions of Wieland's 'Oberon,' 'Silius Italicus,' Châteaubriand's 'Martyrs,' and La Fontaine's 'Fables.' Like his original compositions, these translations are distinguished by singular purity of style, carried occasionally perhaps rather too far, as his horror of Gallicisms and new-coined expressions frequently led him to adopt obsolete words, which carry with them something like an appearance of pedantry and affectation.

MANUMISSION. [LIBERTINUS; SLAVE.]

MANURE. Every substance which has been used to improve the natural soil, or to restore to it the fertility which is diminished by the crops annually carried away, has been included in the name of manure. Thus chalk, marl, clay, and even sand, when added to the soil for the purpose of improving its texture, have been called manures; and some confusion has arisen in our ideas in consequence of applying the same word to signify things which are essentially different. The French have a term by which they distinguish the substances which merely improve the mechanical texture of the soil from those which act more directly in nourishing the plants which grow in it. The former of these they call *amendements*, and the latter *engrais*. For want of another word there might be no impropriety in adopting the first of these, instead of the vaguer term of 'improving manures,' retaining the word 'manures' for those which are considered as stimulating or nourishing, and which are usually called enriching manures.

It is well known to all practical agriculturists that the texture of the soil and the proportions of the earths of which it is composed are the first and most important conditions of its productive powers. Where there is a good natural loam which retains moisture without becoming wet or overcharged with it, and permits the influence of the atmospheric air to pervade it, the crops cannot fail to be more certain and remunerating than in loose sands or tenacious clays, however rich they may be in those substances which are supposed to supply the elements from which the juices of plants are chiefly composed. But at the same time it is equally true, that the best texture of soil will not produce good crops for any length of time, without the help of dung or other rich manures to recruit the loss produced by vegetation.

The various means of improving the texture, such as tillage and the mixture of earths, are treated of separately. [LOAM; MARL; SOIL; TILLAGE.] We shall here confine our observations to that class of manures which stimulate or enrich the soil.

There are some substances which evidently belong to both classes of manure. Of these lime, either in its caustic state of quick-lime, or its milder form of a carbonate or chalk, is the principal. Lime, being an earth less porous than sand, and more so than clay, has an improving effect on soils in which either sand or clay prevails; but it has also a chemical effect as an alkaline earth, and, considered in this light, it acts on the soil in a peculiar manner, and greatly assists the effect of enriching manures, which are all of animal or vegetable origin.

Lime as a manure acts most powerfully in its caustic state, that is, when deprived of the carbonic acid which is generally united with it. The carbonic acid is expelled by the heat of a furnace or kiln, and limestone or marble is by this means reduced to the state of quick-lime. The water of crystallization, which makes the particles of marble or limestone adhere in a solid form, is driven out by the heat which reduces it to a light porous stone, very readily pulverized, and having so strong an attraction for moisture and carbonic acid, that, if it be left exposed to the atmosphere for any length of time, it absorbs both from it, and gradually returns to the state of hydrate and carbonate, or lime united with water and carbon, with this difference, that it is now a fine impalpable powder, instead of a hard stone.

Lime newly burnt has a peculiar effect upon all organic matter, which it burns or dissolves by taking from it a portion of the water and of the carbonic acid which it contains. On humus, which is the result of animal and vegetable decay in the earth, it has a peculiar effect, rendering it soluble in water, and thus fit to enter the minute fibres of the roots of plants. This circumstance is probably the secret of all the wonderful effects of lime on certain soils, while it appears almost inactive in others. In some places, where the soil is peculiarly poor, being evidently a pure siliceous sand washed by the sea or by rivers, lime is found to do no good; but on the rich alluvial clays, which contain much organic matter, it is the best of manures, both in a caustic and mild state.

Caustic lime readily unites with the half-decomposed fibres of vegetable matter, such as straw, heath, and the like; it helps their decomposition and accelerates it; by its means the dead fibres of the roots of vegetables, which remain in the earth when the plant is removed, become soluble; and their elements, entering into new combinations, supply the materials for the various vegetable substances which are naturally produced. As long as there is a store of organic matter or humus in the soil, lime will be an excellent manure; as soon as this is exhausted, it will only add to the sterility by destroying every fibre which the seed might throw out from its own substance by the assistance of light and moisture. This will account for the various reports which have been made at different times of the effect of lime when put on land. In some instances the quantity which might be safely used appeared almost unlimited, in others a very small portion exhausted the powers of the soil.

Agricultural experiments are seldom conducted with sufficient precision. The man of science in his study operates on a minute portion of soil, and his experiments on vegetation are carried on at best in a few feet of garden-ground. The farmer is occupied with too many things to mark the minute differences which affect the results. Where lime has been found useful, and a good crop has been obtained by the abundant use of it, land is limed as often as can be done, with the same expectation of success. The same may be said of chalking and marling: if one application has done good, another, it is supposed, will be equally beneficial. On the same principle the quack doctors pretend that their medicines not only cure the diseased, but should also be taken continually by persons in health to prevent disease. The ignorant only are the dupes of these pretensions. Lime is a most excellent manure, and, when properly applied, most beneficial; but it may become inert, or even noxious, when applied injudiciously.

The property to which lime owes its chief power in promoting vegetation is, its combining with certain elements of decayed animal and vegetable matter, and forming a compound which is soluble in water, and which attracts carbonic acid and moisture from the atmosphere. This substance is readily taken up into the sap by the fibres of the roots, and supplies the plant with oxygen, hydrogen, and carbon, which are the elements of all vegetable substances, if we except a few which also contain nitrogen, one of the component elements of the atmosphere. Thus we see that air, water, and carbonic acid are sufficient to afford all the elements of vegetables, and that the use of the lime is chiefly to facilitate the absorption of these elements, besides depositing a very minute portion of the pure earth in certain parts of the vegetable. Thus far lime acts as a solvent, in the same manner as alkaline salts, which, in a much smaller quantity, would have the same effect. The alkalies are seldom used as manure in a pure state, but they abound in ashes, sea-weeds, and all woody fibres of vegetables; and when these are used as manures, the alkali produces its effect. Lime, being so much more abundant, and obtained at comparatively little cost, is preferred. But lime, besides its effect on the humus in the soil, acts also on the clay which it may contain; and where this is abundant, its effect is most beneficial. For this purpose it need not be in a caustic state; and chalk, which can be used in much greater quantity, from its abundance in many parts of England, effects a much more permanent improvement in the soil. But chalk acts also chemically wherever acids exist in too great abundance, whether they be mineral or vegetable: it neutralizes these acids, and in doing so generally gives out some of the carbonic acid which it is combined with: and this, before it is quite expanded into gas, is readily taken up by the moisture in the soil and carried into the vessels of the plants, where it deposits the carbon, letting the oxygen escape by the pores of the bark and leaves.

Where limestone is abundant, and the burning of it is expensive, it is sometimes broken and pounded fine: in this state it is of great use in stiff soils. At first it acts merely mechanically, as fine sand would do; but gradually pulverising and meeting with acids, its chemical effects become apparent.

The use of quick-lime in rendering inert vegetable fibres soluble, and hastening the decomposition of animal substances, is of the greatest importance in agriculture. Substances may be rendered highly enriching in a short time, which, without it, would have lain long dormant in the soil or the dung-heap. Its effects in this way will be more particularly noticed when we treat of composts.

Wherever there is peaty matter in the soil, which, owing to the tannin principle which it contains, is, by itself, perfectly incapable of putrefaction, lime is the true remedy. Assisted by fæculent matter to produce a degree of heat and fermentation in it, lime soon dissolves peat and converts it into real humus, than which there is no better food for vegetation. The ashes of burnt peat act in a different way; they contain alkaline salts and earths in a state of minute division. They do not furnish any substance from which a plant derives its chief increase in bulk, but they serve to prepare other substances in the earth and convert them into manure. They have also some effect in stimulating the action of the vessels which elaborate the different juices, as culinary salt has on the stomach of most animals. At least there is every reason to think so from analogy in the absence of positive proof. From all this the practical use of lime, chalk, or ashes is readily deduced. In a very stiff clay, chalk or lime will render it much more porous, and admit the influence of the atmosphere; it will correct acidity and assist the nutritious effects of animal and vegetable manures. Quick-lime spread on a soil abounding in vegetable matter will make it active by dissolving the half-decomposed fibres and converting them into a soluble mucilage: being extremely minutely divided by its property of attracting moisture rapidly, a very small quantity produces an immediate effect. Hence it is generally spread over fallows or clover-leys, which are preparing for wheat-sowing. If it were put on the land long before the seed is sown, it would have lost its chief power by attracting carbonic acid and returning to the state of carbonate or chalk, and all the expense of burning would be thrown away, except as far as it has thoroughly pulverised it. But frost does this with chalk spread before winter at a much cheaper rate; and a good dressing with chalk will last in the soil, and its effects be preserved, many years after all the lime would have disappeared. It is therefore a matter of mere experiment and calculation whether it be more profitable to put ten waggon-loads of chalk on an acre of stiff clay, or one or two waggon-loads of quick-lime. If the soil be very tenacious, the chalk will probably be the most profitable in the end as well as the cheapest; but for a few crops the lime may appear to have the advantage. Everything depends on situation, and the comparative facility with which lime and chalk can be procured.

On poor sands chalk will be found to produce a greater and more permanent improvement than the same value in lime, which, unless it be mixed with clay or vegetable substances, will not be of great use on such soils. When marl can be procured, or clay and chalk, these will be the best correctives for the porous nature of sand, whether mixed by nature or artificially. But marls are chiefly amendments, and as such will be noticed separately. [Marl.]

The substances which have generally been used as manures are numerous and various, and have been divided into stimulating and nourishing manures. All saline substances are ranked under the first, and all organic matter under the second.

When ignorance sheltered itself under vague terms, the fertility of the soil was attributed to the general term 'salt' or 'nitre,' both very undefined substances, which led to errors instead of promoting the investigation of truth by observation. Nitre was supposed to exist in dews, rains, and snow. All vegetables were supposed to consist of salt and earth, or more properly of soluble and insoluble substances, and on this uncertain foundation theories were built and practices recommended. It was said that when the soil was fallowed it imbibed nitre from the atmosphere, because it was known that animal and vegetable matters decomposing in a heap of earth gradually produced nitre, which, although it did not actually absorb it from the air, was certainly generated by combining the elements of atmospheric air with the alkali which existed in the organic matter; and, as the earth from which the nitre was extracted was an excellent manure, from the remaining portion of organic matter in it, it was supposed to be the effect of the nitre which remained. That nitre may be of use in some cases we will not deny; but there is not the slightest foundation for believing that it is the real pabulum of plants, or that the soil owes its fertility entirely to its presence.

From the most accurate analysis of the component parts of plants, it is ascertained that salts and earths form a very inconsiderable portion of their substance, and that carbon and water furnish by far the greatest part. The nitrogen of the atmosphere is found only in some of them, and all metallic substances seem entirely adventitious.

It has been supposed that all the carbon in plants might be supplied by the atmosphere, but this is not supported by any proof; on the contrary, plants will not thrive, unless there be in the soil in which they grow substances which contain carbon, that is, chiefly animal and vegetable substances, and chalk. The two first readily part with it, but the latter retains it too strongly to lead us to conclude that the plants draw any of it from this source, unless where a stronger acid is present to release the carbonic acid by its greater affinity to lime. We may conclude then, that from whatever source the oxygen and hydrogen of vegetable substances are derived, the carbon comes from the decomposition of organic substances, either animal or vegetable, and that these, in a certain state of decomposition, afford the supply of carbon by which the plant increases and secretes its juices. As in the animal digestion the chemical affinities, as observed in the raw materials, seem all to be set at defiance, or greatly modified by a vital energy of that organ, so in the conversion of the simple vegetable sap, differing but little from pure water, into the various substances which are produced by vegetation, no analogy can be drawn from the experiments of the laboratory. Nature alone has the secret of transmutation, and it is only by watching her operations and endeavouring to imitate them, that we can hope to come to useful practical results.

These preliminary observations are necessary to the consideration of the comparative importance of various substances used as manures.

The first and most important class of manures are the excrements of animals. The peculiar property of earth in absorbing putrid effluvia and removing disagreeable smells, appears an indication of nature to lead us to bury putrid animal substances, of which the excrements and dead carcases of animals are the most numerous and obvious. It would require no length of experience to show that wherever this is done vegetation is more vigorous. There is therefore another motive for burying dung than merely to get rid of a disagreeable substance. From the most ancient times of which there are any records, the dunging of a field has been an important part of cultivation. The preparing of the dung of animals, so as to render it more efficacious, is a later improvement, and has not yet attained the perfection of which it is capable, unless it be so in China, of which we read wonderful accounts. The fresh dung dropped on the ground, far from improving the herbage where it has fallen, appears to injure it, and render it unfit for cattle to eat; when it gradually disappears, and not till then, the spot is restored to its former verdure. But if the dung is dug into the ground and covered with earth, the fertilizing effect will be immediately perceived. This is a sufficient lesson to the husbandman to make him bury the dung as soon as possible. But this not being always practicable, it is collected in heaps until it can be carried to the land prepared for its reception by ploughing or digging. By mixing the straw, which has served as litter to cattle, with their dung, the quantity is increased, and by allowing this mixture to heat and putrefy, a greater quantity of manure is produced. This is probably the history of the dunghill. Science has seldom been applied to show the most profitable mode of collecting dung and forming a dunghill; but experience has, in many countries, taught methods which accord well with what science might have taught. The manure must be soluble before it can be effective; this solubility can only be produced in the more solid portions, such as the straw, by putrefaction, which the dung promotes when duly moistened. All well-managed dunghills are therefore watered in dry weather, and turned over to let every portion undergo the same degree of putrefaction. The exact moment when it is most advantageous to bury it in the ground seems not yet fully decided. Some let the decomposition go on until a great portion of the heap is converted into a black, tough, oily substance, which, from early association, gives the idea of richness. It is no doubt a powerful manure which acts speedily, but is it the most economical? This may be disputed. A great portion of the substance must have been resolved into gases, which fly off and are lost. The remainder, evidently carbonaceous from its colour, has acquired too much of the appearance of charcoal to be very efficient; and it is only the exuding juice which is immediately fertilising. The most experienced farmers agree, that whenever the brown colour of a dungheap verges towards a black, the dung has lost something of its value, besides the diminution in its bulk by dissipation. The best state in which dung can be carried to the land is, according to the best informed practical agriculturists, when the straw is so rotten that it readily breaks into short pieces, without having entirely lost its form: it should then be of a brown or mahogany colour, uniform throughout the mass. Whenever dung is mentioned by foreign agricultural writers, it is generally understood to be in this state, which in English is called short dung.

As manure is wanted for the land at different seasons, it is of consequence that the dung from the yards and stables should be collected in such heaps, and managed so as to be in the exact state which is thought most advantageous at the time when it is carted on the land. To effect this some attention is required. The oldest portion must have its putrefaction retarded, and the newest accelerated, to bring them both to the same state. This is easily done. If a certain thickness of dung is kept trodden down by the cattle, it will be a long time before it decomposes, nor will it do this without being turned over to expose the under portions to the air. If, on the contrary, it be carried out into a heap in a loose state, and occasionally turned over and moistened when it appears dry, it will heat and be ready in a very short time. When a sufficient quantity of short dung can be carried to a field prepared to receive it, and immediately ploughed in with a shallow furrow, it will soon incorporate with the soil, and afford a succession of soluble humus or mucilage, which will give regular nourishment to the plants. This is said on the supposition that the soil is in that state when it only requires manuring, and has a texture favourable to the crops raised upon it. In poor sands or wet clays some modification in the state of the dung may be necessary.

In speaking of dung, we have not said anything of the different kinds of dung produced from different domestic animals. In some cases it may be advantageous to keep these separate; for instance, the dung of cows from that of horses, of cattle feeding on oil-cake or grain, with or without turnips, and those fed on straw or refuse hay only. Cow-dung, when in a fresh state, is thought best for light soils, and horse-dung for cold heavy soils. The richer the dung, from the nature of the food given to the animals, the less of it need be used, and this may be worth attending to. But in general a mixture of the dung of all the different animals kept on a farm with all the straw that can be afforded, will give a manure of an average strength, which may be used upon all kinds of land; with this difference, that for light soils it should be more decomposed than for the heavy, and also ploughed in deeper; for the air penetrates the light soil to a greater depth, and sooner acts on the manure. In heavy land the straw, if not so much decomposed, will form cavities to let in the air, and allow of a more regular evaporation. All this is well known to most farmers, but not always strictly attended to. It is better to manure slightly and often than to put on a large quantity at once, except for some particular crops, which require a rich earth and consume much manure, such as potatoes, beet-root, and ruta-baga, or Swedish turnips, whatever some authors may write to the contrary, led away by the old notion that roots impoverish the soil less than seeds, which is not universally the case. Any one who has raised the above-mentioned roots with the usual manuring, and drawn them off the land to be consumed elsewhere, will acknowledge that his subsequent corn was far inferior to that which had succeeded beans, tares, or clover, with the same quantity of manure. Those who do not agree in this opinion may readily be convinced by a fair trial.

The chief use of cattle on an arable farm, besides those which are necessary for the operations of husbandry, is to produce manure for the land. If the cattle repay their food and the expense and risk attending their keep, the manure is sufficient profit. Even with a moderate loss, they must be kept, when manure cannot be purchased; and a portion of the land must be cultivated solely for the maintenance of cattle. In some poor soils one-half of the land is not too much to produce manure sufficient for the other half. The loss, if any, on the cattle must be repaid by the increase of the corn crops. Manure is to a farm what daily food is to an animal; it must be procured at any sacrifice. It is better to let land remain uncultivated in rough pasture, as was once the case with a great part of Britain, and is still the case with extensive tracts on the Continent, than to break it up without having the means of manuring it. A few crops may be obtained at first, but the land is deteriorated for ever after, and what has been obtained from it is dearly paid for.

Various means have been adopted to increase the quantity and efficacy of manure. The simplest is to increase the number of cattle, and husband their manure. It is evident that to let cattle run in loose pastures is a great loss, not only on account of the dung which is dropped, and more than lost, but also the urine, which contains the very essence of manure. In all countries where stall-feeding is practised, the lands are highly manured, and the crops more certain and abundant. With this system is connected a much more economical management of the manure, by keeping the litter and more solid parts of the dung separate from the urine and liquid parts, which are collected in large reservoirs, and used either in the liquid state, and applied immediately to the land, or in the formation of compost heaps, with earth and vegetable substances collected for the purpose, and the straw which has served for litter. As this is a subject not generally known and seldom carried into practice in Britain, we will dwell a little upon it, availing ourselves of the information obtained from other countries, particularly from the husbandry of Flanders, of which an account has been published in the Farmer's series of the 'Library of Useful Knowledge,' Nos. 105, 106, and 107.

When the urine and a considerable portion of the solid dung are washed into a reservoir immediately from the stables, its strength can be much more readily ascertained than when they are mixed up with straw and thrown into a yard. The specific gravity of the liquid is readily ascertained by an instrument, and those who are in the habit of observing this liquid manure can judge most accurately of its strength, and of the degree of putrefaction which it has undergone.

Notwithstanding some apparently contradictory opinions, it is pretty generally acknowledged by those who have had long experience of its use, that urine and similar animal substances have a more powerful effect on the soil, when they have undergone a certain degree of putrefaction, than when they are used in a fresh state, and that this is produced with the least loss of substance when the liquid has been confined in close vaulted cisterns which admit the external air only partially. On light soils this liquid has a most fertilising effect, if it is used frequently in small portions at a time. On very heavy soils this effect is not so apparent, and for such soils the liquid is accordingly mixed with sand or any light earth before it is applied; or, instead of using it at once upon the land, it is poured over the litter, which has been collected in a heap or in a yard, after having served for the cattle. This litter, having been deprived of the urine which would otherwise have mixed with it, would rot very slowly and produce a very inferior kind of manure, unless it were moistened, and fermentation were excited by pouring the half-putrefied urine over it. It may be objected that if the urine is only collected to moisten the straw which has served as litter, it would be as well to let it be mixed at first, without the trouble of pumping it up and the expense of a cistern to hold it. But we shall soon see that there is a very wide difference. In the common mode of collecting farm-yard dung, the straw is very unequally impregnated with animal matter: at one time it will contain a large portion and run rapidly into fermentation; at another, there will be so little, that it is with difficulty that heat is excited in it. By separating the urine and litter, the straw will go much further, and can be mixed with the urine at the most advantageous time; thus it forms a much richer manure in a smaller compass, from not being so much diluted with water. Should there be a deficiency of straw, earth or sand will supply its place, in as far as soaking up the rich juices; for the addition to the manure from the decomposition of the straw itself is very small in proportion to that which animal juices afford. If the liquid is collected from a stable or a yard where cattle are kept as soon as it is produced, and is carried off into a cistern, there will be a much better and drier bed left for the cattle, especially if the rain is kept off by light shades. When the litter is soiled to a certain degree, it may be removed to a heap in a proper place, where its conversion into rich dung may be effected by the addition of putrefying urine, than which nothing will so soon rot vegetable fibres, if the air be admitted to the heap. The portion which is not wanted for some time may be left to decompose more slowly; and as the time approaches when it is wanted for the land, it may be managed so as to be in that state which experience has shown to be most effective in the improvement of the crops.

There is some appearance of certainty and regularity in this mode of making a dunghill, which there scarcely is in the common practice of accumulating straw, dung, and urine without any regularity in a farm-yard, turning it over when the cattle leave it for the pastures, and carrying so many cart-loads per acre on the land to be manured, without any measure of its comparative strength. One portion is often almost burnt black, and another appears like the fresh litter of the stables, not being even thoroughly soaked with moisture. It is true that good farmers pay more attention to their dung-heaps, and endeavour to carry out the manure in a proper state; but how much more readily would this be accomplished by the help of a large cistern full of the richest animal matter in a state of partial putrefaction. In those situations where straw bears a high price, it may be doubtful whether a cistern might not permit a considerable profit to be made by the sale of a portion of the straw, without any diminution of the manure required for the farm, since for light soils the liquid might be used alone, and for stiffer soils it might be mixed into a compost with earth, chalk, and any kind of refuse vegetable matter of less value than straw. It was an opinion expressed by a celebrated agriculturist* to the writer of this article, that he considered the use of straw in dung to be merely as a sponge to hold the liquid animal matter in its pores or tubes. In fact, straw or old thatch merely rotten by long exposure to air and moisture is of little or no value as a manure, although it will sometimes produce good potatoes, by rendering a stiff soil pervious and porous; but, in a light soil, a gallon of urine is worth ten times its weight of rotten straw. This doctrine may appear strange to some agriculturists, but it will bear the test of experiment.

The great use of liquid manure on light soils is to impregnate them with soluble matter, which, being diffused through their substance, supplies nourishment to the roots of plants, wherever they may shoot out. It may be applied to the land at any time before the seed is sown, and soon after, when the blade springs up or the seed begins to form; in short, whenever the plant requires fresh nourishment, or when that which existed in the soil is diminished. Without liquid manure, the poor silicious sands of Flanders could never be cultivated, much less produce crops which vie in quantity and quality with those on the best soils. The quantity of farm-yard dung, in a very rotten state, which this soil would require according to the common system of manuring, could never be produced by all the straw which can be raised upon it in its first state of cultivation. But cattle produce urine, and this produces roots for cattle. The great effect of liquid manure has set the farmers on finding some artificial substitute for the simple urine and diluted dung of cattle. Such substitutes are obtained by mixing all kinds of refuse animal matter with water, and inducing putrefaction. The emptyings of privies from towns is scarcely a substitute; for it is the same as the liquid from the stables in a more concentrated form; but the refuse of oil-mills and various manufactures, when diluted and mixed with a portion of putrid urine, soon become assimilated to it. This becomes a branch of trade in those countries where nothing will grow without manure, and is a resource where an increasing population demands the cultivation of inferior soils to supply the necessary increase of food, as well as an increase of produce from those which are naturally fertile.

The increase of manure by the formation of *composts* is well known in many parts of Britain, and by their means the land has in many districts been rendered much more productive. The fundamental principle upon which composts have been made, is that of impregnating portions of earth with those parts of the dung of cattle, which, from want of management in the common dunghills, would have been dissipated and lost; and also accelerating or retarding the decomposition of animal and vegetable substances by the addition of earths, such as chalk, marl, clay, and even sand, according to the nature of the soil on which the compost is to be used. All solid manure which is to be ploughed into the ground should contain certain parts already soluble in water, which promote vegetation: while other portions should be in a progressive state, so as to afford a succession of soluble matter by a gradual and slow decomposition. Though we have set forth the value and importance of liquid manure, and suggest the best mode of applying it, we would guard against its being supposed that solid dung may be altogether superseded by liquid. Liquid manure, however active and immediately effective, soon loses its power; whereas solid dung, well prepared and ploughed into the ground, will last for several crops. It is the judicious use of both these manures, conjointly, which has the best and most permanent effect. The dung or compost, having been ploughed in well, requires some time before it can have any direct effect on the germination of the seed or the nourishment of the plant. The liquid, on the contrary, acts from the moment it is poured on the surface. It is the milk of the young plant, which thrives upon it and stretches out its fibres through the earth, till it reaches the dung, which, having undergone that slow transmutation which forms humus, is now in a proper state to supply the more vigorous roots with sufficient nourishment. It is evident that the growth must be more rapid and regular, and not so liable to be checked from want of proper nourishment, nor are the young roots in danger of perishing by being too soon exposed to the immediate contact of rank dung. Every exertion should therefore be made by the industrious husbandman to increase the quantity and improve the quality of every species of manure both solid and liquid: and here careful experiment can alone be depended upon. Sir Humphry Davy, who so much enlarged the sphere of chemical science by his discoveries, hastily asserted that the dung from the stables and yards should be buried in the soil as soon as possible, because when it is collected in a dunghill a great portion of volatile and gaseous matter escapes into the atmosphere. But he did not proceed to show whether the ammonia or hydrogen which escapes would have been of any use in the soil, perhaps this exhalation, instead of diminishing the value, or even the bulk of the manure, actually improved it. It does not appear that fermenting dung produces carbonic acid, for a man may sleep on hot dung without much danger, which would not be the case if much carbonic acid were evolved; the ammonia is produced in the very first stage of decomposition, as may be perceived in opening the door of a stable where horses have been shut up for some time; but a heap of manure does not produce the same effect when its first heat is gone off. Most observant practical farmers have followed a contrary practice, and let their dung be tolerably short and rotten before it is ploughed into the soil. The Flemings pour liquid manure on the small heaps of dung in the field, to excite fermentation before they spread it and plough it in; some, on the other hand, let the manure remain spread over the soil, rolling it in order to pulverise it some time before it is ploughed in. Without pretending to decide between these opposite practices, we will venture to affirm that, until more light is thrown upon the process of vegetation and decomposition, the sure experience of the farmer is more trustworthy than the most plausible theories of men of science, unless they are supported by numerous and accurately conducted experiments on a large scale.

---

* Mr. De Fellenberg, of Hofwyl, near Bern, in Switzerland.

In the formation of composts the principal objects are, to regulate the decomposition of the organic substances, and to increase the bulk of the manure by means of less expensive materials than straw. For these purposes lime or chalk is generally used; the former, in its caustic state, to accelerate the decomposition of fibrous matter; the latter to add to the mass, and absorb any portion of acid, which is always produced in a certain stage of the fermentation. The mode of doing this is so generally known, that it is needless to describe it: we shall only observe that the stiffest clay may be used with advantage in composts, where better soil is not at hand; and for light lands, the stiffer the clay the better, provided it be thoroughly incorporated with the manure. The most useful material, under proper management, is peat or turf. This may be laid in layers with quick-lime and earth; the whole being well soaked with liquid manure. If any kind of vegetable matter, such as fern, broom, the tops of heath, or pond weeds, can be added, it will be so much the richer. The lime and urine, acting on the peaty matter, decompose its tannin and transform it into humus, the woody fibre is dissolved, and the whole mass, when turned over and well mixed, becomes a very rich earth, which, being spread on the land and slightly ploughed or harrowed in, greatly enriches its surface. By this means many poor soils may be improved, where the cultivation is not sufficiently extended to produce straw. Potatoes grow readily in peaty soils which are drained and limed; and the potatoes when given to cattle will produce sufficient dung and urine to improve the land without much straw being used.

As a substitute for urine, several mixtures of animal and saline matters have been tried, which are supposed to resemble it in composition. There is no reason why such a liquid might not be formed artificially, and if it can be made with cheap materials, which may be obtained in abundance and at less expense than by keeping cattle, it would be a very important discovery.

Although bones have been treated of in a separate article [BONES], it may be proper to mention here, that if some easy means of dissolving their substance were discovered, they might be made of much greater use than they now are. At present they are put in with the seed in a broken state, and as they remain a long time undecomposed in the soil, their effect, after the first crop, is scarcely perceptible, unless a very large quantity is used. By mixing dissolved bones in a liquid state with earth, almost all the component parts of urine would be there.

Experiments have been made on the subject of artificial liquid manure by Mr. Kimberley of Trotsworth farm, Surrey, and we understand the result will shortly be made public by subscription.

The various substances which are generally enumerated, as occasionally used for manure, are chiefly the refuse of manufactures, consisting of earths, salts, and organic substances. Soapers' waste is chiefly lime with a small portion of alkali. The scrapings of leather, horn, bones and the refuse of the shambles, the hair or wool of animals, and rags made of these, may be all classed together. They must be distinguished as acting in a twofold manner; they absorb and retain moisture, at the same time that they afford nourishment by their gradual decomposition. Hence the great effect produced by them on certain plants, such as hops, and the length of time during which this effect is perceptible, especially in dry porous soils.

It is generally supposed that animal and vegetable manures produce their effect by giving nourishment to plants out of their own substance. This is no doubt true; but it appears also that they have a power of absorption, by which they attract not only moisture but also oxygen from the atmosphere, and probably hydrogen by the decomposition of the water. Thus the elements are at liberty to form new combinations, which are assisted by the vital action of the roots. This throws no great light on the subject, but it may be kept in mind, to prevent erroneous conclusions being drawn from the result of imperfect experiments, and to put us on our guard against applying the general principles of chemistry to the composition and use of manures without carefully attending to all the circumstances and watching all the appearances. We would recommend to all practical farmers to note down every particular in the formation and application of the manures which they employ, and also their apparent effect. It will require some years to enable a man to draw just conclusions, but the data will thus be established, and more will be discovered by such a course than by all the experiments which can be made on a small scale.

There is one substance which has been highly extolled as a manure, but which is scarcely known by name in English agriculture. This is called *urate*, being a compound of urine and plaster of Paris. It is formed by mixing sand and burnt gypsum with urine, and forming a hard compound, which is afterwards reduced to powder. The Royal Society of Agriculture at Paris caused some experiments to be made with this manure for the purpose of comparing it with those which are known to be most effective, such as dried nightsoil, pigeons' dung, &c. The result was in favour of the urate for the duration of its effect on lucern in a light soil, where the portion manured with the urate produced the greatest return at the third and fourth cuttings, when the nightsoil and pigeons' dung had lost a portion of their effect. It requires a moist season to act powerfully. When mixed with dried nightsoil its effect on various crops was very great. But it does not clearly appear whether this is to be ascribed to the urate chiefly, or to the dried nightsoil. Its effect on potatoes was superior to that of the dried nightsoil. It might be worth while to repeat these experiments, which may be found detailed in the *Dictionnaire d'Agriculture Pratique*, in 2 vols. 8vo., Paris, 1828. If it should furnish a substitute for bones, it would be very valuable, as it could be obtained to an almost unlimited extent from large towns.

The ashes of vegetable substances which have been burnt in the open air contain a great portion of potass, with some fine earths. They are consequently very effective in stimulating vegetation on lands which contain a good portion of humus. They are chiefly used as a top-dressing on young clovers and grasses; and wherever there is an appearance of sourness in the grass wood-ashes are of great use. It is however seldom that wood-ashes are used as manure until the greater part of the alkali has been extracted; but when the surface of the land is pared off and the dry sods are burnt, the ashes which result from this operation are very effective in producing a good crop without any other manure. [PARING AND BURNING.] The refuse ashes from bleachers' and soap-boilers' premises have still some portion of alkali in them, and as they contain lime and other earths in a very divided state, their effect on the soil is very perceptible. Sea-salt has been extolled and decried at different times, owing probably to the different circumstances under which it has been tried. In a very small quantity sea-salt may have a beneficial effect on the soil. Urine contains a great deal of it, and in the formation of composts sea-water has been found to hasten the putrefaction of the animal and vegetable matters which they contained, probably by absorbing moisture, which is essential to putrefaction. Quick-lime slaked with sea-water and mixed with sand forms a mortar which attracts moisture so strongly that walls built with it are scarcely ever dry. This suggests a mode of supplying the soil with moisture, and may account for the effect of salt in particular cases.

The experiments which have hitherto been made on artificial manures have not been sufficiently varied to lead to any very accurate conclusions as to their comparative merits, and the results have not been stated with the minuteness which would make them a foundation for practical rules. There is a wide field open to the chemist and the scientific agriculturist, and many important discoveries no doubt would be the result of patient and accurate investigation.

MANURING, in horticulture, requires to be considered in a somewhat different light from that process as applied to agricultural purposes. This is necessary because of the variety of plants, possessing different constitutional habits, to which the gardener is required to turn his attention, and also because of the different results which are expected in horticulture and agriculture. In preparing the present article the writer has confined himself to simple practical facts, and has adverted only occasionally to chemical explanations. In the present state of our knowledge of that branch of inquiry, improved as it is since the time of Davy, opinions are still too vague and unsettled to afford the cultivator a satisfactory solution of the physical problems suggested by the commonest facts in the art of manuring.

The gardener is called upon to cultivate species from almost every kind of soil on the surface of the globe, intermediate between the shifting sands of the desert and the most fertile alluvial land continually enriched by the decay of vegetable and animal substances. It is therefore obvious that considerable caution is requisite in applying manure and in determining the quantity or quality suited to the respective constitutions of the various subjects which the horticulturist takes under his care. Thus, although many plants can scarcely receive too much manure, others, such as the resinous trees, are actually killed by it.

The kind of manure chiefly used, and frequently the only kind procurable by the gardener, is that derived from the farm-yard; consisting chiefly of the dung of horses or of horned-cattle, more or less mixed with litter. Formerly it was very generally the custom to take advantage of the heat resulting from the fermentation of such dung in hot-bed forcing, and there are still some objects for which this kind is found preferable [HOT-BED]; but since the hot-water system of heating has received so many improvements, the continued fermentation and consequent degree of decomposition which dung undergoes in hot-beds is rendered a less important means of obtaining artificial warmth, and consequently it becomes the more important to inquire whether manure is most beneficially applied in a state of decomposition, as some have advocated, or in a state as recent as possible, no fermentation being permitted previous to its deposition in the soil.

It is said that rotten dung contains more *humin*, weight for weight, than fresh dung. But the experiment, in order to be just, would require to be tried with two equal quantities of fresh dung, one of them being analyzed at the time, and the other after being subjected to the requisite degree of decomposition; for the latter process will of course occasion a diminution of weight, which ought to be taken into account. If the fertilising power of manure can be proved to be in proportion to the quantity of *humin* which it contains, and if the quantity of this be as great as in the more bulky form of unrotten dung, the concentrated state would certainly be preferable, in point of economy, on account of the saving in labour and carriage; but in the present state of knowledge this cannot be asserted, and until theories become reconciled with each other, and with experience, the latter must form the only safe guide in practice.

If dung contains a large proportion of litter, and particularly if the latter be in a dry state, it will be advisable to subject it in nearly all cases to a moderate degree of fermentation, assisted by a sufficient quantity of moisture, in order that the fibre of the straw may be reduced into a state permeable by the spongioles of plants, and either become sufficiently dissolved for affording nourishment itself, or serve in the first instance as an absorbent reservoir for substances of still greater solubility. Where such preparation has not been attended to, litter has been frequently observed, when turned out of the ground after a dry summer, to be still in a dry musty state, having evidently been of little benefit to the crop; and in the case of many plants, which require much manure, litter in this state would actually prove very injurious. But if the dung be what is termed short, containing little straw, and that well saturated with the liquid proceeds of the stalls, it may be dug in without fermentation for most kitchen-garden crops, provided it is well divided and properly mixed with the soil in digging or trenching in. This is necessary in all cases, but more especially so when the manure is applied fresh; for disease is often induced by the roots entering into masses constituted of particular substances which either wholly or, at all events, too powerfully predominate over the proper nutritive solutions.

But on the other hand, if the soil is of a wet and stiff nature, then long unrotted dung is most proper, because its straws form so many minute drains which, to speak technically, keep the ground open; and in such soils, by means of littery manure and drilling, a crop of potatoes, for example, can be raised very superior in quantity and quality to that obtained from the application of rotten dung. In this case the previous reduction of the fibre of the straw is not requisite; for the moisture of such soils is sufficient to effect this by degrees, and whilst the process of growth is going on. The authority of Miller may be adduced on this subject; in his 'Gardener's Dictionary,' he observes, 'In very cold moist land, I have frequently seen new horse-dung buried as it came from the stables, and always observed that the crops have succeeded better than where the ground was dressed with very rotten dung.'

On the other hand, dung that has been moderately fermented, and frequently turned over, so as to be easily cut with a spade, is the most proper for such trees as require manure, or for slow-growing crops, where the roots have to remain for years in contact with it. If the heat arising from fermentation do not exceed 100° Fahr., Sir Humphry Davy considers that but little loss will arise from the process. With regard to trees and many perennial plants, no more injury would be incurred by using fresh dung instead of rotten, for the first season, or rather whilst vegetation continued active; but after the roots become nearly dormant, canker or disease of some sort is apt to ensue. The roots may have grown luxuriantly during the summer; but when they are arrested by the approach of winter, decomposition will still be going on amongst the materials on which they feed, and these materials may perhaps be chemically changed, at all events vitiated for the purpose of nourishment, before the roots are again called to action.

These remarks relate chiefly to the description of manure which is most generally used. Other substances which are or may be successfully applied to promote the growth of vegetation are exceedingly numerous; and although it would be impossible to particularise them, they may nevertheless be made sufficiently known by stating that they consist of—

1. All animal substances without exception.
2. The excrementitious secretions of all animals.
3. All kinds of vegetable substances, in one state or another.
4. A few mineral substances, of which one of the principal is lime.

Animal substances are very powerful manures, and require to be attenuated or diluted before plants can derive nourishment from them, or in fact before either roots or tops can be safely brought within their contact. If the roots of a plant be wholly immersed in oil or in blood, that plant will be destroyed. Blood is one of those liquid manures which is occasionally supplied to plants so situated as to render bulky manure inapplicable; but it should unquestionably be copiously diluted with water. Oily manures, such as blubber for instance, which will not dilute with water, must be divided by earthy matter or other substances, by which means a large surface will be exposed to atmospheric agency. Oil is impervious to air and water; and it may be taken as a general rule, that all substances impervious to these elements are unfit for the purpose of vegetable nourishment, and must therefore be subjected to some mode of decomposition in order to render them available. Supposing a mass of oily substance equal to one cubic foot were isolated, the surface exposed to the oxygen of the air (by which soluble matter in such substances, according to Sir Humphry Davy, is produced) is 864 square inches. If however this mass be separated by any substance sufficiently porous to admit air, such as earth, the air will pervade every interstice, and the requisite decomposition will be rapidly brought about. Bones are another form of animal matter much employed, and of considerable energy, especially in calcareous soils, provided they are reduced into small fragments and fermented before being used. Gardeners often use them in that state for forcing strawberries, and, reduced to dust, as a top-dressing for lawns.

The liquid portions of excrementitious manure likewise require either to be diluted with water or to receive an admixture of soil before they are brought in contact with the roots of plants. In the case of trees with roots lying deep in the ground, such dilution is not always necessary; but, generally speaking, adherence to the rule is advisable.

Sir Humphry Davy recommends covering dead animals with five or six times their bulk of soil mixed with one part of lime. This, when mixed, it may be observed, will still form a very strong manure, and for some plants much too strong; but for such as the vine it will form a valuable compost, particularly if broken bones are mixed with it.

Manures derived from the vegetable kingdom require little preparation if they consist of such plants as are chiefly parenchymatous, such as the brassica tribe; their substance is easily soluble, and they may therefore be turned fresh into the soil. The period of their growth when this is most beneficially performed is before they run to seed. Weeds may even be used with great advantage, if properly prepared; but bad consequences may result from their seeds rendering the ground foul, and thus occasioning much expenditure of labour to extirpate them again. Seeds, it is well known, will not germinate without air; but with this, and sufficient heat and moisture, nothing can prevent them from germinating. Therefore if weeds be thrown into a heap and turned, whilst at the same time fermentation is encouraged till the heat is fully equal to that which would naturally cause the germination of the seeds, taking care that the outside be turned into the centre, no danger will arise from using such manure after the process has been continued sufficiently long for the germination of the slowest vegetating seeds which the heap may contain, because under these circumstances the young plants will be continually perishing as the heap is turned over from week to week. There are many aquatic plants that will not grow on dry ground, and a preparation similar to the above is not essential for the purpose of killing their seeds before their application to dry ground, which is not, as it were, their proper element.

Yeast is a most powerful vegetable manure, especially if employed in a state of putrefaction; but it requires to be diluted with water till it appears of the colour of very small beer. Applied in that state, it has extraordinary power in stimulating the growth of annual crops of all kinds; but its effects are by no means permanent; for lawns however it is a restorative manure of great value. The same may be said of malt-dust.

It is observed by Sir Humphry Davy that mere woody fibre seems to be the only vegetable substance that absolutely requires fermentation to render it nutritive to plants; and he instances tanners' spent bark as a substance very absorbent and retentive of moisture, yet not penetrable by the roots of plants; or it might rather have been said, not capable of affording nourishment, from the predominance of some noxious principle, which requires to be decomposed; for when this principle is broken down by fermentation, plants, as may be observed in bark-beds, root very readily in tan. This deleterious principle is the tannin which bark contains, and the reason of its noxious effects upon plants is that it precipitates the azotized matter in which roots abound, and the presence of which, in an organisable state, is indispensable to the existence of roots. (Payen, in *Ann. Sc.*, new series, iii. 19.) Inert peaty matter is a substance of the same kind, and will remain for years exposed to air and water without undergoing change. When peat becomes inert, it is in vain to attempt to grow any sort of plant in it; but nothing is more certain than that if drained of stagnant moisture and mixed with lime and dung, it will become very fertile for most crops. It often happens that peat or *bog-mould*, frequently procured at a great expense for American plants, becomes inert; in such cases, a good result would be obtained by turning out the peat and mixing it up in a heap with a quantity of leaves or fresh litter sufficient to promote a moderate degree of fermentation; then, as in the case of tan, it will afford nourishment, and will, from a state of uselessness, become valuable.

Of mineral manures, *lime* is the most useful. It is not recommended for soils that contain a large proportion of soluble vegetable matter; but it produces excellent effects in such as abound in inert vegetable fibre. Gypsum, which is found in the ashes of grasses, proves a manure for lawns.

Common salt is sometimes employed in minute portions, especially in combination with vegetable matter, in the instance of sea-weeds, in which case it is found of good quality for fruit-trees and kitchen-garden crops; but vegetable life is certainly destroyed by it, if applied in any considerable quantity. Exceptions may be noticed in the case of marine plants; the Samphire (Crithmum maritimum), for example, requires it when cultivated in inland districts; and this is also true of the vegetable inhabitants of the great salt plains of Asia. Wood-ashes, which consist principally of vegetable alkali united to carbonic acid, are a good manure, but of short duration, and they leave peaty soil in a worse state than before their application. The burning of such soil cannot therefore be too much reprehended, although strongly advocated by some who have been led away by the immediate result of one or two enormous crops. The application of dung and lime, of composts of clay, marl, scourings of ditches, &c., would render peat *permanently* fertile, more especially so when draining is judiciously attended to.

There is no considerable number of plants to which manure is prejudicial. Coniferous species of all kinds are affected most injuriously by it, and it requires to be given very sparingly to all trees which yield gum in their bark, especially stone-fruits, such as cherries, plums, peaches, and nectarines. To many however it appears to be useless; orchidaceous plants for instance, which it is now the fashion to cultivate so extensively, seem insensible to its application in any form yet thought of; and American plants in general scarcely require it, unless the peat in which they are grown be regarded as a kind of manure.

MANUSCRIPTS. [PALÆOGRAPHY.]

MANU'ZIO, ALDO, born in 1447, at Bassiano in the Papal State, studied at Rome and at Ferrara. He became intimate with Pico, count of Mirandola, and with Alberto Pio, lord of Carpi, with whose assistance he established a printing-press at Venice. The art of printing was first introduced into Italy from Germany by two Benedictine monks, called Sweinheim and Pannartz, who printed the works of Lactantius in the monastery of Subiaco in 1465. This was the first book printed in Italy. In 1469 two other Germans from Speyer established printing-presses at Venice, and soon after the art spread rapidly through Italy. The first Greek book was printed at Milan, and the first Hebrew types were used at Soncino near Cremona. Nicholas Jenson, a Frenchman, established a printing-press at Venice in 1471, which was distinguished for the elegance of its types. But Aldo Manuzio surpassed all other printers of his time in the correctness of his books. Being a man of learning as well as a printer, and having an extraordinary zeal for his profession, he procured the most correct MSS. from distant countries, and he established an academy in his house, with the view of obtaining assistance in the superintendence of his publications. Bembo and Navagero were among the members of that society. The first publications of Aldo appeared about 1490: the first with a date in 1494. In this year he published the poem of 'Hero and Leander' in Greek and Latin, and shortly after the Grammar of Lascaris, and that of Gaza, with Theocritus, and the works of Aristotle. He invented a new sort of type, which was light and resembled writing, called by the Italians 'corsivi,' and known to other nations by the name of 'Italic.' In this type he printed the Latin classics. A list of the Aldine editions was published at Padua in 1790: 'Serie delle edizioni Aldine per ordine alfabetico e cronologico;' and a still more complete catalogue has been since published at Paris by Renouard: 'Annales de l'Imprimerie des Aldes, ou Histoire des trois Manuces et de leurs éditions,' 2 vols. 12mo., 1803; a second edition of which, in 3 vols., was published in 1825, and a third, much improved, in one vol. 8vo., Paris, 1834. It is said that the Greek books of Aldus are less correct than his Latin and Italian prints; but it must be recollected that his Greek books are often printed from a single MS., and that an imperfect one; a circumstance however that renders some of his Greek books very valuable at present, as being tolerably faithful transcripts of MSS. either now lost or not always accessible. These editions, especially when upon large paper, have often sold in modern times for considerable sums.

Aldo complains in several of his prefaces of the difficulties which he experienced, and the intense labour which he had to undergo in his profession, to which he devoted his whole life. He died at Venice in 1515, with the well-merited reputation of being not only an accurate printer, but a good scholar. He was the author of a Latin and Greek Grammar, a Greek and Latin Dictionary (the first of its kind), and several other works. His son Paolo Manuzio succeeded him in the direction of his printing establishment. Paolo was a man of learning, an author, and a critic. His principal works are: 1, 'Antiquitatum Romanarum liber de Legibus,' fol. 1569; 2, 'De Comitiis Romanorum;' 3, De Senatu Romano;' 4, 'De Civitate Romana;' besides notes and commentaries on Cicero's Epistles and Orations.

MAP (Latin, *mappa*, a napkin; French, *mappemonde*, a map of the world).

A map is a representation of the surface of a sphere, or a portion of a sphere on a plane. The name however is commonly applied to those plane drawings which represent the form, extent, position, and other particulars of the various countries of the earth.

Maps or delineations resembling them we may reasonably conclude were coeval with the earliest geographic knowledge, for we can scarcely conceive such knowledge to exist in a nation at all without being accompanied by some attempts at illustrations, however rude and defective, by means of linear representations on a plane surface. It is not possible indeed to fix the time of these first attempts to construct maps, but there is good reason for supposing that the Israelites were not altogether ignorant of the art; for we find Joshua commanding his selected men in the following terms: 'Ye shall therefore describe the land into seven parts, and bring the description hither to me, that I may cast lots for you here before the Lord our God.' (*Josh.*, xviii. 6.) This knowledge of the Israelites was most probably derived from the Egyptians. The geographical knowledge of the Greeks, as exhibited in the Homeric poems, comprehended only a small part of Europe, Asia, and Africa, and there is not the slightest allusion in them to any mode of delineating or representing the surface of a country. In the seventh and sixth centuries before the Christian æra, and even earlier, we know that the Greek nation was widely diffused by colonization, which, combined with their spirit for commercial enterprise, must have greatly extended their geographical knowledge. In their maritime adventures they are said to have been assisted by the nautical maps of the Phœnicians; but however this may be, we have no account of anything deserving the name of maps before those of Anaximander the Milesian, who is alleged to have been the first to construct a map of the world. There is a passage in Herodotus (iii. 136) which may perhaps indicate something like an attempt at mapping a coast. Certain Persians, being commissioned by Darius I., sailed from Sidon in Phœnicia to the coasts of Hellas, which they examined and 'registered,' or 'recorded' (ἀπεγράφοντο), till they arrived as far as Tarentum in Italy. The map of Aristagoras of Miletus is also deserving our especial attention, from its being so particularly described by Herodotus (v.), and from its likewise being among the first maps on record, at least in Greece. Aristagoras, in his interview with Cleomenes, king of Sparta, on the occasion of soliciting his assistance against the Persians, is described as appearing before Cleomenes 'with a tablet of copper in his hand, upon which was inscribed every known part of the habitable world, the seas, and the rivers.' Notwithstanding the imposing character of this description, some have thought that we should not receive it too literally; and that this map was probably nothing more than an itinerary of the country between Sardis and Susa. Itinerary maps of the places of encampment were almost indispensable to the commanders of armies; Diognetus and Beton are mentioned (Pliny, *Nat. Hist.*, vi. 17) as the surveyors of the marches of Alexander, who was very careful in examining the measures of his surveyors, and in obtaining his descriptions from the most skilful persons. The science of geography made rapid advances under Eratosthenes [ERATOSTHENES; GEOGRAPHY], who had the great merit of reducing geography to a regular system, and of founding it upon solid principles. He introduced into his map a regular parallel of latitude, which he accomplished by tracing a line over certain places whose longest day was observed to be of the same length. This parallel extended from the Strait of Gibraltar to the mountains of India, passing through the island of Rhodes; and from its central position with respect to the principal antient nations, it became a standard of reference in the maps of this period. Succeeding geographers made many attempts to determine the longitude of places by measurements of this line, but with no great success. Eratosthenes, in addition to the parallel above mentioned and other parallels, undertook to draw a meridian from Meroe through Syene to Alexandria (Strabo, ii. 114), and also to determine the earth's circumference by the actual measurement of a portion of one of its great circles. These discoveries and improvements very materially affected the dimensions of all the antient maps; and from this time the connection between astronomy and geography was so far established as to ensure an advantage to the latter by every advance of the former. This was eminently the case in the discoveries of Hipparchus, who fixed the construction of maps on a mathematical basis, and enabled the geographer to lay down his latitudes and longitudes upon certain principles.

To Strabo we are chiefly indebted for our information respecting the state of geography in the Augustan age. But the extent of the earth's surface known to this writer does not very much exceed that which was known to Herodotus four centuries earlier. His map of the world exhibits some remarkable errors. He supposed the Pyrenees to run north and south; cuts off the projecting province of Brittany from France, places Ireland not to the west but to the north of Britain, and makes the Caspian communicate with the northern ocean though Herodotus had accurately described it as a lake.

The Roman Itineraries show that their surveys were made with considerable care, although there are no traces of mathematical geography in those which have been handed down to us, the chief object in view being the clear direction of the march of their armies. All the provinces of the Roman empire had been surveyed when Ptolemy composed his system of geography, which has happily been preserved to us. It is not so much to his more perfect acquaintance with the earth that Ptolemy owes his reputation as a geographer, as to his giving solidity and unity to the science by fixing its unconnected details on a mathematical basis and carrying into full practice and to greater perfection the system of latitudes and longitudes of Hipparchus, whose invention had been much neglected for upwards of 250 years.

Ptolemy derived his information respecting the distances of places chiefly from itinerary measurements which usually exceeded the truth, and it is therefore not surprising that his map of the world should exhibit enormous errors; in addition to which consideration it cannot be supposed that he possessed real astronomical observations sufficient to determine all the latitudes and longitudes which he has given. It was not possible therefore that he should have been free from great mistakes, more especially in places beyond the Roman empire.

Some idea may be formed of the errors in his map from the circumstance of the northern coast of Africa being represented by him nearly as a straight line, the gulfs of the Great and Lesser Syrtis almost totally disappearing, and the Mediterranean being extended twenty degrees beyond its actual limits, which gross inaccuracy was continued in our maps until the middle of the seventeenth century. He also placed the mouth of the Ganges 46° to the eastward of its true position.

It seems not improbable that the maps found in the MSS. of Ptolemy are really copies of, or derived from, original maps constructed by him or under his care. [AGATHODÆMON.]

Some curious particulars have come down to us illustrative of the geographical ignorance of the middle ages, yet maps do not appear to have been uncommon even then. The maps of the middle ages may be generally classed as follows:—1st, those in which the notions of the antients were adhered to; 2nd, those which exhibited new discoveries or countries popularly believed to exist. Many maps of the first class are extant in which the old world is represented as one great island, Africa terminating to the north of the equator. Among maps of the second class are those which seem to show some important discoveries in the west of Europe and of Africa in the twelfth and thirteenth centuries.

The geography of the Arabians is but imperfectly known. Their most eminent geographer Edrisi or Eldrisi, who lived about the middle of the twelfth century, divided the world into seven climates from the equator northward, and each climate was again divided into eleven equal parts, from the western coast of Africa to the eastern coast of Asia, the inconvenience of which arrangement is very obvious.

Towards the middle of the seventeenth century several astronomers undertook to observe eclipses of the moon with a view of correcting the errors in the longitude of places. These observations however were so discordant as to lead to no satisfactory result. Galileo, by the discovery of the eclipses of the satellites of Jupiter, introduced a more certain method, which was rendered available by means of the simultaneous observations of Picard and Cassini at the observatories of Uraniburg and Paris.

Picard and De Lahire were then immediately employed in correcting the map of France, and from this period our maps have rapidly improved. The great perfection to which timekeepers have been brought, and the obvious application of these machines to the determination of the longitude, have greatly contributed to their accuracy. But notwithstanding the advanced state of our astronomical and geographical knowledge, and the science and skill displayed in our great national and other surveys, we may, with Dr. Blair, regard maps as works in progress—always unfinished, and still waiting the corrections to be supplied by the science and enterprise of succeeding ages.

Having thus briefly sketched the progress of map-making, we proceed to give a general outline of their application and construction.

On the Nature and Construction of Maps.—Maps, being plane representations of the surface of a sphere, may be obviously applied to various purposes; hence we not only have terrestrial maps to represent the surface of the earth, but celestial or astronomical maps to represent the sphere of the heavens; and these general distinctions have again their subdivisions.

There are two kinds of terrestrial maps—geographic or land maps, and hydrographic or sea maps: we shall confine our attention principally to the former; the latter, which are usually called charts, having been already described. [CHART.]

Geographic maps, as already noticed, are those which represent the forms and dimensions of the several parts of the earth, with their relative situations and the positions of the cities, mountains, rivers, &c., comprised within their limits. They may comprehend the whole earth, or one of its larger divisions, or a single district, and are called maps of the world, general maps, or particular maps accordingly. If they give the nature of the ground, the roads, buildings, &c., in detail, they become topographic maps, which, necessarily embracing a very small extent of country, are not usually referred to any spherical projection, but are represented as geometric planes, the objects in them occupying the positions severally assigned to them by the trigonometrical operations of the survey. The same distinction is made in charts of small bays and harbours. In either of these cases they are called plans.

When maps of the earth are made to illustrate any of the sciences, they are distinguished from geographic maps, properly so called, and bear their own peculiar names, as geological, or mineralogical, or botanical maps.

From the spherical form of the earth, it is obvious that the divisions and varieties of its surface may be most simply and most accurately represented by means of a globe, and in order to obtain a correct notion of its general geographic features, there is no mode of representation so satisfactory. Large globes however are expensive and inconvenient instruments, and small ones, by not admitting sufficient detail, are for most geographic purposes entirely useless. Hence we see the eminent utility of maps, notwithstanding the imperfections which necessarily accompany such a mode of representation, for a spherical surface can by no contrivance be extended into a plane without a distortion of some of its parts.

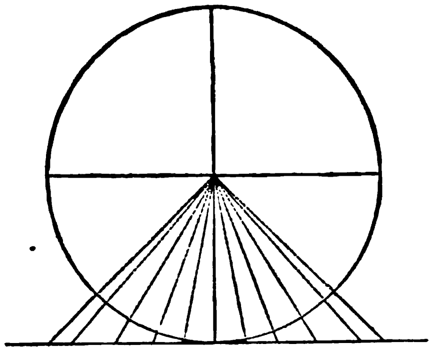
The methods adopted in the construction of maps are as various as the taste and judgment of geographers themselves, but they may all be referred to two principles, viz. *Projection* and *Development.*

By *Projection* is meant the representation of the surface of a sphere on a plane, according to the laws of perspective. By *Development* is to be understood the unfolding or spreading out of the spherical surface on a plane. This however first supposes the sphere to be converted into a cone or a cylinder—these being the forms, portions of which most resemble portions of a sphere, and which, at the same time, are susceptible of the required development.

We shall notice these two principles very briefly, as their mathematical investigation more properly belongs to the article PROJECTION.

There are four methods of spheric projection in general use, the *Gnomonic* or *Central*, the *Orthographic*, the *Stereographic*, and the *Globular*, distinguished from each other by the different positions of the projecting point in which the eye is supposed to be placed.

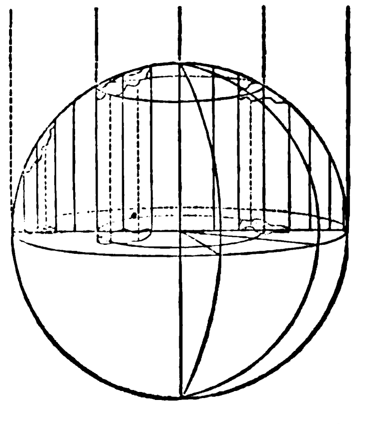
The *Gnomonic* or *Central Projection* supposes the eye to be placed in the centre of the sphere, and that the various objects to be delineated are transferred from the sphere to a plane, which is a tangent to its surface. The entire hemisphere can never be represented by this projection, since the circumference which terminates it is on a level with the eye, and is therefore parallel to the plane of projection. This method is chiefly used in dialling, but may be advantageously applied to maps of a limited extent, more especially if they are maps of the polar regions of the globe. In this case the meridians will be strait lines radiating from the centre, and the parallels of latitude concentric circles, whose distances from the centre will respectively be equal to the cotangents of their latitudes.



In the other cases of this projection, where the perspective plane is parallel to the horizon, or to any meridian, the construction is rendered troublesome on account of the parallels of latitude becoming curves of difficult delineation: these cases therefore are seldom brought into use.

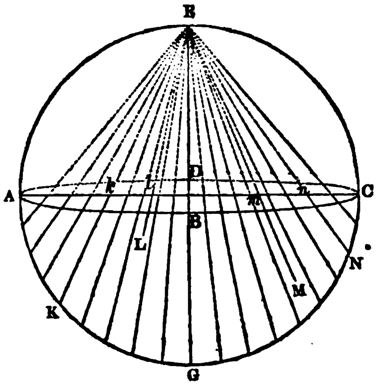
Orthographic Projection.—In this projection the eye is supposed to be at an infinite distance, so that the visual rays leave the sphere in parallel lines. The perspective plane on which a hemisphere is supposed to be delineated is the plane of that diameter which is perpendicular to the visual rays—hence every point of the hemisphere is transferred to this plane by perpendiculars let fall upon it. It will be immediately seen from the figure, that the representation will decrease in accuracy with the increase of distance from the centre; the parts near the circumference being much foreshortened and distorted.

In a *Polar map* of this projection, the meridians, as in the Gnomonic maps, will be radii, and the parallels concentric circles; these circles however will have their distance from the centre equal to the cosines, and not to the cotangents of their respective latitudes.



In an *Equatorial map*, or one in which the equatorial regions of the globe are made to occupy the centre of the map, the plane of projection coincides with the plane of one of the meridians. In this case the latitude circles will be projected in strait lines parallel to the equator, which is also a strait line, and will vary in distance from it according to the sines of their respective latitudes. The meridians will be portions of ellipses intersecting the equator in points similar in position to the intersecting points of the parallels on the polar diameter, and having their transverse axes coincident with this diameter and equal to it.

Stereographic Projection.—In this projection the eye is supposed to be placed at the surface of the sphere, and to view the concave of the opposite hemisphere through the plane of that circle, in the pole of which the eye is placed.



If E be the eye, and A, G, C the hemisphere to be represented, A, B, C, D will be the plane of projection; and the position on this plane of any point of the spherical surface will be indicated by a line drawn from that point through the plane to the eye. Thus the points K, L, M, N on the sphere will be transferred to the plane at *k*, *l*, *m*, *n*.

The advantages offered by this method of projection have brought it more into use than the methods before mentioned. It is especially calculated for maps of the world, as usually made in two hemispheres, from the circumstance of the representation being less distorted, and also on account of the meridians and parallels intersecting each other at right angles, as they do on the globe. Its construction also is less difficult than others, since all the great circles of the sphere are either circles or strait lines in the projection. The meridian of 20° W. is the one usually selected by English geographers for the plane of projection in these maps of the world, because this meridian passes very nearly between the eastern and western continents, which therefore occupy their respective hemispheres.

Globular Projection.—This projection which is a modification of the Stereographic, was invented by the astronomer De Lahire, who supposed the eye to be placed at a distance from the sphere equal to the sine of 45°; that is, if the diameter of the sphere be equal to 200, the distance of the eye from the nearest point of the circumference would be $70\frac{7}{10}$. Some further modification was subsequently deemed desirable, in order that the meridians might intersect the equator at equal distances. This condition is very nearly fulfilled when the distance of the eye is 59½, the diameter being 200 as before.

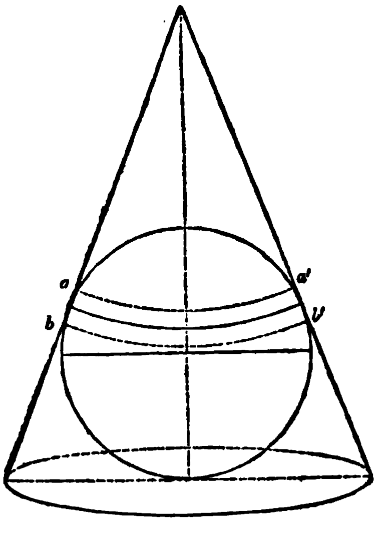
This projection is also much used in maps of the world, but to simplify their construction, the meridians and parallels are projected into circular instead of elliptical arcs, the deviation from the strict law of the projection being too slight to affect the practical utility of the map.

Of Projection by Development.

The developments to be mentioned are two—the *Conical* and *Cylindrical.*

Conical Projection.—In this projection the sphere is supposed to be circumscribed by a cone, which touches the sphere at the circle intended to represent the middle parallel of the map. If the points on the sphere be now projected on the cone by lines drawn from the centre, it is clear that in a zone extending but a short distance on each side the middle parallel, as the zone *a a′ b b′*, the points on the cone would very nearly coincide in position with the corresponding ones on the sphere. All the delineations having been thus made, the cone is then conceived to be unrolled, or developed on a plane surface.

Should the map be made to extend much above or below the middle parallel, the distant parts will be very much distorted. To remedy the defects of this projection, various modifications have been suggested, among which those of Flamsteed are generally held in the highest estimation. [Conic Projection.]



Cylindrical Projection.—From what has been said of the cone, it will be easily understood that a cylinder may be applied to the sphere in a similar manner, and that a zone of very limited extent in latitude may, without very material error, be developed on a cylinder. The peculiarity of this method is, that the meridians, as well as the latitude circles, are projected in parallel strait lines; a condition of the map which makes it very applicable to nautical purposes, and on which (partly) is founded the very ingenious method called *Mercator's Projection*, which is now so universally adopted in our charts, and to which, in conclusion, we will briefly allude.

Mercator's Projection.—The line on which a ship sails, when directing her course obliquely to the meridian, is on the globe a spiral, since it cuts all the meridians through which it passes at equal angles. This circumstance, combined with others, rendered a map constructed on the principles of the spherical projections very inadequate to the wants of the navigator. Mercator considered, very justly, that mariners do not employ maps to know the true figures of countries, so much as to determine the course they shall steer, and the bearing and distance of those points or places which lie near their track; and this projection is the result of his efforts to secure to the seaman these desirable ends. The merit of this most useful method is thought by many to be more justly due to Wright; for although Mercator published his first chart in 1556, he omitted to declare the principles on which he proceeded, and his degrees of latitude did not preserve a just proportion in their increase towards the poles. Wright, in 1599, corrected these errors, and explained the principles of his improved construction, in which the degrees of latitude on the chart were made to increase towards the poles, in the same ratio as they decrease on the globe; by which means the course which a ship steers by the mariner's compass becomes on the chart a strait line; the various regions of the map, however distorted, preserve their true relative bearing, and the distances between them can be accurately measured.

MAPLE. [Acer.]

MARACAIBO. [Venezuela.]

MARAGHA. [Persia.]

MARANHAO (Province). [Brazil.]

MARANHAO, or S. LUIZ DO MARANHAÕ, is a town on the northern coast of Brazil, in 2° 30′ 40″ S. lat. and 43° 50′ W. long. It lies on the north-western peninsula of an island, called Ilha do Maranhao. This island, which is nearly twenty miles long, extends along the shores of the continent, from which it is separated by a shallow channel, called Rio do Mosquito. This channel is, on an average, only 100 yards wide, and terminates in two large bays, the Bahia de S. Jozé on the east, and the Bahia de S. Marcos on the west. The island is generally low and swampy, and almost entirely covered with wood.

The town is built on the northern shores of a small peninsula, formed by two rivers, or rather small inlets of the sea, the Rio de S. Francisco on the north, and the Rio da Bacanga on the south. It is divided into two sections. The more ancient and populous part of the town, called Bairro da Praia Grande, extends along the shores on a broken surface. The streets are crooked, uneven, and badly paved; some of them are not paved at all. The houses have two or three floors, and are mostly built of sandstone. In this part of the town is a large square, surrounded by the palace of the governor, the college of the Jesuits, the townhall, and the prisons, which are substantial buildings. At the back of this section lies the other, called Bairro de N. Senhora da Conceição, which consists of small houses, many of which are surrounded by gardens and plantations. Each division has its own parochial church, besides which there are three other churches, two chapels, and four churches belonging to four convents. The town is defended by three small fortresses, now in a dilapidated state.

The harbour is good and safe, but the entrance is difficult, on account of a bank called Coroa do Meio, about thirty miles north of the town; on the east and west of which are deep channels leading into the harbour. The eastern, which is the most navigated, has on the east the great bank, or Coroa Grande, which extends between the northern shores of the island and the Ilha de S. Anna. The tide rises eighteen feet in the harbour, and twelve feet without it.

The mean annual temperature is 80° of Fahrenheit. The regular succession of the sea and land breezes, and the prevalence of northern winds, moderate the heat, and the climate of the town is considered healthy. The population, which amounts to about 30,000, contains a great number of unmixed descendants of Portuguese and negroes, the half-breeds being comparatively few in number.

The inhabitants are chiefly engaged in commerce: only the most common articles of domestic use are made in the town; the rest are imported from Europe. The trade is rapidly increasing. The number of vessels that annually entered the harbour amounted to more than 140 twenty years ago; they came from Lisbon, Oporto, Viana, Liverpool, and New York. The imports consist of wine, brandy, oil, flour, fruits, silk, cotton and linen goods, hardware and metals, and articles brought from the East Indies, as spices, &c., and drugs. The exports are cotton, which is by far the most considerable article, rice, tanned and raw hides, &c. Sugar and coffee are imported from Pernambuco, Bahia, and other parts of Brazil. (Spix and Martius, *Reise in Brasilien.*)

MARAÑON. [AMAZON.]

MARANS. [CHARENTE INFÉRIEURE.]

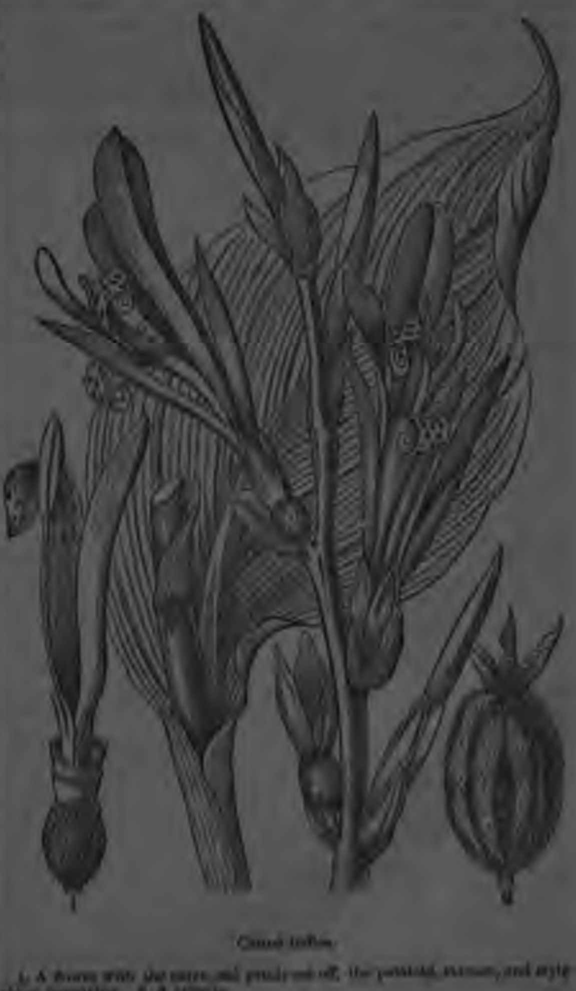
MARANTA ARUNDINA'CEA (Linn.). To this plant is referred the arrow-root of commerce, but it is also procured in large quantities from a variety of closely-allied, and even many distinct, plants. Thus the Surinam and Bermuda arrow-root is the produce of the M. arundinacea, while the Jamaica arrow-root is obtained from the M. indica (Tussac); which plant, along with several Curcumas, yields also the East Indian arrow-root. The West Indian arrow-root has mostly a pure white colour, the East Indian a yellow tinge.

The tubers, root-stocks, or offsets are grated or bruised, and repeatedly washed with water, which is passed through a fine hair-sieve, so long as it runs off with a milky appearance. It is allowed to subside, the supernatant water strained off, and the powder dried: 100 parts of the fresh plant yield 10 parts of arrow-root; but Benzon states 100 parts to yield 23 or 26 parts. According to the analysis of this chemist, it consists of volatile oil 0·07, starch 26, vegetable albumen 1·58, gummy extract 0·6, chloride of calcium, insoluble fibre 6, water 65·6. The volatile oil imparts a slight odour to the solution in warm water, which helps to distinguish genuine arrow-root from several of the articles substituted for it. Arrow-root has scarcely any taste, being bland and insipid; the powder, when pressed in the hand, emits a crackling noise, and retains the impression of the fingers, which common starch from wheat does not. Cassava (tapioca, from Jatropha or Janipha Manihot) also retains the impression of the fingers, but it has more odour and a somewhat acrid taste.

The meals of any cereal grain may easily be distinguished from arrow-root by the nitrogen which they contain, and the ammoniacal products which they yield by distillation. Potatoe-starch is however most frequently used to adulterate arrow-root, or as a substitute for it. Microscopic observation of the form and size of the grains will point out the difference, as first indicated by Raspail (*Annales des Sciences Nat.*, t. vi.), those of arrow-root being smaller; the different habitudes of the starch with re-agents will also do this. (See MM. Payen et Chevalier, *Traité de la Pomme de Terre*, p. 120; see also *Journal de Pharmacie*, Août, 1828.) Potatoe-starch is not soluble in cold water, which is the case with arrow-root. Dissolved in absolute alcohol, arrow-root separates into two distinct portions, which neither wheat nor potatoe-starch does. In equal proportions dissolved in warm water, arrow-root yields a thinner solution, with a more slimy aspect than wheat-starch.

Arrow-root dissolved in water, milk, or any other appropriate vehicle, constitutes, from its easy digestibility, a most excellent article of diet for delicate persons and young children. It may be given plain, or with wine or spices, according to circumstances. The valuable property just mentioned does not belong to either wheat or potatoe-starch. The latter, if prepared from potatoes in spring, is very liable to disturb the stomach; but less so if prepared in October or November. Potatoe-starch may be prepared at a very cheap rate, and kept for a long period unchanged, thus affording a protection against times of scarcity. (Sir John Sinclair, *On the Culture and Uses of Potatoes*, Edinb. 1828.)

MARANTA'CEÆ, a natural order of endogenous plants, which have either no stems or annual ones only, whose leaves have diverging veins, and whose flowers are constructed with an inferior ovary surmounted by a three-leaved calyculus; very irregular flowers, white, red, or yellow; and a single stamen, whose anther has but one lobe.



Canna indica.

1, A flower with the calyx and petals cut off, the petaloid, stamen, and style alone remaining. 2, A capsule.

With the exception of the genus Calathea, and of Canna, which is commonly cultivated, under the name of Indian shot, because of its beautiful flowers, the species included in this order are of small size, and by no means attractive, but the fleshy tubers of some of them abound in starchy matter, which renders them nutritious. Arrow-root of the finest quality is obtained from Maranta arundinacea, and a similar product is yielded by Canna edulis and others. The order is known from Zingiberaceæ by the anther having but one lobe, instead of two.

All the species are found wild in tropical countries only.

MARASMUS (emaciation) is a term often used by the older medical writers to designate those cases in which no particular cause for the atrophy of the body was discovered. It is now very rarely employed, since the condition which was thus named is known to be the result of some local disease, by which the complete nutrition of the body is prevented, or by which a quantity of its material is constantly abstracted; as disease of the mesenteric glands, pulmonary consumption, &c.

MARAT, JEAN PAUL, born near Neuchâtel in 1744, studied medicine at Paris. Although not deficient in intelligence and quickness, he wanted the application and perseverance requisite for the regular study of his profession, and he became an empiric. At the first symptoms of the Revolution in 1789, he showed himself a furious demagogue, addressing himself to the passions of the Paris populace, and preaching open insurrection and massacre. He was one of the members of the club of the Cordeliers, founded by Danton in 1790. He then became editor of a journal entitled 'L'Ami du Peuple,' which was hawked about the streets, and became a favourite with the lower orders. In this periodical he urged the poor to rise against the rich, the private soldiers against their officers, and the nation at large against the king. In 1792 he became a member of the first committee of public safety, and as such sent circulars all over France to recommend the massacre of the so-called aristocrats. He said in his paper that France would never be happy unless 270,000 heads were struck off by the guillotine; and he actually published long lists of individuals whom he denounced as proper objects of public vengeance. And yet this man was returned by the department of Paris to the national convention.

In the convention Marat was the declared enemy of the Girondins: he attacked them in April, 1793; but Robespierre, who was more cautious, checked him then: things were not yet ripe for their proscription. Marat was even impeached, and underwent a mock trial before his friends of the revolutionary tribunal, but was acquitted, and re-entered the convention in triumph. He saw the downfall of the Girondins, but did not long survive them. On the 13th of July, 1793, while taking a bath, a young woman from Normandy, named Charlotte Corday, was introduced to him, under the pretext of having some pressing information to communicate. She showed him a list of pretended aristocrats in her own district; and while Marat was reading it, she stabbed him to the heart, boasting that she had delivered France of a sanguinary monster. She was guillotined, and died with the greatest composure. [CORDAY D'ARMANS.]

Marat was proclaimed by the jacobins as a martyr of liberty, and his body was interred with great honour in the Pantheon, the former church of St. Généviève, from which it was removed after the end of the reign of terror. Marat has been called a madman, but there was method in his madness; he was one of those depraved men whom revolutionary convulsions throw up to the surface of society.

MA'RATHON, a small plain in the north-east part of Attica [ATTICA], about five miles in length and two in breadth (Dodwell), which is chiefly memorable for the victory which the Athenians under Miltiades gained over the Persians here, B.C. 490. [MILTIADES.] Marathon was the first place in Attica that was occupied by Pisistratus and his partisans, after he had been compelled to retire to Eretria in Eubœa. (Herod., i. 62.) The town of Marathon originally belonged to one of the four towns which formed the Tetrapolis, which consisted of Œnoe, Marathon, Probalinthus, and Tricorythus; but the name was afterwards applied to the whole district. (Steph. Byz., under τετράπολις τῆς Ἀττικῆς.) Marathon is about three miles from the sea, and is said by Plutarch to have derived its name from the hero Marathos. It is mentioned in the 'Odyssey' as a place of considerable importance (viii. 80); and it was near this place that the Athenians are said to have defeated Eurystheus, when they took up arms in defence of the Heraclidæ. Dodwell (*Classical Tour*, ii., p. 155) says that Marathon is 18 miles in a direct line from Athens to the village of Marathon; and that it is at least 22 miles by the shortest road to the commencement of the plain. According to Pausanias, it was half-way between Athens and Carystus in Eubœa (i. 32, § 3). Marathon belonged to the tribe of Leontis.

The plain of Marathon was watered by a small stream, called Asopus by Ptolemy, which forms marshes near the sea, in which, according to Pausanias (i. 32, § 6) a great many of the Persians perished. The Athenians who fell in the battle were buried in the plain; and also, but apart from the Athenians, the Platæans, Bœotians, and slaves. A large tumulus of earth still rises from the centre of the plain; and near the sea there are two others, much lower than the former. (Dodwell.) A little way above the plain, Pausanias mentions a natural cave, sacred to Pan (i. 30, § 6); which, according to Dodwell, is scarcely worth the trouble of visiting.

MARATTI, CARLO, the last painter of the Roman school, was born at Camurano, in the March of Ancona, in the year 1625. From his childhood he manifested a great fondness for drawing and painting. In his eleventh year he went to Rome, and became the favourite pupil of Andrea Sacchi, with whom he remained till he was 19 years of age. By studying the works of Raphael, the Caracci, and Guido Reni, he formed a style peculiar to himself, and acquired during his lifetime the reputation of being one of the first painters in Europe, though his talents were certainly not of the highest order. He was particularly celebrated for the lovely, modest, and yet dignified air of his Madonnas, which procured him the name of Carlo delle Madonne. He painted for Louis XIV. his celebrated picture of 'Daphne.' Pope Clement IX., whose portrait he painted, gave him a pension, and conferred on him an order of knighthood. The churches and palaces of Rome, which are filled with his works, are proofs of the esteem in which he was held. He was employed also in restoring the frescos of Raphael in the Vatican, and of Annibale Caracci in the Farnese palace. Fuseli says, 'The picture which gives the most advantageous opinion of his powers is "Bathsheba viewed by David," a work the charm of which it is easier to feel than to describe, which has no rival, and seems to preclude all hope of equal success in any future repetition of the same subject.' He also etched several beautiful plates. Of his pupils, the best known are F. Joranis and Chiari. He likewise promoted the art of engraving, and the famous engraver Jacob Frey was his scholar. In private life he was highly esteemed for his modesty and obliging disposition. He died at Rome in 1713, at the age of 88.

MARAZION. [CORNWALL.]

MARBECK, JOHN, who, as composer of the solemn and now venerable notes set to the *Preces* and Responses, which are still in use, with some alterations, in all our cathedrals, is entitled to our notice, was organist of Windsor during the reigns of Henry VIII. and his successor. A zeal for religious reformation led him to join a society in furtherance of that object, among the members whereof were a priest, a singing-man of St. George's chapel, and a tradesman of the town. Their papers were seized, and in the hand-writing of Marbeck were found notes on the Bible, together with a Concordance, in English. He and his three colleagues were found guilty of heresy, condemned to the stake, and all were executed according to their sentence, except Marbeck, who, on account of his great musical talents, and being rather favoured by Gardiner, bishop of Winchester, was pardoned, and lived to witness the triumph of his principles, and to publish his work, which appeared under the title of 'The Boke of Common Praier, noted;' the colophon being, 'Imprinted by Richard Grafton, printer to the kinges majestie, 1550, cum privilegio ad imprimendum solum.' In the same year appeared also his Concordance; and in 1574, 'The Lives of Holy Saints, Prophets, Patriarchs, and others;' and subsequently his other books connected with religious history and controversy. It is stated by Sir John Hawkins, highly to the honour of Marbeck, that, 'under the greatest of all temptations, he behaved (after his trial) with the utmost integrity and uprightness, refusing to make any discovery to the hurt of others.'

MARBLE. A strict definition of this term is perhaps impracticable, unless, with Da Costa, we limit it to the calcareous rocks, 'of very lively colours, and of a constitution so fine that they will readily take a good polish.' In a vague sense other ornamental stones, as granite and porphyry, may be ranked among marbles, but the catalogue of the typical or calcareous marbles is long enough without these somewhat inconvenient additions. A limestone which will admit of being worked easily and equally in all directions is properly called 'freestone,' as the Bath or Ketton freestone; a rock of similar chemical composition, generally capable of being worked equally in all directions, and also of taking a good polish, deserves the title of marble; when it is granular and of a white colour, it may be useful in statuary.

Da Costa, in his 'Natural History of Fossils,' gives a large catalogue of marbles, disposed in a methodical order, which we shall follow in the following brief notices of this extensive subject.

Division I. Marbles of one plain colour.

Section 1. Black marbles. Most of these contain bitumen, and are fetid when bruised.

Examples. The Namur marble, the marble of Ashford in Derbyshire, Dent in Yorkshire, near Crickhowell, Tenby, Kilkenny, &c. The marble, antiently called Marmor Luculleum, and now Nero Antico.

Section 2. White marbles.

Examples. The marble of Paros, in which the Laocoon and Antinous are executed; the Carrara marble, of finer grain, much used in modern sculpture; the Skye marble, noticed by Dr. MacCulloch; that of Inverary, Assynt, Blair Athol, &c.

Section 3. Ash and grey marbles.

Examples. A beautiful marble, of compact oolitic texture, at Orelton, near the Clee Hills in Shropshire, deserves mention.

Section 4. Brown and red marbles.

Examples. The Rosso Antico; a rival to which, at least in colour, has been found on the estate of the duke of Devonshire, near Buxton. The mottled brown marble of Beetham Fell, near Milnthorp, is of good quality.

Section 5. Yellow marbles.

Example. The Giallo Antico. Siena marble, also dug at Mafra, near Lisbon. That used in antient Rome is said to be from Numidia.

Section 6. Blue marbles.

Example near St. Pons in Languedoc.

Section 7. Green marbles.

Example. The Marmor Lacedæmonicum of Pliny. It is dug near Verona.

Division II. Marbles of two colours.

Section 1. Black marbles variegated with other colours.

Example. Near Ashburton in Devonshire, Torbay in the same county, Bianco e Nero Antico, the African Breccia of the antients, Giallo e Nero Antico.

Section 2. White marbles variegated with other colours.

Example. Marble imported from Italy. Marbles of this general character occur in Siberia, at Plymouth, at Killarney, in Sweden, &c.

Section 3. Ash and grey marbles variegated with other colours. These are very numerous, and occur in various parts of Europe.

Section 4. Brown and red marbles variegated with other colours.

Section 5. Yellow marbles variegated with other colours.

Section 6. Green marbles variegated with other colours.

Examples. Egyptian marbles—the Marmor Tiberium and Augustum of Pliny; some Verde Antico, as that dug near Susa in Piedmont, the beautiful marble of Anglesey (called Mona marble), the marble of Kolmerden in Sweden.

Division III. Marbles variegated with many colours.

Example. Some of the Plymouth marble, the beautiful Brocatello or Brocade marble of Italy and Spain.

Marbles containing shells, corals, and other extraneous bodies.

In this division of marbles the British Islands are rich. Some of the Plymouth, Ashburton, and other Devonian limestones are extremely beautiful, from the abundance of fine corals exquisitely preserved in them; the crinoidal marbles of Flintshire, Derbyshire, and Garsdale in Yorkshire, are elegant examples of the carboniferous limestone; the shell marbles of Rance (Northamptonshire), Buckingham, Whichwood Forest, Stamford, Yeovil, may be noticed from the oolitic rocks; that of Petworth and Purbeck, from the Wealden strata, has been extensively used by the architects of the middle ages. In general the working of the English marbles is costly, and their use limited.

MARBLEHEAD. [MASSACHUSETTS.]

MARBURG, the capital of the province of Upper Hesse, in the electorate of Hesse-Cassel, is situated in 50° 50′ N. lat. and 8° 47′ E. long. It is built on the banks of the Lahn, which divides the town from the suburb of Weidenhausen. The town is situated on the side of a hill, and the streets are very steep. On the top of the eminence overlooking the town there is a large castle, which was formerly well fortified and was the residence of the landgrave. The town is partly surrounded by a wall, in which there are five gates. Marburg has a university, which was founded in 1527, by the landgrave Philip the Generous. This university has very considerable revenues, and all the usual appendages of the German universities, with a library of 100,000 volumes, an anatomical theatre, a lying-in hospital, a chemical laboratory, a veterinary school, a botanical garden, a philological seminary, cabinets of mineralogy, &c. The number of students, which in 1818 was only 220, was 359 in 1828, 422 in 1833, and at present is about 450. The town has one Calvinist, one Roman Catholic, a French Protestant, and two Lutheran churches, one hospital, two infirmaries, an orphan asylum, a school of industry, &c. The church of St. Elizabeth contains the fine monument of St. Elizabeth, which was however much damaged under the Westphalian government. Marburg being the seat of the provincial government, of the criminal tribunal, a board of trade, a commission of police, and a Lutheran superintendant, the inhabitants, 7520 in number, derive their chief support from the presence of these and from the university. The place has some manufactories of woollen, linen, cotton, hats, tobacco, and tobacco-pipes.

MARCA D'ANCO'NA, an old denomination of a geographical division of the Papal State, whose limits correspond in great measure to those of antient Picenum, and which is now subdivided into the three administrative delegazioni or provinces of Ancona, Fermo ed Ascoli, and Macerata e Camerino. This fine region extends from the frontiers of Abruzzo to the boundaries of the former duchy of Urbino, now the province of Pesaro e Urbino, and from the Apennines to the Adriatic, along which sea it occupies a line of coast more than sixty miles in length. It has been called La Marca, 'the March,' since the time of the Carlovingian emperors and kings of Italy, from being governed by marchiones, or marquises, in the same manner as the Marca Trevigiana, or province of Treviso, in the county of the Veneti. [TREVISO.] March ('mark,' in German) meant originally a frontier district, but the term was afterwards applied rather capriciously, and the number of marquisates was multiplied in various parts of the revived Western empire. In the time of the Longobards the county, afterwards called Marca, was called Pentapolis, from its five principal towns, Ancona, Fanume, Pisaurum, Auximum (now Osimo), and Humana or Numana. The name of Marchia Anconæ is found in a diploma of the emperor Frederic I., of 1162. His son Henry VI. united it to the duchy of Ravenna. Innocent III. conquered the March, and placed it under the allegiance of the Roman see. During the troubles of the middle ages it was divided among several petty princes or tyrants, Varano of Camerino, Sforza, and others. Cesare Borgia subdued the country by force and treachery, and it became from that time annexed to the papal territories. It was then generally called Marca d'Ancona, from its principal town; but the south-east part of it was also sometimes called Marca di Fermo, and the two together were often designated, in the plural number, 'Le Marche.'

The Picentes, or antient inhabitants of Picenum, are said to have been a colony of the Sabines. Their country extended along the Adriatic, from the Æsis to the Truentum, which are also the limits of the modern Marca; but the Prætutii, who lived south of the Truentum as far as the river Matrinus (now Piomba), and formed a separate community, are included by Pliny and other antient geographers within the boundaries of the Picenum. The Æsis separated the Picentes from the country of the Senones; but some antient writers have considered the Picenum to extend as far as Ariminum. Asculum, Firmum, Pollentia, Ricina (believed to be Macerata), Treia, and Tollentinum, were towns of the Picentes. The Picentes made alliance with Rome, B.C. 299. During the war of Pyrrhus they joined the Samnites, Lucanians, and others against Rome, were defeated, sued for peace and obtained it, and a Roman colony was sent to Ariminum on that occasion. (Livy, *Epitome XV.*) Picenum then became a Roman province, and was administered by a proconsul.

The Picentes were foremost in the league of the Italian nations in the Social war: they killed the proconsul Servilius, and defeated Cn. Pompeius Strabo, but were afterwards defeated by him. [Ascoli.] They however obtained the civitas, like the other Italian people.

The actual delegazione of Ancona, bounded on the east and north-east by the Adriatic, on the north-west and west by the province of Pesaro e Urbino, and on the south by Macerata e Camerino, contains 155,000 inhabitants, distributed among six towns and thirty-four 'terre,' having communal councils. The principal towns are, 1, Ancona; 2, Jesi (the antient Asium), with 14,000 inhabitants; 3, Osimo, with 5000 inhabitants. (Calindri, *Saggio Statistico.*) The account of the other two provinces is given under Fermo ed Ascoli and Macerata e Camerino.

(Compagnoni, *Reggia Picena;* Colucci, *Antichità Picene,* 31 vols. 4to., Fermo, 1786-97.)

MARCELLIN, ST. [Isere.]

MARCELLI'NUS. [Ammianus Marcellinus.]

MARCELLI'NUS was bishop of Rome in the reign of the emperor Diocletian. He has been represented by some as having, through fear during the persecution raised under that emperor, offered incense to the heathen deities, but this is contested by others. He died A.D. 304.

MARCELLO, BENEDETTO, a patrician of Venice, son of Agostino Marcello, a senator, was born in 1686. His elder brother, Alessandro, who was much distinguished for his knowledge in natural philosophy and mathematics, as well as for his musical acquirements, had weekly music-parties at his house, to which probably the early predilection of Benedetto may be attributed. Among the masters to whom the care of his education was assigned are mentioned Gasparini and Lotti, under whom he studied composition, but we do not find that he produced anything particularly worthy of notice till 1716, in which year a serenata from his pen was performed at Vienna, when the birth of the first son of the emperor Charles VI. was there celebrated with much ceremony and splendour.

His great work, and that to which is to be ascribed the celebrity of his name throughout Europe—for as a Venetian noble he would have been known only in a small district, and but for a brief period—was published in 8 vols. folio, in the years 1724 and 1726, under the title of *Estro Poetico-armonico, Parafrasi sopra i 50 primi Salmi, Poesia di G. A. Giustiniani, musica de B. Marcello, patrizi Veneti.* The learned M. Suard, whose reputation as a musical critic once stood high, seems to approve the rather strong term with which this title commences; for, says he, nothing equals the enthusiasm that reigns in all these compositions; it transfers to music the energy of Oriental thought, and converts the composer at once into a Pindar and a Michael Angelo. Whatever may have been the degree of enthusiasm possessed by Marcello—and doubtless it was great—there is certainly too much of it in this opinion. Graceful and appropriate melody, supported by harmony of the purest kind, is his true characteristic. He occasionally, though not often, is grand, but this grandeur springs out of simple sources, and does not count learned combinations and complicated parts among its elements. In his style is to be traced sound musical knowledge, guided by good sense and polished by good taste. He is always elegant, never gorgeous, and as to the sublimity implied in the remark of the French critic, we have never discovered any signs of it in the works of the noble Venetian, much as we admire them for other valuable qualities.

Mr. Avison, in his well known *Essay on Musical Expression,* carries his admiration of Marcello's Psalms to great lengths, and leaves us to infer that he considers them at least on a level with the works of the Italian's great contemporary, Handel. Time has shown the extravagance of this opinion, and assigned to the Venetian composer his true rank, which undoubtedly is high, but far from being of the loftiest kind. Avison however evinced the sincerity of his admiration by issuing proposals for publishing an edition of the *Salmi* set to English words; but the execution of this design devolved on Mr. Garth, organist of Durham, who very skilfully adapted to the music our own prose translation of the Psalms, and published the work (which is now to be found in most musical libraries) in eight handsome folio volumes.

Marcello composed many other works besides his Psalms, but few, if any of them, have survived. He did not confine his attention to music, but was an active magistrate, and during many years one of the Council of Forty. He died in 1739.

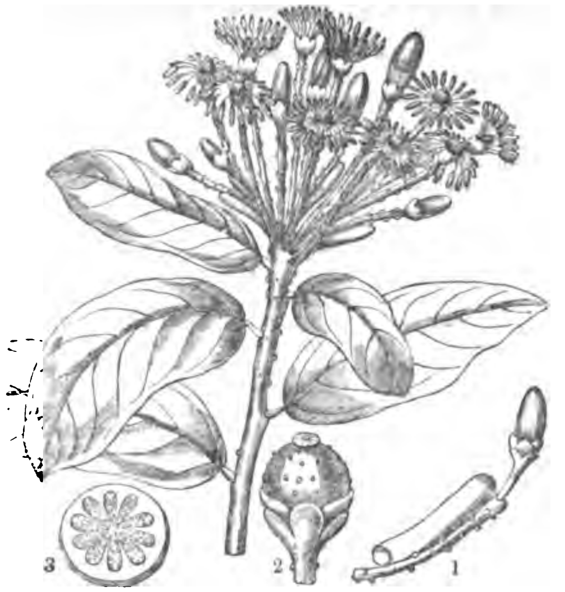
MARCELLUS, MARCUS CLAUDIUS, born of a Roman consular family, after passing through the offices of ædile and quæstor, was made consul B.C. 224. The Transpadane Gauls having declared war against Rome, Marcellus marched against them, defeated them near Acerræ on the Addua, killed their king Viridomarus, and carried off his arms, the 'spolia opima,' which were exhibited in his triumph. At the beginning of the second Punic war, Marcellus was sent to Sicily as prætor to administer the Roman part of the island, and had also the task of keeping the Syracusans firm to their alliance with Rome. After the battle of Cannæ he was recalled to Italy, to oppose Hannibal. He took the command of the relics of the Roman forces in Apulia, kept Hannibal in check, and defended Nola. In the year 214 B.C., being again consul, he took Casilinum by surprise. He was next sent to Sicily, where Syracuse had declared against Rome. [Hieronymus.] After a siege of nearly three years, the town was taken in the year 212 B.C., and Marcellus returned to Rome with the rich spoils. Archimedes lost his life on the occasion of this taking of Syracuse. [Archimedes.] Marcellus did not obtain the triumph, but only the ovation, as the war in Sicily was not entirely terminated. In the year 210 he was again chosen consul, and had the direction of the war against Hannibal in Apulia, when he took the town of Salapia, and fought several partial engagements with the Carthaginians without any definite result. In the following year he continued in command of the army, and fought a battle against Hannibal near Canusium, in which the Romans were defeated and ran away. On the following day Marcellus renewed the fight and defeated the Carthaginians, upon which Hannibal withdrew to the mountains of the Bruttii. In the next year, B.C. 208, Marcellus was elected consul, for the fifth time, with T. Quintus Crispinus. He continued to carry on the war against Hannibal, when, being encamped near Venusia, he rashly ventured out, fell into an ambuscade of advanced posts, and was killed. Hannibal caused his body to be buried with honours. (Livy, xxvii. 2, 14, 29.) He was one of the most distinguished Roman commanders during the second Punic war, and had the honourable reputation of a disinterested man.

MARCELLUS, EMPI'RICUS, was born at Bordeaux, and was *magister officiorum* in the reign of Theodosius the Great. The only work of his which has come down to us is entitled 'De Medicamentis empiricis, physicis et rationalibus,' published at Basle, 1537, Venice, 1547; and with the 'Medici Principes,' Paris, 1567. Though Marcellus does not appear to have belonged to the medical profession, he gives us much curious information respecting the manner in which medicine was studied at that time in Gaul.

MARCELLUS I. succeeded Marcellinus as bishop of Rome, but we know little of him, except that he is said to have been strict in enforcing the discipline of the church. He died A.D. 310.

MARCELLUS II. was elected after the death of Pope Julius III. in 1555, but died in less than a month after his election. He was succeeded by Paul IV.

MARCGRAA'VIACEÆ, a natural order of Polypetalous exogens, having an imbricated calyx, numerous hypogynous stamens, and a superior ovary with a discoid stigma and many polyspermous cells. They are all inhabitants of the tropical parts of America, and are usually scrambling shrubs, which are sometimes true parasites. The order is of no known use, and of but little interest, except in a systematical point of view; unless for the sake of its very curious bracts, which vary in form in different species, but which are usually more or less pitcher-shaped.



Marcgraavia umbellata.

1, a pitcher-shaped inverted bract adhering to the peduncle of an unexpanded flower; 2, a ripe fruit seated in the persistent imbricated calyx; 3, a transverse section of the same.

MARCH, the third month of the year according to modern computation, containing thirty-one days. The Roman year originally began with March [JANUARY], and was in fact so considered in England before the alteration of the style, the legal year commencing on the 25th of March. Our Anglo-Saxon ancestors called it most commonly *Hlyd monath*, loud or stormy month; and sometimes *Hræd* or *Rhæd monath*, which some interpret Rheda's, others *Rhede* or *Rethe*, the rugged or rough month. The name of the month is said to be derived from that of Mars, the god of war.

Before 1564 the computation of the French year began from Easter, so that occasionally the same year might comprehend two months of March, *Mars avant*, and *Mars après*. If Easter occurred in March itself, the month began in one year and ended in another. The change of computation from the first of January to Easter, in that country, was directed by an edict of Charles IX.

There is an old proverb, mentioned by various writers, which represents March as borrowing certain days from April. These are called, by the rustics in many parts both of England and Scotland, the *Borrowed Days*. They are particularly noticed in the poem called 'The Complaynt of Scotland :'

'March said to Aperill,
I see three hogs upon a hill;
But lend your three first days to me,
And I'll be bound to gar them die.
The first it shall be wind and weet,
The next it shall be snaw and sleet,
The third it shall be sic a freeze,
Sall gar the birds stick to the trees.
But when the borrowed days were gane,
The three silly hogs came hirplin hame.'

Dr. Jamieson, in his 'Etymological Dictionary,' says, 'These days being generally stormy, our forefathers have endeavoured to account for this circumstance by pretending that March *borrowed* them from April, that he might extend his power so much longer. . . . Those,' he adds, 'who are much addicted to superstition, will neither borrow nor lend on any of these days. If any one would propose to borrow of them, they would consider it as an evidence that the person wished to employ the article borrowed for the purposes of witchcraft against the lenders.'

Ray, in his Collection, has a different proverb relating to this month, viz. that 'A bushel of March dust is worth a king's ransom;' thereby expressing the importance of dry or dusty weather at this particular season of the year, in an agricultural point of view.

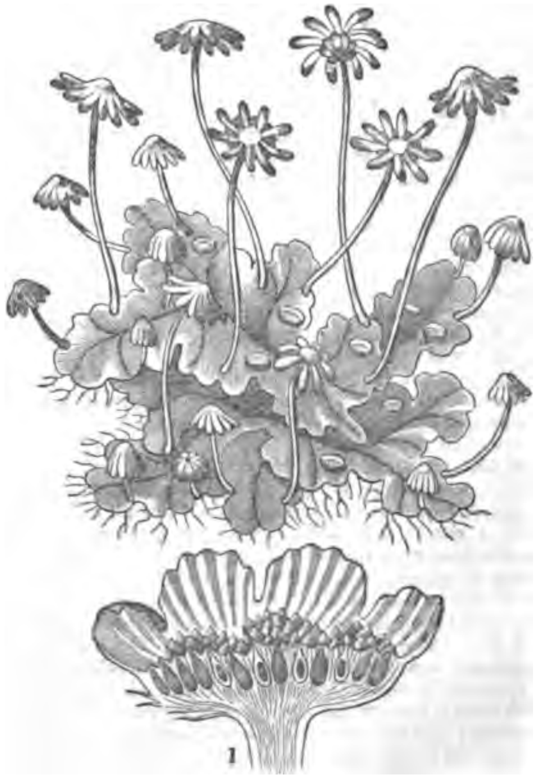
(Brady's *Clavis Calendaria*, 8vo., Lond., 1812, vol. i., p. 63; Furetière, *Dictionnaire Universel*; Brand's *Popular Antiquities*, 4to. edit., vol. i., pp. 86, 460.)

MARCH, in music, is, properly speaking, an air in duple time, played by martial instruments—*i.e.* by inflatile and pulsatile instruments—to mark the steps of the infantry, as well as to amuse and cheer troops of all kinds. It however has long since gained admission wherever music is heard, and consequently is written for every kind of musical instrument. Hence some of the most striking compositions by the greatest masters; as, for instance, the marches in Handel's oratorios; the religious marches (*Marches religieuses*) in Gluck's *Alceste* and Mozart's *Zauberflöte*; the two funeral marches (*Marcie funebri*) of Beethoven, &c.

The true March is always written in common time, or in what is called a compound of that measure, and begins on a broken part of the bar, with an odd crotchet or a quaver. It is slow for grand or parade occasions, quick for ordinary marching. We are told by Rousseau, that Marshal Saxe used the march also for the purpose of accelerating or retarding the pace of his troops in battle. In his days there was more form, more ceremony used; something like etiquette was kept up in fighting: we doubt whether the movements of the battalions in the fields of Austerlitz and Waterloo were performed to musical movements, or even to the simple beat of drums.

MARCHANTIA'CEÆ, a small natural order of Acrogens or Cryptogamic plants, forming part of the old group called Hepaticæ. They are plants of a low organization, in most instances having no distinction of leaves and stem, but a thin, leafy, lobed thallus in their room, in which respect they resemble lichens, but are furnished with breathing pores and an approach to spiral vessels in the form of elaters, which latter circumstances elevate them to the level of Lycopodiaceæ and Marsileaceæ.

Marchantiaceæ differ from Jungermanniaceæ, with which they were formerly combined under the old name of Hepaticæ, in not having a distinct stem, and in their fruit not being four-valved. Marchantia itself, a common plant under the north side of old walls and hedges, upon damp ground, forms deep green patches with a lobed lichenoid thallus, and has reproductive organs of two kinds arranged separately below mushroom-shaped heads; one of them appears to be male and the other female. None of the species are of any known use.



Marchantia polymorpha.

1, A vertical section of an involucrum, with the young capsules imbedded in the receptacle.

Endlicher separates the order into four, with the following distinctive characters:—

1. RICCIACEÆ. Frondose. Involucre none. Capsules bursting irregularly. Elaters none. Aquatics.

2. ANTHOCEROTEÆ. Frondose or leafy. Involucre none. Capsules 1-2-valved, with a central columella. Elaters.

3. Targioniaceæ. Frondose. Involucre heterogeneous. Capsules opening by teeth. Elaters.

4. Marchantiaceæ. Frondose. Both involucre and involucel. Capsules various, opening irregularly by teeth. Elaters. Flowers capitate.

MARCHE, LA, one of the provinces or military governments into which France was divided before the Revolution. It was bounded on the north by Berri, on the east by Auvergne, on the south by Limousin, and on the west by Poitou and a small portion of Angoumois. Its name, which denotes a frontier district, was derived from its situation on the border of Limousin (of which province it was formerly accounted a subdivision, being sometimes called La Marche du Limousin) toward Poitou and Berri. It was subdivided into La Haute Marche (Upper Marche), on the east side, of which Gueret (population 3100 town, 3921 whole commune) was the capital, and Aubusson (pop. 4354 town, 4847 whole commune), Bourganeuf (pop. 2110 town, 2849 whole commune), and Felletin (pop. 2816 town, 3228 whole commune), chief towns; and La Basse Marche (Lower Marche) on the west side, of which Bellac (pop. 3025 town, 3607 whole commune) was the capital, and Le Dorat (pop. 1805 town, 2237 whole commune) and Confolens (pop. 2215 town, 2687 whole commune), chief towns. La Haute Marche now constitutes the department of Creuse; La Basse Marche is included in the departments of Haute Vienne, Indre, and Charente.

This district was included in the territory of the Lemovices, a Celtic nation, who also occupied Limousin. In Roman Gaul it was comprehended in the province of Aquitania Prima, and afterwards was successively occupied by the Visigoths and Franks, under the latter of whom it made part of the duchy and kingdom of Aquitaine. In the tenth century it formed a county under Boson I., who was also count of Perigord. The county of Marche continued in the possession of the descendants of Boson until the beginning of the fourteenth century, when it was seized by Philippe IV. le Bel. It was subsequently given by Philippe V. le Long, as an apanage, to his brother Charles, who, upon coming to the crown, exchanged the county of Marche with Louis I., duke of Bourbon, for the county of Clermont. Upon the death of Louis, duke of Bourbon, the county of Marche came to his second son, Jacques or James of Bourbon, who was appointed by the king Jean II. constable of France. Jacques struggled against the English under the Black Prince, but with so little success that he resigned to the king his sword, the ensign of the constable's office. He was taken prisoner at Poictiers, A.D. 1356, and was killed A.D. 1361, with his son Pierre, fighting against the disbanded mercenaries, called the Tard-venus, near Lyon. [Lyon.] The county of Marche passed subsequently to the counts of Pardeac, a branch of the family of Armagnac, and from them to the dukes of Bourbon; and upon the confiscation of the territories of Charles, duke of Bourbon, by Francis I., it came to the crown, A.D. 1523, with which it was finally united.

The name of La Marche or Les Marches was formerly given to the frontier of Basse (Lower) Normandie, towards Maine and Perche. The towns of Argentun and Séez were included in this district.

MARCHES, THE. *Mark*, Anglo-Saxon meanc, is a word common to almost all the languages of Teutonic origin, in sense scarcely varying from the word as at present used, a *mark*. But from denoting a *mark* in general, it came to denote in a specific and peculiar sense those important *marks* by which the boundaries of wide domains were indicated, and in this sense it is found in Anglo-Saxon writings. Hence the word *the marches*, that is, the country lying near and about the *marks* which indicated the limits of two kingdoms, dukedoms, or other extensive jurisdictions.

The word is used in Germany, and upon it is founded one of their titles of honour, the *markgraf* (*margrave*), or lord of the marches; and our own *marquis* is of the same origin, though it does not appear that the few persons who in early times (there was no English marquis before the reign of Richard II.) bore this title had any particular connection with the marches.

Great part of England being bounded by the sea, there could be but little march-land. But on the side toward Wales, and in the north where England abuts upon Scotland, there was march-land; and when we speak of the marches, the land near the borders of the two countries is what is meant.

Wales being conquered by King Edward I., we hear little in history of the marches of Wales. But the term continued in use long after the conquest of that country. The great family so celebrated in the early history of England, whose hereditary name was De Mortuo Mari ('of the Dead Sea'), contracted and Gallicized into Mortimer, and whose chief residence was at Wigmore Castle in Herefordshire, had the chief management of the affairs of the Welsh marches, and was known by the title of Earl of March. King Edward IV., their lineal descendant and heir-general, was called Earl of March while his father was the Duke of York.

But Scotland remaining a distinct sovereignty for several centuries after the subjugation of Wales, the marches towards that country are frequently mentioned in history, and especially as being the scene of those predatory excursions in which the people of both countries frequently engaged, or of conflicts arising out of national jealousies and disputed rights. The maintenance of authority in those regions, lawless, or constantly liable to become so, was an object of great importance; and for this purpose the marches towards Scotland were divided into two portions, the western and the middle marches, each of which had courts peculiar to itself, and a kind of president or governor, who was called the warden.

MARCIA'NUS, born in Thrace, of obscure parents, towards the end of the fourth century, entered the army, rose gradually by his merit to high rank, and was made a senator by Theodosius II. When Theodosius died (A.D. 450) his sister Pulcheria, then fifty-two years old, offered her hand to Marcianus, who was near sixty, because she thought him capable of bearing the crown with dignity and advantage to the state. Marcianus married her, and was proclaimed emperor. His reign, which lasted little more than six years, was peaceful, and his administration was equitable and firm. He refused to pay to Attila the tribute to which Theodosius had submitted. In the year 455 Marcianus acknowledged Avitus as emperor of the West. Marcianus died in 457; his wife Pulcheria had died before him. He was succeeded by Leo I.

MARCHIENNES. [Nord.]

MARCIONITES, a religious sect of the second and third centuries of our æra, so called from their teacher Marcion, a native of Sinope and a priest, who adopted the old Oriental belief of two independent, eternal, co-existing principles, one evil and the other good. He endeavoured to apply this doctrine to Christianity, asserting that our souls are emanations of the good principle, but our bodies and the whole visible world are the creation of the evil genius, who strives to chain down our spiritual nature by corporeal fetters, so as to make the soul forget its pure and noble origin. He further maintained that the law of Moses, with its threats and promises of things terrestrial, was a contrivance of the evil principle in order to bind men still more to the earth; but that the good principle, in order to dissipate these delusions, sent Jesus Christ, a pure emanation of itself, giving him a corporeal appearance and semblance of bodily form, in order to remind men of their intellectual nature, and that they cannot expect to find happiness until they are reunited to the principle of good from which they are derived. Marcion and his disciples condemned all pleasures which are not spiritual; they taught that it was necessary to combat every impulse that attaches us to the visible world; they condemned marriage, and some of them even regretted the necessity of eating of the fruits of the earth, which they believed to have been created by the evil principle. The Marcionites spread far in the East, and especially in Persia. The chief opponent of Marcion was Tertullianus, who wrote a book to refute his doctrines.

(Tertullianus *Adversus Marcionem;* Pluquet, *Dictionnaire des Hérésies.*)

MARDIN, a town of Northern Mesopotamia, built on a steep hill which forms part of the chain that divides the basin of the Upper Tigris, or country of Diarbekr, from the plains of Sinjar, which are watered by the affluents of the Euphrates. Mardin is a considerable though poor town, and is said to contain 20,000 inhabitants, two-thirds of whom are Moslems, and the rest Christians, with some Jews. The Christians are divided between Syrians of the Greek Church, Nestorians, and Armenians. The Syrians, who are the most numerous, have two churches in the town and two convents in the neighbourhood. They read their church service in the Syriac language, which few of the congregation understand, the vulgar tongue being the Arabic. Their patriarch showed to Mr. Buckingham a handsome copy of the Gospels in Syriac, written on parchment, richly illuminated, and bearing the date of 1156.

Mardin has eight mosques, several bazaars, and some public baths. The castle, which is built on the summit of the hill above the town, is strong by its situation. The town of Mardin is nearly half-way between Diarbekr and Mosul, and on the road from Constantinople to Bagdad.

(Niebuhr; Buckingham.)

MAREMME, the name given in Italy to the unwholesome lowlands which extend along the coast of the Mediterranean. The name is especially applied to the lowlands of Tuscany and of the Papal State, which are the most extensive. The Maremme may be divided into basins. The first basin begins north of Lucca, and extends along the sea-coast as far as Leghorn, south of which town the ridge of Montenero projects as far as the sea-coast. This basin extends inland from ten to twelve miles to the hills east of Pisa; it also includes the lowest part of the course both of the Serchio and the Arno, and is called Maremma Pisana. The next basin is that of the Cecina, a river which enters the sea about eighteen miles south of Leghorn. This basin, which is called the Maremma of Volterra, is of small extent, for the hills again approach close to the sea a few miles south of the mouth of the Cecina. The third basin begins at Piombino, and extends as far as Monte Argentaro, a distance of about 60 miles in a direct line. It stretches from 10 to 20 miles inland, and includes the lower course of the rivers Cornia, Bruna, Ombrone, and Albegna, and the lakes or marshes of Castiglione and Orbetello. This large tract is called Maremma Senese, because it forms part of the province of Siena. It is also called the Maremma of Grosseto, from the town of that name which is situated in the midst of it. A description of these tracts, which constitute the Tuscan Maremma, is given under PISA and SIENA (Provinces).

The Roman Maremma, which is a continuation of that of Siena (for there is no interruption of hills near the coast between one state and the other), begins at the river Pescia, which marks the boundary of the two countries, and extends as far as Terracina on the frontiers of Naples. The whole of this tract, of more than 120 miles in length, is low and unhealthy; but its depth inland is very unequal, owing to various offsets of the lower Apennines, and also to detached ridges which approach the sea without coming close to it, and which partly enclose the lowlands. The Roman Maremma may therefore be divided into three basins. 1. That of the lake of Bolsena, including the banks of that lake and the course of its outlet, the river Marta, as well as the rivers Fiora, Arone, and Mignone. The mountains of Santa Fiora, on the borders of Tuscany, bound this basin on the north-west; and Mount Cimino, which is of volcanic formation, on the south-east, divides it from the basin of the Tiber. The lower steps of the ridge of Cimino approach the sea at La Tolfa, near Civitavecchia. This basin, which is generally called the Maremma of Corneto, includes the districts of Corneto, Montalto, Canino, Castro, and Civitavecchia. A description of it is given under PAPAL STATES.

The second basin, that of the lower Tiber, extends from Civitavecchia to Anzo. The volcanic ridge of the Alban Mount divides it on the south-east from the basin of the Pomptine Marshes. A description of both, with some account of the various phenomena of the soil and atmosphere, is given under CAMPAGNA DI ROMA. The Maremme are of two kinds; some are marshy, and others dry, but both are unwholesome, especially in summer.

The name of Maremma is not commonly used in the kingdom of Naples to designate the unhealthy lowlands of that country, which are also extensive, but the synonymous word Paduli, a corruption of paludi, is used instead.

The Tuscan government has of late years effected great improvements in its Maremma; the marshes have been drained, the lakes embanked, the ground has been brought into tillage, and colonies established. The government has published an interesting account of the works executed for these objects, with an atlas, fol., Florence, 1838.

MARENGO. [ALESSANDRIA; BONAPARTE.]

MARENNES. [CHARENTE INFÉRIEURE.]

MARENZIO, LUCA, certainly the most voluminous, and, in the opinion of many, the best of all the composers of madrigals, was born at Coccaglia in Brescia, about the middle of the sixteenth century. His parents were poor, but his fine voice recommended him to the protection of the principal ecclesiastic of the place, who had him instructed in music by Giovanni Contini, the author, we are told, of many sacred compositions. His first appointment was as *maestro di Capella* to the cardinal Luigi d'Este, and at Rome, says Adami, he was beloved and caressed by many great personages, and among the number by the king of Poland, on whose invitation he paid a visit to the dominions of that monarch. Peacham, in his 'Compleat Gentleman,' tells us that he was 'in displeasure with the pope, for over-much familiarity with a kinswoman of his holiness,' which was the cause of his quitting Italy for a time. He states other particulars relative to him, which are extraordinary at least, and not now worth investigating. Marenzio returned however to the papal city, and was admitted into the pope's chapel, but in what capacity does not appear: Peacham says as organist; Dr. Burney denies this, assigning as the reason of his disbelief, that in the papal chapel there is no organ. The *former*, who certainly was acquainted with Marenzio, describes him as a 'little black man;' and mentions the first, second, and third parts of his *Thyrsis*, as 'songs the Muses themselves might not have been ashamed to compose.' He died at Rome in 1599.

In relation to his style of composition the Italians described him as *il più dolce cigno* (the sweetest swan), and the praise thus poetically expressed was perfectly just. Indeed as respects tenderness of air and gracefulness of harmony he has had few rivals. In vigour of imagination he has superiors, among whom our own best English madrigalists may be named without incurring the charge of national partiality. Even Peacham, his eulogist, mentions several English composers who, he says, 'are inferior to none in the world (how much soever the Italian attributes to himselfe) for depth of skill and richnesse of conceipt.' As he was one of the earliest composers of eminence, his works have been open to all, and he has been more or less imitated by many writers of vocal music in parts. Handel and Purcell, as Dr. Burney remarks, did not disdain to become his debtor.

MAREOTIS. [ALEXANDRIA; EGYPT.]

MARGARET, daughter of Waldemar III., king of Denmark, married in 1363 Haquin, king of Norway, on the death of Waldemar. In 1375 Margaret's son Olaus, then a minor, succeeded to the crown of Denmark under the guardianship of his mother. His father Haquin dying, Margaret was acknowledged queen of Norway. Olaus died in 1387, and the Danes also acknowledged Margaret as their queen. She turned her arms against Albert, king of Sweden, who was not popular with his subjects, defeated him, and made him prisoner, and was then acknowledged queen of Sweden. After seven years' confinement, she released Albert, on condition of his formally renouncing the crown of Sweden. In 1396 the estates of the three kingdoms assembled at Calmar, where it was agreed that in future they should all be ruled by one and the same sovereign. This act was called the 'Calmar Union.' On this occasion Margaret designated her nephew Erick as her successor. She died in November, 1412, being 59 years of age.

Margaret had many great qualities; but her political conduct, especially in her transactions with Sweden, was not free from duplicity and violence. To the Danes however she proved a good queen. She loved pomp and splendor, was brave and resolute, and had rather the qualities of the stronger sex than those of her own. [ERICK XIII. of Sweden.]

MARGARET OF ANJOU. [HENRY VI.]

MARGARET OF RICHMOND. [HENRY VII.]

MARGARIC ACID, a fatty acid, so called by Chevreul, who discovered it, from 'margarites' (μαργαρίτης, *a pearl*, on account of its peculiar lustre. It is prepared from soap made with olive-oil and potash; this is to be perfectly dried, and then macerated for twenty-four hours in twice its weight of cold alcohol. The *oleate of potash*, which the soap also contains, is dissolved by the alcohol, while the margarate of potash remains unacted upon; this is to be well washed with cold alcohol, and then dissolved in 200 parts of boiling alcohol: on cooling, the margarate of potash crystallizes; and as it contains a little oleate, it is to be crystallized a second time: it is then to be decomposed, and the margaric acid precipitated by the addition of hydrochloric acid.

The properties of this acid are, that on cooling, after fusion, it crystallizes in pearly needles; it is insoluble in water, and hence its precipitation from its compounds and solution by the stronger acids. It has an acid reaction; and its salts, except those of the alkalis, are very sparingly soluble in water. Its saline compounds are termed *margarates*.

According to the analysis of Berzelius, it consists of—

Thirty-three equivalents of hydrogen		33 or	12·59
Thirty-five equivalents of carbon	.	210	78·38
Three equivalents of oxygen	. .	24	9·03
Equivalent		267	100·

The crystals contain 3·4 per cent. of water, which can be separated only by converting the acid into a margarate by combining it with a base.

Margarate of Potash is obtained as above stated by the action of alcohol on soap made of olive-oil and potash; it separates from its solution in boiling alcohol in brilliant scales: with ten times its weight of water, at about 158°, it forms a limpid solution, which begins to become turbid at about 140°, and at 60° it becomes gelatinous; a larger quantity of water partially decomposes it, and converts it into bimargarate: at 55°, when exposed to a moist atmosphere, it absorbs its weight of water without becoming liquid; 100 parts of alcohol are capable of holding 1·21 part in solution when cold, 10 parts when hot. Æther, when heated, separates a little margaric acid.

Bimargarate of Potash is soluble in hot alcohol, 100 parts (of sp. gr. 0·834) dissolving 31·17 parts at 148° Fahr., of which however only 1·13 part remains dissolved at 68°.

Margarates of Soda strongly resemble those of potash: the neutral salt dissolves in 10 times its weight of water at 172°, and the solution becomes gelatinous at 148°, and contains a little acidulous salt.

Margarates of Lead.—Of these there are three, a sub-, neutral-, and super-salt. The neutral is produced by double decomposition: it contains combined water, and fuses at about 170°: boiling alcohol of sp. gr. ·823 dissolves about $\frac{3}{100}$ of its weight; it is less soluble in boiling æther.

When fat is boiled with the alkalis, as in preparing soap, it appears that the elements of the fat, without either yielding anything to or absorbing anything from the air, are converted into one or more fatty acids and glycerin; to these changes the elements of the water however contribute; the new acids, combining with the alkalis, form soap, which collect on the surface of the fluid, while the glycerin remains in solution.

MARGARIN, a peculiar fatty matter contained in vegetable oils, and also in animal fats, as mutton-suet and hog's-lard: when these have been treated with æther, for the purpose of obtaining stearin from them, the æthereal liquors, by spontaneous evaporation, deposit a portion of the solid matter which they contain, and this is to be collected on a linen cloth, strongly pressed, and then exposed for a long time to the heat of a salt-water bath. This substance is very soluble in cold æther, which distinguishes it from stearin. It appears probable however that by boiling in alkaline solutions it is converted into stearic acid; but additional experiments are required to determine its nature with precision.

MARGARI'TA, Dr. Leach's name for the 'Concha margaritifera or Matrix Perlarum, *Mytilus margaritiferus* of Linnæus, *Meleagrina margaritifera* of Lamarck. [AVICULA.]

MARGARITA'CEA, M. de Blainville's name for his third family of *Lamellibranchiata*. This family comprises the genera *Vulsella*, *Malleus*, *Perna*, *Crenatula*, *Inoceramus*, *Catellus*, *Pulvinites*, *Gervillia*, and *Avicula*. [AVICULA; MALLEACEA.]

MARGARITIC ACID. When eight parts of castor oil are saponified by two parts of hydrate of potash dissolved in four parts of water, by heating them together for some minutes the oil is rendered completely soluble in water. MM. Bussy and Lecanu have discovered in this soap three different fatty acids, the *margaritic*, *ricinic*, and *elaiodic*, which are obtained by saturating the base with hydrochloric acid. These acids form a reddish yellow oil, which at a temperature of about 60° Fahr. deposits a small quantity of solid matter, which is the margaritic acid. This is to be pressed between folds of blotting-paper, then dissolved in boiling alcohol, from which it separates on cooling in pearly scales which redden litmus paper. This acid fuses at about 270° Fahr.; its saline compounds, which however are but little known, are called *margaritates*. According to Bussy and Lecanu hydrated margaritic acid is composed of—Hydrogen, 10·91; Carbon, 70·50; Oxygen, 18·59.

MA'RGARON, a solid white fatty matter which crystallizes in pearly scales, and is obtained by distilling margaric acid with excess of lime. It fuses at about 170° Fahr., is volatile, soluble in fifty times its weight of hot alcohol, and five times its weight of boiling æther. Exposed to the action of heat in close vessels it distils almost unchanged; it burns in the air with a brilliant flame. Nitric acid acts but slightly upon it; sulphuric acid chars it, and sulphurous acid is given out. The alkalis do not act upon margaron.

This substance is composed of—Hydrogen, 13·42; Carbon, 83·37; Oxygen, 3·21.

MARGATE, a seaport town on the coast of Kent, in the parish of St. John, hundred of Ringslaw, and Isle of Thanet, 40 miles east-north-east from Maidstone, and 65 east from London (direct distances). Its name is probably derived from Meregate, signifying an opening or gate into the sea. Hasted, in his 'History of Kent,' published in 1799, says, 'The town of Margate was till of late years a poor inconsiderable fishing-town, built for the most part in the valley adjoining the harbour, the houses of which were in general mean and low; one dirty narrow lane called King Street having been the principal street of it.' At present the principal streets of Margate are regularly constructed and well paved, and lighted with gas; and many of the houses and public buildings, including an esplanade, squares, &c., are of a superior description. The spring-water is excellent and the supply abundant. The shore is well adapted to sea-bathing, and to this circumstance, added to the generally acknowledged salubrity of the air, and the facility of communication with the metropolis by means of steam-vessels, must be attributed the rapid increase in the population of the parish of St. John, which in 1831 amounted to 10,339. A handsome new church has been built at Margate within these few years. There is an hospital, called Draper's Hospital, founded in 1709 by Michael Yoakley, a member of the Society of Friends, for the housing and maintenance of decayed housekeepers. The sea-bathing infirmary at West-Brook, near Margate, was established by the benevolent Dr. Lettsom in the year 1792, assisted by committees which had been formed both in London and Margate. The object of the founders was to enable poor people to participate in the advantages of sea-bathing. The building consists of a centre building and two wings, and contains wards for the reception of nearly one hundred patients. The national school affords gratuitous instruction to about 400 children of both sexes.

The present stone pier was erected under the superintendence of Messrs. Rennie and Jessop, at an expense exceeding 100,000*l*. It is 900 feet long, and at its extremity is the lighthouse, built from a design of Mr. Edmunds. The erection of this pier has added greatly to the utility of the harbour, which is much exposed to winds from the north-east.

Margate is within the jurisdiction of Dover, one of the Cinque-ports. In the year 1787 the inhabitants thought their town of too much importance to be longer subjected to this jurisdiction, and accordingly applied to the crown for a charter of incorporation; but upon the case being heard before the attorney-general, the opposition of Dover was so strong that their petition was refused, and since then the application has not been renewed. [CINQUE PORTS.]

(Hasted's *Hist. of Kent*; *Beauties of England and Wales*; *Population Returns*.)

MARGINELLA. [VOLUTIDÆ.]

MARGINO'PORA, a genus of MILLEPORÆA.

MARIA THERE'SA, archduchess of Austria, queen of Hungary and Bohemia, and empress of Germany, born in 1717, was the eldest daughter of Charles VI. of Austria, emperor of Germany. [CHARLES VI.] In 1724 Charles by his will, known by the name of the Pragmatic Sanction, regulated the order of succession in the family of Austria, declaring that, in default of male issue, his eldest daughter should be heiress of all the Austrian dominions, and her children after her. The Pragmatic Sanction was guaranteed by the diet of the empire, and by all the German princes individually, and also by several other powers of Europe, but not by the Bourbons.

In 1736 Maria Theresa married Francis of Lorraine, who, by the peace of Vienna of the preceding year, had been recognised as the future grand-duke of Tuscany, after the death of Gian Gastone, the last offspring of the house of

Medici. Gian Gastone died in July, 1737, and Tuscany became subject to Francis, who, in January, 1739, repaired to Florence with his consort. Upon the death of Charles VI., in 1740, the king of Prussia, the elector of Bavaria, the elector of Saxony, France, Spain, and the king of Sardinia, agreed to dismember the Austrian monarchy, to parts of which each of these powers laid claim. Maria Theresa however, with a spirit and decision remarkable for her age, lost no time in repairing to Vienna and taking possession of Austria, Bohemia, and her other German states; she then proceeded to Presburg, took the oaths to the constitution of Hungary, and was solemnly proclaimed queen of that kingdom in 1741. Frederic of Prussia offered the young queen his friendship on the condition of her surrendering Silesia to him, but she resolutely refused, and Frederic invaded that province. The elector of Bavaria on his part, assisted by French auxiliaries, invaded Austria and Bohemia, and pushed his troops to the gates of Vienna. Maria Theresa being obliged to quit her capital, repaired to Presburg. Convoking the Hungarian diet, she appeared in the midst of that assembly with her infant son Joseph in her arms. She told the magnates, prelates, and deputies, that 'being assailed by enemies on every side, forsaken by her friends, and finding even her own relatives hostile to her, she had no hopes except in their loyalty, and that she had come to place under their protection the daughter and the son of their kings.' This heart-stirring appeal was answered by a burst of chivalric enthusiasm. The Hungarian nobles, drawing their swords, unanimously cried out, 'Moriamur pro Rege nostro Maria Theresa,' and the whole military force of Hungary was soon in arms to defend their queen. Her troops under General Kevenhüller and Prince Charles of Lorraine, her brother-in-law, fought gallantly, and drove the French and Bavarians out of the hereditary states. In the meantime Charles Albert, elector of Bavaria, was elected emperor of Germany, by the diet assembled at Frankfort, by the name of Charles VII.

Frederic of Prussia soon made peace with Maria Theresa, who was obliged to surrender Silesia to him. She also made not only a peace but a treaty of alliance with the king of Sardinia against the French and Spaniards, who were kept in check on the side of Italy. In 1743 the French were entirely driven out of Bohemia. In 1744 Frederic again declared war against Maria Theresa, and invaded Bohemia; but the elector of Saxony, who had made his peace with her, sent the queen reinforcements which obliged the Prussians to evacuate the country. In 1745 Charles VII. died, and Francis, Maria Theresa's husband, was elected emperor. In 1746 the Austrian and Piedmontese troops obtained great advantages in Italy; they gained the battle of Piacenza against the French and Spaniards, and occupied Genoa, which however they afterwards lost through a popular insurrection. In 1747 the war continued to rage in Italy and Flanders, with various success. In 1748 the peace of Aix-la-Chapelle terminated the war called 'the war of the Austrian succession,' and Maria Theresa was left in peaceful possession of all her hereditary dominions, except Silesia, which the king of Prussia kept.

In 1756 began the Seven Years' War, between France, Austria, and Russia on one side, and Frederic of Prussia on the other. [FREDERIC II.] It ended in 1763, leaving both Austria and Prussia with the same boundaries as before. In 1765 Maria Theresa lost her husband, for whom she continued to wear mourning till her death, and her son Joseph was elected emperor. [JOSEPH II.] She however retained in her hands the administration of her dominions, and devoted all her cares to promote their prosperity and to the improvement of the people under her sway.

The only act of Maria Theresa's political life with which she can be reproached is her participation in the first partition of Poland. The plan however did not originate with her, and she for some time refused to accede to the treaty of partition drawn up by Prussia and Russia in 1772, until she was plainly told that Russia and Prussia would effect the dismemberment of Poland without her consent, and that by refusing to accede to it she would only endanger her own dominions. Prince Kaunitz and her own son Joseph II. urged her to join the two other powers; she was told that Gallicia and other parts of Poland were antient dependencies of the crown of Hungary, and at last she gave her assent.

The improvements which Maria Theresa made in her dominions are many and important. In 1776 she abolished the torture in her hereditary states, and in the kingdoms of Hungary and Bohemia. In 1777 she abolished the rural and personal services which the peasants of Bohemia owed to their feudal superiors, and commuted them for a sum of money. Literary piracy was forbidden under severe penalties. Between the years 1774-8 she occupied herself with the establishment of a general system of popular education in her dominions. She divided the schools into three classes: 1, 'normal schools,' one in each province, to serve as a model for all the other schools in the province; 2, 'principal schools,' in the large towns; 3, 'communal schools,' in the small towns and villages. A director had the superintendence of the normal schools; those of the large towns were under the superintendence of a magistrate; and the communal schools under the parish priest and an assessor of the communal council. A central commission of studies was also appointed to superintend the whole, which received annual reports, and examined candidates for the masterships. Maria Theresa also suggested the addition of manual labour to intellectual instruction in the communal schools. She promised an extra remuneration to those teachers whose wives taught the girls sewing, knitting, spinning, &c. This plan answered extremely well, especially among the peasantry of Bohemia. Little girls thus taught were able to earn as much as half a florin a day. This was the beginning of that system of popular education which has since been extended through the Austrian monarchy.

Maria Theresa was a pious woman; she was a sincere Roman Catholic, but not a blind devotee of the court of Rome, and she knew how to discriminate between the temporal and spiritual jurisdictions. In her instructions to the Junta, or Board of Public Economy, dated June, 1768, she states the principle that 'everything which is not of divine institution is subject to the supreme legislative authority of the state.' Agreeably to this principle she made several important reforms in the temporalities of the clergy: she suppressed the pensions charged at Rome upon benefices; she forbade the alienation of landed property in favour of ecclesiastical bodies; she ordered all the property of the clergy to be registered; she placed the convents under the jurisdiction of the respective bishops, and in temporal matters under that of the civil magistrate. She put a check to the arbitrary power of the Inquisition, which still existed in her Italian dominions; she took out of its hands the censorship of books and gave it to a commission of civil magistrates appointed for the purpose. In Tuscany, which was administered by a council of regency in the name of her second son Leopold, she ordered that lay assessors should be joined to the inquisitors in all suits for heresy. She also took away the sbirri, or armed force, which was before under the orders of the inquisitors. The Inquisition of Lombardy and Tuscany was finally abolished under the reign of her sons Joseph and Leopold.

Maria Theresa possessed the strong affection of her Belgian subjects, and it required all the subsequent rashness of Joseph II. to detach them from their loyalty to Austria. The Belgian capitalists eagerly supplied the loans which the court of Vienna was obliged to contract during the Seven Years' War.

In Lombardy the administration of Maria Theresa and of her minister Count Firmian was a period of returning happiness for that fine country, after the vicissitudes of the preceding wars and the previous long misrule of the Spanish governors. The empress ordered a new censimento, or valuation of estates, for the purpose of an equitable assessment of the land-tax; she caused the bilancio camerale, or a regular budget of the public revenue and expenditure, to be made; she abolished the custom of farming the various branches of the indirect duties to the highest bidder, made regulations to protect the peasants against the oppression of their feudal superiors, and established representative communal councils to superintend the local expenditure; she began, in short, and effected to a considerable extent, that great legislative and administrative reform which was completed under her successor Joseph II. Firmian encouraged men of learning, and protected them against the cabals of their enemies. Pietro Verri was made counsellor and president of the financial board; Beccaria was appointed professor of political philosophy; Carli was made president of the council of commerce; and the advice and suggestions of these men were listened to, appreciated, and followed. The naviglio, or navigable canal of Paderno, which joins the Adda to the Martesana, was executed under Maria

Theresa. In 1749, soon after she obtained peaceful possession of Lombardy, the duchy of Milan contained 900,000 inhabitants; in 1770 the population had risen to 1,130,000.

'Lombardy,' says a liberal writer of our times, 'had never enjoyed so much happiness and tranquillity as under her reign; it is recorded to her praise that she wished to be informed of every act of the administration, that she gave free access to her presence to the humble and poor as well as to the noble and rich, that she listened benignantly to all, either granting their petitions, or, if she denied them, giving reasons for her refusal, without illusory promises or vague circumlocutions. She declared, just before her death, which happened at Vienna on the 29th November, 1780, that if anything reprehensible had been done in her name, it was certainly without her knowledge, as she had always wished the welfare of her subjects. During a forty years' reign she always showed a love of justice and truth, and she stated, as a principle of her conduct, that it is only the pleasure of alleviating distress and doing good to the people that can render the weight of a crown supportable to the wearer.' (Bossi, *Storia d'Italia*, b. vi., ch. 15.) Another merit of Maria Theresa is the propriety of her private character; her whole conduct was characterised by that decency and self-respect, united with much simplicity of manners, which is become a distinctive characteristic of the Austrian imperial family. Maria Theresa will ever rank high among illustrious women, and among those sovereigns who have been the benefactors of mankind. With her ended the house of Austria Habsburg, and at the same time began the present dynasty of Austria Lorraine.

Frederic II. appeared really affected when he heard of the death of Maria Theresa. Writing to D'Alembert, he said that 'although he had made war against her, he had never been her personal enemy; that he always respected her, and that she was an honour to her sex and the glory of her throne.'

MARIA'NA, JUAN, was born at Talavera in 1536. He early showed great talents, which were developed under the eminent teachers of the university of Alcalá, such as Father Cyprian of Huerga and others.

At the age of seventeen Mariana joined the Jesuits, who had already acquired a reputation which attracted to them the ablest students. He had to pass two probationary years at Simancas, under Saint Francis of Borja, the hereditary duke of Gandía, and favourite of Charles V., who had renounced the world to join the new order. After this probation Mariana returned to Alcalá to resume his studies. In 1568 he was appointed to a professorship by Laynez, the second general of his order, who framed the rules of the Jesuits, raised their aspirations, prepared them for the influence which they afterwards exercised, and opened their splendid college 'Il Gesu,' at Rome.

In this college Mariana, at the age of twenty-four, taught scholastic philosophy and divinity. Among his pupils was the young Jesuit (afterwards cardinal) Bellarmin. Mariana was sent in 1565 to open a course of divinity in Sicily, and thence to Paris two years after on the same mission, in which he was still more successful. Seven years of unremitting application in an uncongenial climate so greatly impaired Mariana's health, that he was permitted to retire to Toledo, near his birthplace. But his talents and moral worth were still put in requisition. He restored and edited the works of Saint Isidore, to which he added some valuable notes. When Leon de Castro questioned the orthodoxy of Arias Montano, for introducing Rabbinical readings and commentaries into the 'Plantina Regia,' or 'Philippina Polyglott,' a new edition of the 'Complutensis,' which Montano had undertaken at the command of Philip II., Mariana silenced the noisy polemic by his historical, ecclesiastical, and biblical lore, as well as by the fair and candid tone of his discussion.

In the mean time he proceeded during his leisure hours with the great work which he had long contemplated. He had observed that the sudden rise and ascendency of Spain excited a general interest and curiosity abroad, while its origin and causes were either unknown or misunderstood. The Spanish historians, though numerous, were at that time little read, and some of them were hardly known. His 'History of Spain' first appeared in twenty books, under the title 'Historiæ de rebus Hispaniæ,' fol., Toleti, 1592, libri xx. It was subsequently extended to thirty books, in which form it appeared in the complete edition of 1605, published at Mainz. This compact and lucid exhibition of an unbroken chronological narrative, from the origin of the Spanish nation to the death of Ferdinand the Catholic (a period of twenty-five centuries at least), embraces the history of all the Spanish kingdoms, which had hitherto been treated separately. A subject so extensive, expressed in classical Latin, met with universal favour and acceptance. A Spanish translation soon became necessary, and fortunately Mariana accomplished the task himself, and carried the work through four successive Spanish editions in his lifetime.

Mariana has been charged with credulity; but traditions held sacred in times past, although rejected in the present age—prodigies which formed part of history, and which Mariana could not dismiss with the disdainful smile of the ready presumption of modern criticism, are spots which will never obscure the brilliancy of his digressions on the most important events of the world, events which appear as great causes when so admirably interwoven with those peculiarity belonging to the history of Spain.

The manly feelings of the historian, his noble indignation against crimes, his bold exposure of the misdeeds of princes and their abettors, deserve still higher commendation. Yet he, as well as Ferreras and Masdeu more recently, has spared a gross instance of Queen Urraca's licentious conduct; but on the other hand, the defence of Queen Blanca's honour is highly creditable to Mariana. It is true also that Mariana did not always examine all the original authorities, as Ranke observes in the 'Kritik neuerer Geschichtschreiber;' but to institute an inquiry into every minor detail, to comprehend a wide field of inquiry, and yet to open new and to disdain all trodden paths, would have required the perusal of whole libraries, and a single life would not have been sufficient to complete the undertaking. And if others had been invited to join in the labour of the investigation, a motley compilation might have been the only result of so much research, which it is almost impossible ever to combine into one harmonious whole. Mariana's portraits of lords and favourites were found too original and faithful by the living; as in the case of the Condestable of Castile, Ferdandez Velasco, and his worthy secretary Pedro Mantaono. The secretary, after having been a panegyrist of the new historian, tried to serve his master by his attack on Mariana, entitled 'Advertencias á la Historia de Mariana.' He was discovered however, and roughly treated by Tamayo Vargas in 'La Defensa de Mariana.' Probably to this criticism may be traced many improvements in Mariana's second Spanish edition of his history, which appeared at Madrid, 1608. It is on this edition and the various readings selected from the editions of 1617 and 1623, that the edition of Valencia is based, which contains ample notes and illustrations, 9 vols. 8vo., 1783-96. This edition also closes, like the original, with the reign of Ferdinand the Catholic (1515-16). There has subsequently been published at Madrid—1, The continuation of Mariana, by Miñana, translated from the Latin, by Romero, fol., 1804; 2, A complete Mariana, continued down to the death of Charles III., 1788, by Sabau y Blanco, 20 vols. 4to., 1817-22; 3, Another by the same, brought down to the year 1808, 9 vols. 8vo., with portraits.

Mariana's little respect for potentates and great personages was denounced with greater asperity when his 'De Rege et Regis Institutione' appeared in 1599. By his attempt on the life of Henri IV., in 1594, Jean Chatelet, who had studied among the Jesuits, not only involved the whole body in the odium of his crime, but provoked a decree for their expulsion from France. Finally the assassination of Henri, in 1610, which was supposed to have been instigated by the Jesuits, excited such horror, that the parliament of Paris condemned the new tract of Mariana to the flames, and his treasonable doctrines, as they were called, continued during the whole of that age of loyalty and part of the following to furnish a common subject of animadversion and a chief ground of accusation against the Jesuits. The Jesuits have indeed occasionally supported the claims of the people against their rulers, but always with a view to the interests of their own body only. Mariana, on the contrary, discussed this subject on better and higher grounds. Mankind occupied his thoughts, and had a much stronger hold on his affections than the interests and plans of his order. By his defence of Arias Montano, already mentioned, he lost a chance of preferment, which however he was glad to exchange for learned leisure and the gratification of his love of historical research. Mariana published also, in 1599, his imperfect work, 'De Ponderibus et Mensuris,' a subject which his countrymen Lebrija or Nebrija, Diego Covarruvias, Pedro Ambrosio Morales, and Arias Montano, had treated before, and which Eisenschmidt, Freret, Paucton, &c., have pursued much further since.

The noble character and the profound erudition of Mariana are also displayed in his 'Tractatus Septem,' Cologne, 1609. The second of these treatises, 'De Editione Vulgatâ,' is an epitome of his report on the fierce controversy between Arias Montano and Leon de Castro. The fourth, 'De Mutatione Monetæ,' provoked the indignation of the duke of Lerma and his partners in the system of general peculation and frauds which Mariana exposed. He foretold the calamities which threatened the Spanish nation; and his words, which had been disregarded, were remembered when the opportunity was gone. As a reward for proclaiming such unwelcome truths, at the age of 73 he suffered a whole year of judicial trickery, humiliations, and confinement in the convent of St. Francis at Madrid. In searching his papers another exposure was found, entitled 'Del Gobierno de la Compañía,' or on the defects of his order, in which he also pointed out the means of correcting them. Copies of this MS. had multiplied so alarmingly, that, the year after the author's death, the general of the Jesuits, Vitelleschi, issued a circular, dated Rome, July 29, 1625, enjoining the collection of such papers in order to be burnt. Still that measure did not prevent its being printed at Bordeaux in 1625, and reprinted elsewhere in several languages. This curious circular was found in the archives of the Jesuits of Valencia at the time of their sudden expulsion from the Spanish dominions in 1767; a blow which helped to complete that downfal against which Mariana had most earnestly warned his brethren so long before.

After his persecution he made an epitome of the 'Bibliotheca' of Photius, translated some homilies, revised his 'History of Spain,' and published a supplement, or rather a summary, or concise annals of Spain from 1515 to 1612. At the age of eighty-three he published his 'Scholia' on the Old and New Testament, availing himself of the best Hebrew commentaries, and some valuable and very early MSS. which dated from the age of the antient Gothic dominion in Spain. This work secured for him a place among the best commentators in the 'Histoire critique du Vieux Testament' of the hypercritical Father Simon, who is usually unfavourable to Spaniards.

Bayle, in his 'Dictionary,' supposes Mariana to be also author of a work 'De Republicâ Christianâ,' but neither Alegambe nor Nicolas Antonio, both of them Spaniards, mentions it. Stevens, the English translator of Mariana's history, misstates some particulars of the author's life, and very unaptly compares him with Raleigh.

Mariana left MSS. of at least twice the extent of all his publications. He ended a long life, almost entirely devoted to the service of his own and future generations, on the 6th of February, 1624, in the eighty-seventh year of his age and the forty-ninth of his retirement to Toledo. On hearing of his death, the illustrious Francis Contreras, president of the council of Castile, said, 'To-day has the council lost its restraint.'

Besides the authorities quoted there may be added:—Mondejar, *Advertencias á Mariana*; *Juicio y Noticia de los Historiadores de España*; Andrade, *Vida de Mariana*; Acosta, *Vida de Mariana*; Andr. Schot., *Hispan. Illustrat.*; Baronius, *Annal. Ecclesiast.*; Bernard. Girald., *Pro Senatu Veneto*,' quoted in Colomesius, *Hispania Orientalis*; René Rapin, *Réflexions sur l'Histoire*.

MARIE ANTOINETTE, born at Vienna, in November, 1755, was the daughter of Francis of Lorraine, emperor of Germany, and of Maria Theresa of Austria. In May, 1770, she married Louis, the dauphin, grandson of Louis XV., who in 1774 became king of France, under the name of Louis XVI. She was handsome, lively, and thoughtless, but kind-hearted and with good intentions. She disliked the etiquette and reserve of the court, but she affected, rather too ostentatiously, a taste for privacy and domestic familiarity. Although her thoughtlessness afforded a pretence for slander, her private conduct has been generally allowed to have been guiltless. When the difficulties and dissensions which produced the Revolution began, Marie Antoinette was on the side that was for making resistance; but unable to impart energy to her husband, she only led him into inconsistencies. She did not disguise her aversion to those leaders who had begun the Revolution, and would never stoop to conciliate their favour. After the national assembly had assumed the supreme power, she refused the offers of Mirabeau to support the interests of the crown, and thus drove that able but unprincipled orator back into the ranks of the revolutionists. But her influence in the councils of Louis has been much exaggerated by her enemies. Louis, naturally disposed to concession, was by temper irresolute, and he allowed himself to be led away by the course of events, instead of striving to direct them. Marie Antoinette was one of the advisers of the attempted flight of the king, which proved unsuccessful, and only served to excite the public animosity against her and her husband. After that epoch there was no longer much opportunity for her to exercise any political influence; her husband had lost all power; besides which, a strong faction supported by the armed masses had determined to do away with the kingly office altogether. Marie Antoinette showed great courage during the various attacks made against the royal family; she appeared much more anxious about her husband and her children than about herself. She shared their captivity with resignation; her demeanour, under the most trying circumstances, never lost its dignity. Adversity imparted firmness to her mind, and she exhibited a moral strength which astonished while it irritated her bitterest enemies. After the death of her husband, she seemed forgotten for a time; but the terrorist faction having overthrown the Girondins, its leaders resolved to make away with the ex-queen, an act of cruelty the more odious as it was entirely useless. They brought her to trial before the convention. She was of course found guilty, and condemned to death. In the presence of her judges her fortitude never forsook her, and the burst of indignant maternal feeling with which she appealed to the mothers who might be there present, when an infamous and absurd charge was brought against her, overawed even her accusers.

On the 16th of October, 1793, Marie Antoinette was removed in a common cart from the prison of the Conciergerie to the place of execution. On her way she was reviled and abused by the ferocious mob in the most unfeeling manner; but she appeared heedless of their vociferations, and suffered death with firmness and composure. She was forty-two years of age, but her sufferings had given her a much older appearance. She left one son, who died in prison (Louis XVII.), and a daughter, who is the present duchess of Angoulême.

Medal of Marie Antoinette.

MARIE DE' ME'DICI, the daughter of Francis I., grand-duke of Tuscany, and of the archduchess Joan of Austria, was born at Florence in 1573, and was married in 1600 to Henri IV. of France. She was handsome, and Henri was for a time really attached to her; but she was violent, jealous, and obstinate, and seldom passed a week without quarrelling with her husband. The memoirs of Sully and others contain details of these domestic bickerings. But the best historical critics acquit her of any more serious misconduct, and especially of the odious insinuation thrown out by some writers, that she was privy to the murder of her husband. Henri at that time was just going to set off for the army, and he had signified his intention to leave her regent of the kingdom. Hérault only observes that she did not show sufficient grief for the death of her husband. Mary was weak rather than wicked; she had the aspirations of ambition without corresponding mental powers; and when she became regent, during her son's minority, she found herself incapable of bearing the weight of the administration. [Louis XIII.] She next quarrelled with her son, and made peace with him by means of Richelieu, whom she had introduced into the council; but she afterwards grew jealous of his great influence, and plotted against him. She was exiled, A.D. 1630; went to Belgium, England, and Germany; and at last died at Cologne, in 1642, in a state bordering upon destitution.

MARIE-GALANTE, an island in the Carribean Sea, about 15 miles south of Guadaloupe. It is of a circular form, and about 14 miles in diameter. This island was discovered by Columbus in 1493, and was first settled by the French in 1647. It has always been considered a dependency of Guadaloupe, and has uniformly followed the fate of that island when taken by any foreign power. [Guadaloupe.] The surface of Marie-Galante is of moderate elevation, and rises gradually towards the north; the western side is flat. The soil is productive, and yields abundantly the several West Indian products; but its exports and imports having always been included in the official statements with those of Guadaloupe, we have no record of the amount of its productions. The same course has been followed with regard to other statistical details, and we are therefore unacquainted with the amount of its population. Some authorities state it to be about 10,000. The only town, Basseterre, stands on the south-west point of the island, in 15° 52′ N. lat. and 61° 22′ W. long.

MARIE-AUX-MINES, SAINTE. [Rhin, Haut.]

MARIENBERG, a town in the kingdom of Saxony, in 50° 4′ N. lat. and 16° 45′ E. long., at an elevation of 2000 feet above the level of the sea. It has mines of silver, iron, tin, and cobalt, and produces arsenic and vitriol. The inhabitants, about 4000, besides working the mines, manufacture lace, linen, calico, &c. The silver mines were discovered at the beginning of the sixteenth century, and the town was founded in consequence in 1519 by Henry duke of Saxony. It is well built, with straight streets, a handsome market-place, a church, a gymnasium, an orphan asylum, and an institution for poor or disabled miners.

MARIENBURG, a town of West Prussia, in the government of Danzig, is situated in 54° 1′ N. lat. and 19° 2′ E. long., on the banks of the Nogat, over which there is a pontoon bridge 540 feet in length. It is chiefly celebrated as having been the seat of the Grand-master of the Teutonic Order from the year 1309 to 1466. The antient castle, and the lofty towers and parapets, which are the remains of the old fortifications, give it, when seen at a distance, a grand and striking appearance. The style of building is antient but irregular. Here and there are some more modern edifices, especially in the principal street, which however do not harmonise with the general character of the architecture. In front of the houses on both sides of the streets there is a connected line of porticos, the origin of which dates from the first building of the town in 1276 by the Teutonic knights. The remains of the palace of the Order are extremely grand, and his royal highness the crown-prince of Prussia has caused it to be repaired and partly restored to its antient splendour. The town is surrounded by a rampart, outside of which are two suburbs. There are extensive breweries and distilleries, and some manufactures of linen, woollens, leather, and cotton, but scarcely sufficient for the consumption of the town. The inhabitants carry on a considerable trade in the exportation of corn, timber, and fish, and likewise in the less important articles of quills and hogs' bristles. The population, 9000 in number, are chiefly Roman Catholics and partly Lutherans.

MARIENWERDER, one of the two governments into which West Prussia is now divided, lies between 52° 46′ and 54° 6′ N. lat., and 16° and 21° E. long., and is bounded on the north by the government of Danzig, on the east by that of Königsberg, on the south by Poland, on the south-west by Posen, on the west by Brandenburg, and on the north-west by Pomerania. Its area is 6880 square miles, and the population 460,000. The government is divided into 13 circles.

The circle of Marienwerder contains 343 square miles, with a population of 45,000.

Marienwerder, the capital, situated on the Liebe and the Little Nogat, two miles from the Vistula, over which there is a pontoon bridge 2700 feet in length, has 5500 inhabitants. It is a very neat town, with four suburbs, and has considerably increased during the present century. It is the seat of the provincial courts and the government offices. There are manufactories of woollens, hats, soap, and leather. [illegible] breweries and distilleries are very considerable.

MARIENZELL, or MARIAZELL, a small town in Upper Styria, the most celebrated place of pilgrimage in the Austrian dominions, is situated on a low hill in the middle of an extensive valley. It consists of only three streets, with 120 houses, of which nearly 50 are inns and taverns, and the population does not exceed 1000. The most considerable edifice is the church, built in the Gothic style, in which is the famous statue of the Virgin Mary, which was brought here 700 years ago. Princes and nobles rivalled each other during many centuries in bestowing the most costly gifts upon the church, and its treasury contained immense riches, which however have been greatly diminished in modern times by various accidents, especially by the great fire in 1827, when the whole town, except nine houses, was reduced to ashes. The roof and the steeple of the church were destroyed, but the treasury and the statue of the Virgin Mary were saved. It was however necessary to sell a great part of the treasures in order to repair the church, which is now more splendid than ever. The number of pilgrims that resort thither from all parts of the Austrian monarchy is estimated at 100,000 every summer. Under the reign of the emperor Joseph II., all processions of pilgrims, and particularly those to Marienzell, were prohibited, but were again permitted in 1796 by the emperor Francis. The procession, in 1819, consisted of about 12,000 pilgrims, who, being handsomely dressed in the costume of the several provinces from which they came, presented a striking and interesting appearance.

MARIESTAD. [Sweden.]

MARIKINA. [Midas.]

MARIMONDA. [Ateles, vol. ii., p. 547.]

MARINE INSURANCE. The general principle upon which insurances are made, whether of property against the chance of fire, of human life against the accidents or contingencies of mortality, or of ships and their cargoes against the multiplied risks to which they are exposed, is the same: viz. that of reducing to each individual in every case, his possibility of loss down to the average loss of a great number of individuals or cases. Marine insurances differ however from fire and life insurances in the mode of conducting the business, as well as in the diversified nature of the risks against which security is sought. The chief of these in time of peace include the chances of fire, of piracy, of barratry of the master or crew, *i.e.* the running away with the vessel by these parties, as well as the more ordinary mischances resulting from storms, sunken rocks, fogs, and the like. To these are superadded, in time of war, the chances of capture by an enemy, and all restraints of foreign princes or governments.

Until a recent period nearly all the marine insurances effected in London, which is the great emporium of such business, were made with individuals who became answerable for comparatively small portions of the sum insured, differing thus from other kinds of insurances where the whole risk was taken by a joint-stock association. Until 1824 it was not lawful for any two or more individuals, with the exceptions that will be mentioned, to combine together for taking upon themselves sea-risks, and all the business of this kind transacted in London was undertaken by a class of persons called underwriters, from the mode employed of binding themselves to the conditions of the contract by writing their names and the sums which they assured under the deed in which these conditions were set forth. The exceptions to the limitation of partnership, just mentioned, were made in favour of two chartered joint-stock companies, the Royal Exchange and the London Assurance companies. Endeavours were made at various times to alter the law in this respect, and were always successfully resisted on the part of the underwriters until 1824, but since that time it has been lawful for any number of persons to associate themselves together for undertaking marine insurances, and many joint-stock companies for that purpose have been formed and put in action with advantage to the public. Before the year 1824, several insurance clubs, which were in fact mutual insurance associations, existed and were considered legal. In those there was no payment made of premium, but each member of the club was periodically called upon to pay a proportion of the losses sustained by the members of the club generally, the rate of his contribution being made to depend upon the value of the property, in respect of which he might have sustained loss, that would have been made good to him. These clubs, which still exist, are usually confined to persons engaged in particular branches of trade, such as the coal-trade of the North of England, where the risks incurred by the different members are generally equal in degree, a condition which is necessary in order to render the association equitable.

The policy, or contract of insurance, must contain the name of the ship, when known, and of the master, with the nature of the voyage, and must describe also in good faith any circumstances which are out of the ordinary or understood course in similar risks or voyages, such as any contemplated deviation from the route usually followed. The business of effecting insurances is sometimes done by the merchants or owners of the ships or goods insured, but more frequently through the agency of insurance-brokers, whose remuneration comes from the underwriters or insurance-offices, as the case may be, and not from the assured, their employers. That remuneration consists in an allowance of 5 per cent. on the amount of the gross premium *in each case*, and in a further allowance of 12 per cent. upon the net amount of premiums paid by them to the underwriters or offices at the end of the year, after deducting all losses and averages recovered for the assured.

The policy of insurance, when underwritten by the assurer, bears a declaration of the amount of premium having been paid, but in practice that payment is not made until some months after the expiration of the current year in which the risks are taken, unless in the case of a total or partial loss, when all premiums outstanding upon the account of the merchant or broker, as the case may be, are allowed as a set-off against the amount of the loss. Where a broker is employed, the underwriters give credit to him, and not to his employers, for the amount of premiums, and they have recourse for the same only to the broker. As some compensation to the broker for the 12 per cent. allowance above mentioned, which he foregoes in the event of a loss, he makes a charge against the merchant by whom he is employed of ten shillings for every hundred pounds upon the amount recovered.

The rate of premium varies of course with the nature of the voyage, the period of the year, and the quality of the ship. As regards this latter point the underwriters and managers of insurance companies are enabled to judge with great accuracy by means of a register kept under the superintendence of a committee of merchants and underwriters, in which every necessary particular concerning every mercantile ship is inserted from the surveys of competent officers appointed for the purpose, who are paid certain fees for their trouble by the owners. This register is of as much importance to the shipowner as it is to the underwriter. If the quality of the vessel is seen to be good, the charge made for premium of insurance is less than where that quality is bad or doubtful; and in the event of loss it gives readier means for rebutting the charge of unseaworthiness than might otherwise be found, such a charge, when proved, being held in law to exonerate the underwriter from payment of the loss.

The losses for which underwriters are liable are either total or partial. In some cases it may happen that the claim upon an underwriter exceeds the amount of his subscription, as where a ship meets with damage, and after quitting a port where she has been repaired or refitted, is wrecked or otherwise lost. The claim in such cases would be not only for the amount expended in repairs, but also for the value of the ship or goods, when lost. Partial loss or damage is called an average loss, and averages again are divided into the two classes of general average and particular average. Under the first of these heads are included all losses of a part of the property voluntarily incurred for the preservation of the remainder. If a ship is thrown on her beam ends, and to right her the masts are cut away, this constitutes a general average, and the loss must be borne in shares proportionate to their value by the owners or insurers, as the case may be, of the ship and the cargo. So if a ship lying at anchor should be in danger of dragging her anchor, and so going on shore, and the cable should be cut, or if to lighten her in a storm part of her stores or cargo should be thrown overboard, this would constitute a general average, and must be met by the owners or insurers of the whole property as before described. Particular average arises when the ship or the cargo meets with damage from any of the chances against which insurance is provided, but which is not incurred voluntarily and to prevent a greater loss. In these cases the damage must be made good by the insurer of the ship or of the goods which are damaged, and not by a general contribution from all. Where this partial damage happens to the ship it is usual for the underwriters to reinstate the same, paying two-thirds only of the cost, it being considered that the owners of the vessel will benefit to the extent of the remaining one-third by receiving new articles in place of those in use which have been lost, or by the better state in which the vessel will be placed by the repair. Goods which are peculiarly liable to damage, either from their nature or from the manner in which they are packed, are not entitled to claim particular average except the ship be stranded, or except the damage shall exceed a certain per centage of the value. Corn, seed, flour, fish, salt, and fruit are not liable to particular average, whatever be the amount of damage, except the ship be stranded; and sugar, tobacco, hemp, flax, hides, and skins are warranted by the assured free of particular average, unless the damage should amount to five per cent. or more of their value, with the like exception as regards stranding.

It is not possible to give within reasonable limits more than a very general view of the law and practice connected with marine insurances, concerning which many volumes have been published.

Policies of insurance on sea risks are liable to stamp duties, which vary according to the nature of the voyage and the rate of the premium, viz. :—

On coasting risks where the premium does not exceed 20*s.* per cent. the stamp duty is 1*s.* 3*d.* per cent.; and where the premium exceeds that rate it is 2*s.* 6*d.* per cent. On foreign risks, where the premium is not higher than 15*s.* per cent., the duty is 1*s.* 3*d.* per cent.; when the premium is between 15*s.* and 30*s.* per cent. the duty is 2*s.* 6*d.* per cent.; and when the premium exceeds 30*s.*, the duty is 5*s.* per cent.

Vessels engaged in voyages of long duration, such as the South Sea whaling-ships, or vessels employed in a particular line where the risk is unvarying, are sometimes insured for a specific time. The stamp duty in such cases is 2*s.* 6*d.* per cent. for a period not exceeding three months, and 5*s.* per cent. between three months and twelve months, but no time risk for a longer period than twelve months can be covered by the same stamp, and a new policy must then be taken out.

MARINER'S COMPASS. [COMPASS, MARINER'S.]

MARINES, men embodied to serve as soldiers on board of ships of war in naval engagements, and on shore, in the event of a descent being made upon an enemy's coast. In the British service, they also assist occasionally in performing some of the operations connected with the working of the ship; they cannot however be sent aloft at the command of a naval officer.

Originally in this country, as well as in France, the national fleets were composed of merchants' ships, which were armed on occasion for war; and then there were no soldiers particularly destined for the naval service. The first troops of this kind in France were men skilled in the practice of the useful trades, who, when unemployed by the government, lived on shore on half-pay; receiving only the full pay when called upon to serve at sea. This regulation did not however long subsist; and, subsequently to the administration of Cardinal Richelieu, companies of marine soldiers have been constantly retained on full pay.

It is not precisely known at what period distinct corps were appointed, in Britain, to this branch of the public service. In 1684 mention is made of the duke of York's maritime regiment of foot; and in the reign of William III. several regiments were placed on the establishment of the navy, but these were subsequently disbanded. At that time the marine soldiers seem to have been retained as persons in training to become good seamen; and, in Burchet's 'Naval History,' quoted by Grose ('Mil. Antiq.,' vol. i.), it is said that they were discharged from the regiments and entered on the ship's books as foremast-men as soon as they became qualified to serve as such.

In the beginning of Queen Anne's reign (1702), six regiments of maritime soldiers were raised; and among the regulations concerning their service it is stated that they were to be quartered, when on shore, near the principal seaports. Whether at sea or on shore, they were to be paid at the same rate as the land forces, and the same deductions were to be made for clothing. At sea they were to be allowed provisions equal in every respect to the shares of the seamen, without suffering any diminution of pay on that account.

In 1749, the then existing regiments of marine soldiers, ten in number, were disbanded; and six years afterwards, on the recommendation of Lord Anson, there were raised 130 companies, consisting in all of above 5000 men, who were put under the immediate command of the lords of the admiralty, and whose head-quarters were appointed to be at Plymouth, Portsmouth, and Chatham. The corps of marines, as it was then called, has subsequently been considerably increased; in 1759 it numbered 18,000 men; and during the late war its strength amounted to about 20,000 men. An additional division was, by an order of council in 1805, established at Woolwich; and there are two companies of marine artillery, whose head-quarters are at Portsmouth.

The marines are now clothed and armed in the same manner as the infantry of the line, and, like all the other royal regiments, their scarlet uniform has blue facings. In an engagement at sea, they annoy the enemy by a fire of musketry from the tops and deck; and they repel with the bayonet any attempt to board the ship. The gallant *jollies*, as the marines are familiarly called, have often distinguished themselves when acting on shore; and their meritorious services at the taking of Belleisle (1761), in the battle of Bunker's Hill (1775), in the defence of Acre (1799), and very recently, under Lord John Hay, on the coast of Spain, have earned for themselves a lasting reputation.

The royal corps is commanded by a lieutenant and a major-general, who are naval officers holding, in addition to their rank as such, those military titles. There are also four colonels-commandant of divisions, besides four colonels and second commandants. No commissions in the corps are obtained by purchase; and the officers of marines rise in it by seniority, as high only however as the rank of colonels-commandant.

MARI'NO, SAN. [SAN MARINO.]

MARIOTTE, EDME. Little is known of his life. He was a Burgundian born, a priest by profession, and resided in the earlier part of his philosophical career at Dijon. He was afterwards prior of Saint Martin, near Beaune, and died May 12, 1684, having been one of the first members of the Academy of Sciences. See the éloge by Condorcet, vol. i., p. 74, of his collection.

Several of the writings of Mariotte were published by himself, and one or two more after his death. Those of the former class were several times reprinted, and the whole were finally collected under the title 'Œuvres de Mariotte,' in two volumes quarto, Leyden, 1717. Another edition (perhaps the same with a new title) was published at the Hague, in 1740. This collection contains treatises on percussion, on vegetation, on the nature of the air, on heat and cold, on the nature of colours, on hydraulics, on some phenomena connected with sight, on levelling, on the motion of the pendulum, on the congelation of water, and on the logic of the sciences.

Condorcet says of Mariotte, that 'he was the first Frenchman who carried with him into experimental philosophy a spirit of observation and doubt, and inspired others with that caution and timidity which are so necessary to those who interrogate nature and undertake to interpret her responses.' His writings, though more connected with mathematical deduction than those of Robert Boyle, somewhat resemble them in the miscellaneous character of the experiments with which they are crowded.

The principal results by which the name of Mariotte is known to a reader of modern works are the following:—

1. He was the discoverer of that law of elastic fluids which now goes by his name; that is, of the elastic force being exactly in the inverse proportion of the space which a given mass of fluid occupies. Subject to such alterations as difference of temperature may require, the formula derived from this law is now one of the fundamental parts of aerostatics.

2. He discovered that air, and air in a state of condensation, exists in liquids.

3. He found that the part of the retina in which it meets the optic nerve is not capable of conveying the impression of sight.

Among minor matters, we may mention the now common guinea and feather experiment, which he first made with the air-pump.

MARITIME LAW. [ADMIRALTY COURTS; SHIPPING.]

MARITZA, the modern name of the Hebrus, the principal river of Thrace. The basin of the Hebrus is enclosed between the chain of Hæmus, or the Balkan, on the north, and Mount Rhodope, the modern Despoto, on the south; the first divides it from the basin of the Danube, and the other from that of the Strymon. [AMPHIPOLIS.] The Hebrus rises at the foot of Mount Rhodope, in about 42° N. lat. and 24° E. long., and flows in an easterly direction for more than 100 miles, receiving numerous affluents from both chains of mountains: it passes by Tatar Bazardjik, Philippopolis, and Chirmenli (the antient Assus), where it diverges to the south-east until it reaches Adrianople, where it is joined by two large streams, the Toonja, or Tonzus, from the north, and the Arda, or Harpessus. After passing Adrianople the Hebrus turns to the south, receives the Erkeneh (the antient Agrianes), coming from the direction of Constantinople, flows by Demotica, and, after numerous windings, enters the gulf of Ænos by two mouths, opposite the island of Samothrace. The whole course of the Hebrus is above 300 miles. It is navigable for small craft as far as Adrianople, about one-third of its course.

MA'RIUS, CAIUS, was born of humble parents, at or in the neighbourhood of Arpinum, about B.C. 157. He served at the siege of Numantia, B.C. 134, under Scipio Africanus, together with Jugurtha, where he highly distinguished himself. He received great marks of honour from Scipio, who used frequently to invite him to his table; and when, one evening at supper, Scipio was asked, where they should find so great a general when he was gone, he is said to have replied, placing his hand upon the shoulder of Marius, 'Here perhaps.'

In B.C. 119 he was elected tribune of the plebs, through the influence of Cæcilius Metellus, according to Plutarch, but more probably in consequence of the fame he had acquired in the Numantine war. In this office he showed himself, as he did throughout the whole of his life, a most determined enemy to the patrician order, and one who was not easily to be put down by the threats and opposition of his enemies. Having proposed a law to prevent illegal voting at elections, the senate passed a decree that the law should not be put to the vote in the popular assembly, and summoned Marius before them to answer for his conduct. Marius not only appeared, but threatened to commit the consuls to prison, if they did not repeal the decree; and when Metellus continued to support it, he commanded him to be led away to prison.

Marius obtained the prætorship with great difficulty, in consequence of the violent opposition of the patrician order, who accused him of having obtained the office by means of bribery. At the expiration of his prætorship the province of Spain was assigned to him, which he cleared of robbers. On his return to Rome, he was anxious to obtain the consulship; but he did not venture to become a candidate for many years after. He continued however to rise in public opinion, and appears about this time to have married Julia, one of the Julian family, who was aunt to the celebrated Julius Cæsar.

In B.C. 109 he accompanied Metellus into Africa in the capacity of *legatus* (second in command); and by his prudence and courage in the war with Jugurtha he added greatly to his military reputation. His friends took advantage of his increasing popularity at Rome to persuade the people that the war with Jugurtha would never be concluded until the command was given to Marius. This led to an open rupture between him and Metellus; and it was with the greatest difficulty that Metellus allowed his lieutenant leave of absence to go to Rome in order to stand for the consulship. Marius was however successful; he obtained the consulship (B.C. 107) and the command of the Jugurthine war. On his arrival in Africa, Marius prosecuted the war with the greatest vigour; and in the following year (B.C. 106) obtained possession of the person of Jugurtha, who was treacherously given up by Bocchus to his quæstor Sulla. [JUGURTHA.] Marius remained in Africa during the next year (B.C. 105); in which the consul Manilius and the proconsul Cæpio were defeated by the Teutones and Cimbri in Gaul, with the prodigious loss, according to Livy (*Ep.* 6[illegible] of 80,000 soldiers, besides 40,000 camp-followers. The news of their defeat caused the greatest consternation at Rome, especially as the Teutones and Cimbri threatened the immediate invasion of Italy; and Marius was accordingly elected consul in his absence, without any opposition even from the patrician party, as the only man in the state who was able to save it from impending ruin.

Marius entered upon his second consulship B.C. 104, and triumphed on account of his victories over Jugurtha; but in consequence of the threatened invasion of Italy having been deferred by an irruption of the Cimbri into Spain, Marius was again chosen consul in the two following years (B.C. 103, 102). In the fourth consulship of Marius (B.C. 102) the Cimbri, having been defeated by the Celtiberi in Spain, returned to Gaul, and resolved to invade Italy in two divisions; the one, consisting of the Teutones and Ambrones (a Gallic people), through Gallia Narbonensis; and the other, comprising the Cimbri, by way of Noricum. Marius defeated the Teutones and Ambrones near Aquae Sextiae (*Aix*) in Gaul; but Catulus, who was stationed at the foot of the Alps to oppose the passage of the Cimbri, retreated first to the other side of the Athesis (*Adige*), and afterwards quitted this position also without waiting for the enemy's attack. In the following year, B.C. 101, Marius, who was again elected consul, for the fifth time, joined his forces with those of Catulus, and entirely defeated the Cimbri in the plain of Vercellae (Vercelli), situated to the north of the Po, near the Sessites (Sesia). In these two battles the Teutones and Ambrones are said to have lost the incredible number of 290,000 men (200,000 slain and 90,000 taken prisoners); and the Cimbri 200,000 men (140,000 slain, and 60,000 taken prisoners). (Livy, *Ep.* 68.)

Marius again became candidate for the consulship for the following year; but now that the fear of the Gallic invasion was removed, he was opposed by the whole strength of the patrician party. He nevertheless obtained the consulship, in great part owing to the exertions of Saturninus, the tribune, who is described as a man who scrupled at the commission of no crime in order to obtain his object. The events of the sixth consulship of Marius, which are some of the most important in this period of Roman history, are superficially narrated by the historians. It appears that an Agrarian law, proposed by Saturninus and supported by Marius and one of the praetors named Glaucia, was carried notwithstanding the most violent opposition of the patrician party; and that Metellus Numidicus was driven into exile in consequence of refusing to take the oath of conforming to the law. When the election of consuls for the ensuing year came on, Memmius, who opposed Glaucia as a candidate for the office, was murdered by order of Saturninus; and the senate, perceiving the city to be in a state of anarchy, passed the usual decree, 'that the consuls should take care that the republic should receive no injury,' by which almost absolute power was vested in the consuls. Marius, unable or unwilling to protect his old friends, besieged Saturninus and Glaucia, who had seized upon the capitol. They surrendered themselves to Marius on the promise that their lives should be spared, but they were all immediately put to death. It appears probable that Marius, after the blow which had been given to the popular party by the surrender of Saturninus and Glaucia, would not have been able to save their lives, even if he had made the attempt.

At the expiration of his consulship, Marius left Rome to avoid witnessing the triumph of the patrician party in the return of his old enemy Metellus, whose sentence of banishment was repealed after the death of Saturninus. According to Plutarch, Marius went to Cappadocia and Galatia, under the pretence of offering a sacrifice which he had vowed to Cybele; but with the real object of exciting Mithridates to war, in order that he might be again employed in military affairs, since he did not obtain much distinction in peace.

In B.C. 90 the Marsian or Social war broke out; in which both Marius and Sulla were engaged as legati to the two consuls. Marius gained several victories over the enemy, but he no longer possessed that activity and energy which had distinguished him in his earlier years; and disgusted, it is said, with the increasing reputation of Sulla, he resigned his command before the conclusion of the war.

The Marsian war had scarcely been brought to an end, before the civil war broke between Marius and Sulla. The command of the Mithridatic war had been assigned to Sulla, who was now consul (B.C. 88); but Marius used every effort to wrest it from him, and is said by Plutarch to have gone every day to the Campus Martius, and to have performed his exercises with the young men, although he was now in his 70th year and very corpulent, in order to show that he was not incapacitated by age. He was warmly supported by P. Sulpicius, the tribune, who possessed great property and influence; and a law was eventually passed that the command should be taken from Sulla and given to Marius. Sulla was with the army at the time besieging Nola; but as soon as he heard of the law which had been passed, he marched to Rome; and Marius and his adherents were obliged to quit the city. After wandering through many parts of Italy, Marius escaped with the greatest difficulty to Africa; but he had no sooner landed at Carthage, than Sextilius, the governor of the province, sent word to him, that unless he quitted Africa, he should treat him as a public enemy. 'Go and tell him,' replied Marius, 'that you have seen the exile Marius sitting on the ruins of Carthage.' But in the following year (B.C. 87), in the absence of Sulla, who had gone to Greece to oppose Archelaus, Marius returned to Italy in order to join the consul Cinna, who, in his attempts to abrogate the laws of Sulla, had been driven from Rome by his colleague Octavius, supported by the patrician party. Shortly afterwards Marius and Cinna entered the city at the head of a large army; and a general massacre of the opposite party ensued. Marius always appears to have been of a fierce and unrelenting temper; and the sufferings he had lately undergone, which at his time of life must have greatly impaired his health, tended to exasperate him more than ever against the party which had opposed and thwarted him during the whole of his life. All the leaders of the patrician party who were unable to escape from Rome were put to death: Lutatius Catulus, who had been the colleague of Marius in the war with the Cimbri, put himself to death in order to avoid assassination; and among the numerous illustrious patricians who fell were Q. and L. Julius Caesar, and the celebrated orator M. Antonius, who is so frequently praised by Cicero, and is one of the principal speakers in the treatise 'On the Orator.'

Marius and Cinna declared themselves consuls for the ensuing year (B.C. 86), without even holding the comitia; but Marius died of a fever in the beginning of the year, on the 17th day of his consulship, according to Plutarch (c. 46), or the 13th, according to Livy (*Ep.* 80).

The character of Marius is chiefly known to us from his life by Plutarch, who appears to have taken his account from the 'Memoirs of Sulla,' the inveterate enemy of Marius. It cannot be denied that after his return from exile Marius was guilty of the greatest cruelties, but even these were surpassed by the atrocities of Sulla; and we should not be doing justice to Marius, if we ascribed to him, during the whole of his life, the character which he displayed in his seventh consulship. 'I have seen,' says Plutarch (c. 2), 'the statue of Marius at Ravenna in Gaul, which expresses in a remarkable manner his sternness and severity. Since he was naturally robust and warlike, and more acquainted with the arts of war than those of peace, he was fierce and haughty when in authority. It is said that he never learnt Greek, and that he would not make use of that language on any serious occasion; as if it were ridiculous to learn the language of a people who were subject to others. If he could have been persuaded to pay his court to the Grecian muses and graces, he would not, after bearing so many honourable offices and performing so many glorious exploits, have crowned the whole by a most savage and infamous old age, in consequence of his yielding to anger, ill-timed ambition, and insatiable avarice.'

(Plutarch's *Life of Marius*; Sallust's *Jugurthine War*; *Epitomes* of Livy; Velleius Paterculus; Cicero, *De Oratore*, iii. 2, 3; Clinton's *Fasti Hellenici*.)

MARIVAUX, PIERRE CARLET DE CHAMBLAIN DE, born at Paris, in 1688, was one of the most popular romance writers of the eighteenth century, and one to whom that branch of literature is mainly indebted for the character and authority which it has acquired as a representation of actual life and manners, illustrated by the analysis of conduct and motives, sentiments and feelings. He began his career as a dramatic writer, and his pieces were for a long time the support of the Théâtre Italien. Yet although they display much ingenuity and talent, and procured for their author a seat in the French Academy, they now possess little interest, except as being productions of the same pen which gave the world 'La Vie de Marianne,' and the 'Paysan Parvenu.' Marivaux also wrote another romance, entitled 'Pharsamon,' every way inferior to the two on which his reputation rests; also 'Le Spectateur François,' and 'Le Philosophe Indigent.' The inequality of his taste was also manifested by his 'Homère Travesti,' which was published in 1716, was neglected from the very first, and has long been deservedly forgotten; while his two novels still charm by the master-touches with which they abound, by their accurate and highly finished delineations of character, and by the intimate knowledge which they display of the human heart. Marivaux was no less estimable as a man than as an author. He was not one of those who put on morality as a holiday suit when they show themselves in public; he did not, like Sterne, dip merely his pen in sentiment; nor was he, as too many others have been both before and since, the eloquent advocate of a philosophy which his own conduct belied. On the contrary, his life illustrated the lessons which he endeavoured to impress upon others. Benevolence to all, active sympathy for the unfortunate, and a philosophic indifference towards wealth and distinctions, were prominent traits in his character. He died at Paris in 1763.

MARJORAM, an aromatic potherb, used in cookery, especially among the French. It is the Origanum Majorana of Linnæus, or Majorana hortensis of Mœnch, a native of Barbary and the Himalaya mountains. In gardens it is little better than an annual; in a wild state it is a suffruticose perennial.

MARK. [Money.]

MARK, ST., the Evangelist, is supposed by the greater number of antient and modern writers to be the same person as John Mark, who is mentioned in the 'Acts of the Apostles' (xii. 12, 25; xiii. 5, 13; xv. 37). It is most probable that John was his Jewish name, and that he took the surname of Marcus when he went to preach among the Gentiles. He was the son of Mary, a pious woman at Jerusalem, in whose house the disciples were wont to meet (*Acts*, xii. 12), and the nephew of Barnabas (*Col.* iv. 10). He left Jerusalem with Paul and Barnabas, about A.D. 44 (*Acts*, xii. 25), and accompanied them in their return to Antioch, and thence in their mission (*Acts*, xiii. 5) as far as Perga in Pamphylia, where he parted from them and returned to Jerusalem (*Acts*, xiii. 13). About A.D. 53 we find him again at Antioch, when Paul proposed to Barnabas to visit the Asiatic churches. Barnabas wished to take Mark with them, but Paul refusing on account of his having deserted them in their former journey, they separated from each other, and Mark accompanied Barnabas to Cyprus (*Acts*, xv. 37-39). Paul appears to have been reconciled to him afterwards, for we find him at Rome with the apostle during his imprisonment, and he is honourably mentioned in some of Paul's Epistles (*Col.* iv. 10; *Philemon*, ver. 24; 2 Tim. iv. 11). We also find him with Peter in Asia (1 *Pet.* v. 13; see Steiger's 'Commentary on the First Epistle of Peter,' *in loco*); and it is supposed that he accompanied that apostle to Rome. According to Eusebius, Epiphanius, and Jerome, he afterwards went to Egypt, and founded a church at Alexandria, where he died and was buried, according to Jerome, in the eighth year of Nero's reign, A.D. 62. But this date appears to fix his death earlier than other circumstances in his history will warrant.

All the early writers affirm that Mark was intimately acquainted with St. Peter: Papias, Irenæus, and Tertullian call him 'Peter's interpreter.' It has been supposed that he was converted to Christianity by St. Peter, as that apostle calls him 'my son' (see Kuinoel's note on *Matt.* xii. 27). Some of the later Fathers mention him as one of the seventy evangelists; but there is no good authority for this tradition, and it is contradicted by Papias, who expressly says that he had heard from the presbyter John, who was contemporary with the apostles, that Mark was not a hearer nor a follower of Christ, but of Peter. (Eusebius, *Ecc. Hist.*, iii. 39.)

MARK, ST., THE GOSPEL OF. The genuineness and authenticity of this Gospel are attested by the unanimous voice of ecclesiastical writers. Michaelis has indeed objected to its canonical authority, in common with that of Luke, but on no good ground. [Luke, Gospel of.] According to Papias, Irenæus, and other early writers, Mark committed to writing the gospel which was preached by Peter; and Clement of Alexandria states that he did so at the request of Peter's hearers at Rome. Other early writers add that in this work Mark had the approbation and assistance of Peter; and many passages of the gospel have been thought to bear traces of being written under Peter's direction. From the tradition mentioned above, and from Latinisms and explanations of Jewish phrases and customs contained in Mark's gospel, it appears to have been written at Rome for the benefit of the Latin Christians.

The time when it was written is uncertain. Irenæus says that it was composed *μετὰ τὴν τούτων* (Peter and Paul) *ἔξοδον*; but whether he means *after the death* of Peter and Paul, or *after their departure* from Rome, is a question much disputed. Upon the whole, the most probable date appears to be about A.D. 64 or 66.

According to the unanimous testimony of the early ecclesiastical authors, the gospel of Mark was written in Greek. The Latin MS. at Venice, said to be part of St. Mark's *autograph*, has long since been proved to be nothing of the kind.

The contents of St. Mark's gospel have been divided into the three following parts:—

Part I. The baptism and temptation of Christ (i. 1-13).

Part II. The public ministry of Christ, up to his last journey to Jerusalem (i. 14—x.).

Part III. Transactions at Jerusalem, the death, resurrection, and ascension of Christ (xi.—xvi.).

The opinion that Mark's gospel is an abridgment of Matthew's has been satisfactorily refuted by Michaelis; for notwithstanding the coincidences between these two gospels, we find, on comparing them, that there are in Mark omissions of and discrepancies with what is contained in Matthew, which it is difficult to account for on the supposition that he wrote with the gospel of Matthew before him. The true mode of explaining these coincidences and discrepancies belongs to the more general question respecting the origin of the first three gospels. [Gospel.] Those who believe that each evangelist composed his narrative from independent sources of information have no difficulty in proving Mark's qualifications for the task; for besides the assistance which he probably received from Peter, what we know of his life proves that he must have had opportunities of constant intercourse with the apostles and first Christians.

(Lardner's *Credibility* and *Lives of the Apostles and Evangelists*; Cave's *Lives of the Apostles and Evangelists*; Kuinoel, *Comment. in Lib. Hist. N. T.*, *Proleg. in Marc.*; the *Introductions* of Michaelis, De Wette, Hug, and Horne.)

MARKET (*mercatum*), a public place and fixed time for the meeting of buyers and sellers. A legal market can exist only by virtue of a charter from the crown or by immemorial user, from which it will be presumed that a royal charter once existed, although it can be no longer produced. A market is usually granted to the owner of the soil in which it is appointed to be held, who, as such grantee, becomes the owner, or lord, of the market. In upland towns, that is, towns which, not being walled, had not attained the dignity of boroughs, markets were frequently granted to lords of manors; but in walled towns or boroughs, particularly in such as were incorporated, the ownership of the soil having usually, by grant from the crown, or other lords of whom the borough was originally holden, been vested in the incorporated burgesses, the course has commonly been to grant markets to the municipal body.

The prerogative of conferring a right to hold a market is however subject to this limitation, that the grant must not be prejudicial to others, more especially to the owners of existing markets. In order that the crown may not be surprised into the making of an improper grant, the first step is, to issue a writ ad quod damnum, under which the sheriff of the county is to summon a jury before him to inquire whether the proposed grant will be to the damage of the king or of any of his subjects. This writ must be executed in a fair and open manner, and the sheriff is bound to receive evidence tendered against, as well as in favour of the grant. But as the writ does not purport to affect the interest of any person in particular, it is not necessary that notice should be given of the time or place at which it is meant to be executed. Notwithstanding a finding by the jury that the proposed market will not be injurious, any party who conceives that his interests are affected by the grant when made, whether he appeared upon the inquiry under the writ ad quod damnum or not, may traverse the finding, or sue out a writ of scire facias, which, after reciting the alleged injury, calls upon the grantee, in the name of the crown, to show cause why the grant should not be cancelled. If a new market be set up without any grant from the crown, the party is liable to be called upon by the crown to show by what warrant he exercises such a franchise [Liberty; Quo Warranto]; and he is also liable to an action on the case for damages, at the suit of any person to whose market, or to whose property, the market so set up by the defendant is a nuisance. A new market is presumed to be injurious is another held within the distance of twenty miles, even though it be on a different day, but this presumption may be rebutted.

Formerly markets were held chiefly on Sundays and holidays, for the convenience of dealers and customers, brought together for the purpose of hearing divine service. But in 1285, by 13 Edward I., c. 5, fairs and markets were forbidden to be held in churchyards; and in 1448, by 27 Henry VI., c. 5, all showing of goods and merchandise, except necessary victuals, in fairs and markets, was to cease on the great festivals of the church, and on all Sundays, except the four Sundays in harvest. The holding of fairs and markets for any purpose on any Sunday was prohibited in 1677, by 29 Charles II., c. 7.

The grantee of a market has a court of record called a court of pie-powder (pieds poudreux, 'dusty feet'), for the prompt decision of matters arising in the market. [Piepowder Court.] Such a court being considered necessary for the expedition of justice and for the support of the market, the power of holding it is incident to a grant of a market, even though the royal letters patent by which the grant is made be entirely silent on the subject.

Sales in markets may be of goods actually brought within the precincts of the market, or of goods not so brought. Goods not within the precincts of the market are sold sometimes by sample, sometimes without sample. Where goods are usually brought into the market for sale, it is incumbent on the lord of the market to take care that every thing be sold by correct and legal weights and measures.

For the security of dealings in markets, contracts were formerly required to be made in the presence of an officer appointed for that purpose by the lord of the market, for which service he received from the buyer a small remuneration called market-toll. [Toll.]

It is a rule of the common law that every sale in market-overt (open market) transfers to the buyer a complete property in the thing sold; so that however defective the title of the vendor may be, yet that acquired by the vendee is perfect, even where the property belongs to a person who is under legal disability, as an infant, a married woman, an idiot, or a person in prison or beyond sea. In London every shop is market-overt for goods usually sold there.

This rule is subject to certain exceptions and restrictions. A sale in market-overt does not bind the rights of the crown; nor does it bind the rights of others, unless the sale be in an open place, as a shop, and not a warehouse or other private part of the house, so that those who go along cannot see what is doing, and not in a shop with the shop-door or windows shut, so that the goods cannot be seen. The articles bought must be such as the party usually deals in. The sale must be without fraud on the part of the buyer, and without any knowledge on his part of any want of title in the vendor. If the seller acquire the goods again, the effect of the sale in barring the true owner is defeated. There must be a sale and contract; and therefore the property is not altered in market-overt in goods given, or in goods pawned, or in goods sold to the real owner. The sale must be between sunrise and sunset, and must be commenced and completed in the market.

By 21 Henry VIII., c. 11, 'If any felon rob or take away money, goods, or chattels, and be indicted and found guilty, or otherwise attainted upon evidence given by the owner or party robbed, or by any other by their procurement, the owner or party robbed shall be restored to his money, goods, or chattels.' Since this statute, stolen goods, specified in the indictment, have, upon the conviction of the offender, been restored to the prosecutor, notwithstanding any sale in market-overt.

As stolen horses can be easily conveyed to distant markets, the legislature has frequently interposed to protect the owner against the consequences of a sale in market-overt. By 2 and 3 Philip and Mary, c. 7, 'No sale of a horse stolen binds the property, unless it stand or be ridden an hour together between ten o'clock and sunset, in an open part of the market, and all parties to the bargain come with the horse to the book-keeper and enter the colour, and one mark, at the least, of the horse sold, and pay the toll, if any due, else a penny.' And further, by 31 Elizabeth, c. 12, 'No person shall in any fair or market sell, give, exchange, or put away any horse, mare, &c., unless the toll-taker, book-keeper, bailiff, or other chief officer will take upon him perfect knowledge of the person that shall so sell, give, or exchange any horse, &c., and of his true name, surname, and dwelling-place, and shall enter the same in a book there kept for sale of horses, or else that he so selling or offering to sell, &c. any horse, &c., shall bring unto the toll-taker or other officer aforesaid of the same fair or market, one sufficient and credible person, that can testify before such toll-taker, &c., that he knows the party that so sells, &c., such horse, &c., and his true name, surname, mystery, and dwelling-place, and there enter in the book of the toll-taker or officer, as well the true name, surname, mystery, and place of dwelling of him that so sells, &c., such horse, &c., as of him that so shall testify his knowledge of the same person, and shall also enter the true price that he shall have for the same horse, &c., and that no toll-taker, &c., shall take toll or make entry of any sale, &c., of any horse, &c., unless he knoweth the party that so sells, &c., such horse, &c., and his true name, surname, mystery, and place of dwelling, or the party that shall testify his knowledge of the same person so selling, &c., any such horse, &c., and his true name, &c., and shall make a perfect entry in the book of such his knowledge and of the true price taken or had for any such horse, &c., so sold, &c., so far as he can understand the same; and then give to the buyer a note in writing of the full contents of the same, subscribed with his hand; on pain that every person that shall so sell, &c., any horse, &c., without being known to the toll-taker, &c., or without bringing such witness, or causing the same to be entered as aforesaid, and every person making any untrue testimony, and every toll-taker, &c., offending in the premises, shall forfeit 5*l.*, and that every sale, &c., of any horse, &c., in fair or market not used in all points as aforesaid shall be void.' And by sect. 4, 'If any horse, &c., be stolen, and afterwards sold in open fair or market, and the sale shall be used in all points and circumstances as aforesaid, yet the sale of any such horse, &c., within six months after the felony, shall not take away the property of the owner, so as claim be made within six months, before the mayor or other head officer of the town or parish, if the horse, &c., happen to be found in any town corporate or market-town, or else before any justice of peace of the county near to the place where such horse, &c., shall be found, if it be out of a town corporate or market-town, and so as proof be made within forty days, by two sufficient witnesses, before such head officer or justice, that the property of the horse, &c., so claimed, was in the party by whom such claim is made, and was stolen within six months next before such claim, but that the party from whom the horse, &c., was stolen may at all times after, notwithstanding any sale in fair or market, have property and power to take again the said horse, &c., upon payment or offer to pay the party that shall have the possession and interest of the same horse, &c., if he will accept it, so much money as the party shall depose and swear before such head officer or justice of peace, that he paid for the same *bonâ fide* without fraud or collusion.' This statute extends to a horse taken by wrong, though it be not stolen.

By 1 James I., c. 21, 'No sale, exchange, pawn, or mortgage, of any jewels, plate, apparel, household stuff, or other goods, wrongfully purloined, taken, robbed, or stolen, and sold, uttered, delivered, exchanged, pawned, or done away, within London and its liberties, or Westminster, or Southwark, or within two miles of London, to any broker or pawn-taker, shall work or make any change or alteration of the property or interest.'

A market is generally appointed to be held once, twice, or three times in a week, for the current supply of commodities, mostly of provisions. A large market held once or twice a year is called a fair; and, according to Lord Coke, a large fair held once a year is a mart.

Fairs have all the legal incidents of markets, and are subjected to further regulations by 2 Edw. III., c. 15, one of which requires, that at the opening of the fair, proclamation be made of the time it is to continue.

MARKETS, AGRICULTURAL. The more numerous markets are in any well cultivated country, provided they are at a sufficient distance not to interfere with each other, and on different days of the week, the greater saving there is of time and labour of conveyance. Good roads or navigable rivers are of great importance to a market-town; and if there are mills in the neighbourhood, where corn can be ground, they will increase the advantage to the farmer by causing a regular demand above what the immediate consumption of the place may require.

The vicinity of a good market where every kind of agricultural produce will always find purchasers at a fair price, greatly adds to the value of a farm, especially if good roads lead to it; and the advantage is the greater if it be a populous town, which not only consumes much produce, but from which various kinds of manure may be brought by the teams which have carried the produce to market. It is this which so much enhances the rent of land near London and all great cities, and makes the agriculture there approach nearer to horticulture, which entirely depends on extraneous manure.

Few things are so bulky as corn; a sack weighing 240 lbs. when brought to market may be worth a guinea or thirty shillings, but if it is carred 50 miles to a market, the net value will be much reduced; and if at that market there is no demand beyond what is required for the immediate neighbourhood, and no means of exportation, a very small surplus will glut it, and reduce the price still lower. The nature and situation of the markets are consequently a most important consideration in any agricultural enterprise. Where markets are very distant, the only profitable produce is live-stock, which can be driven a long way at a small expense. All countries, however fruitful the soil, which are thinly peopled, and have no ready markets for corn, must necessarily remain in pasture or be uncultivated. An increase in the population and the establishment of manufactures give rise to an increased number of markets, and bring more land into a state of profitable cultivation as arable land. If a regular supply of food is essential in a manufacturing population, so the demand for it causes more to be produced. A regular supply to the markets keeps prices regular, fluctuating only according to the abundance or scantiness of the crops.

It is for the general advantage that the farmers should bring their corn in regularly, without speculating on a rise or fall of prices. As a general principle, a farmer should thrash his corn at a time when the work out of doors is less important, or when the weather is unfavourable for it. He must do so whenever the fodder for his cattle diminishes, and a fresh supply of straw is required: and as soon as the grain is in sufficient quantity to require a team to take it to market, it should be sold. But many circumstances may make this regular course inconvenient. There may not always be a demand for the article, and if a sale is forced, a diminution in the price must be submitted to. In some situations purchasers cannot always be found, at any price, and a granary to store corn in becomes indispensable. In commercial countries there are always speculators in corn, who make their profit by buying and selling the commodity. The farmer is tempted to withhold his corn when the price is low, in order to have a greater profit when it rises; and, to a certain degree, he is justified in doing so: but if he speculates on his own corn, when he can obtain a fair price for it, he becomes a merchant, as much as if he purchased to sell at a profit. When there is a good market at hand, the produce of the farm should be regularly sold, so as to give the farmer a constant supply of money for his operations, besides a portion set apart for the rent and other regular payments. In this way he will, at the end of the year, have had the average price, without risk and without speculation; and by a little caution he may obtain somewhat more than a mere average, provided he has always more money at hand than his immediate wants require, and is never forced to sell.

In order that the farmer may not be imposed upon, he must either make himself acquainted with the transactions in different neighbouring markets, or he must rely on the honesty and judgment of an agent, whose business it is to attend markets and buy and sell for others. These men are generally called salesmen or factors, and when their character for honesty is established, the small sum which is paid them on the sales will generally be found to be fully compensated by the advantage which their knowledge of the markets and of the quality of the articles gives them. This is particularly the case in the buying and selling of live-stock, which requires much more knowledge and experience than most other articles. The people whom the farmer has to deal with in fairs and markets have generally a thorough knowledge of the real value of the articles offered for sale, by constantly frequenting markets, and confining their attention to buying and selling only. The farmer is therefore seldom a match for the dealer, and will find it his interest to employ a person equally skilled in these matters. The farmer would lose too much valuable time, and be led to unnecessary expense, if he attempted to obtain the requisite knowledge, by frequenting different and distant markets, as the dealers do

Notwithstanding this, a certain knowledge of markets and prices is necessary to enable a farmer to detect imposition or ignorance in the person he employs, and the occasional attendance at fairs and markets is indispensable to obtain this knowledge.

When the whole bulk of the articles to be sold is brought into the market and exposed for sale, the market is called a *pitched* market; when only a small portion is brought, to show the quality of the whole, it is called a *sample* market. Each has its peculiar advantages and inconveniences. In a pitched market the buyer sees what he purchases, and can thoroughly examine it; he may therefore be induced to offer a more liberal price; but it often happens that he has to carry a load away by the same road by which it was brought; the sacks also have to be returned, which causes frequent mistakes and losses; and there is an evident waste of time and labour. When the article is sold by sample there is more reliance on the honesty of the seller, and the buyer naturally keeps on the safe side, by offering somewhat less, as a kind of insurance against slight deceptions. The buyer keeps half the sample and the seller the other, that they may be compared with the bulk in case of any dispute. The seller sends the article sold on a day agreed upon; and if it is corn the sacks are brought back when the waggon or cart returns home. The price is usually paid on the next market-day. In very large dealings the selling by sample is generally adopted; small quantities are usually pitched.

Great inconvenience arose formerly from the various measures used in different markets; and dealers required tables to reduce them to one standard. The law which has established one uniform standard of weights and measures has removed all difficulty, and the rapid and frequent communications which now take place between the great towns and every inhabited spot in the kingdom have made prices much more nearly alike, for all articles of general necessity in all parts of Great Britain, than in any other country; and the prices in the markets of the great towns differ so little, that in the country these are generally regulated by those of London, Liverpool, or Edinburgh. Every farmer who cultivates land to any extent must attend to the fluctuations of the markets, and his operations may be much influenced by the comparative prices of different kinds of grain.

MARKLAND, JEREMIAH, was born the 29th of October, 1693, at Childwall, in Lancashire, of which his father was vicar. He was educated at Christ's Hospital, London, whence he was sent to St. Peter's College, Cambridge, in 1710. He took his degree of M.A. in 1717, and was soon afterwards elected a fellow and tutor of his college. After residing at Cambridge for some time, he removed to Punsborn, in Hertfordshire, to undertake the education of Mr. Shode's son, and afterwards travelled with his pupil on the Continent. During the latter part of his life he resided at a small village near Dorking, in Surrey, where he died on the 7th of July, 1776.

Markland lived in the greatest retirement, and devoted a long life to the diligent study of the Greek and Roman writers. He was one of the best English scholars and critics of the last century, but wrote very little. He edited the 'Sylvæ' of Statius (Lond., 1728), the 'Supplices' (1763), and the two Iphigenias of Euripides (1771), which have been republished by Gaisford. Subjoined to his edition of the 'Supplices' are his 'Explicationes veterum aliquot Auctorum.' He also contributed some observations to Taylor's edition of Lysias, to Bowyer's reprint of Küster on the Middle Verb in Greek, and to Musgrave's edition of the 'Hippolytus.' In 1745 he published 'Remarks on the Epistles of Cicero to Brutus, and of Brutus to Cicero, in a Letter to a Friend:' in which he attempts to prove that they could not have been written by Brutus or Cicero; and in an Appendix to this work he also maintains that the four orations which occupy a place in Cicero's works, under the titles of 'Pro Domo sua apud Pontifices,' 'De Haruspicum Responsis,' 'Post Reditum in Senatu,' and 'Ad Quirites post Reditum,' are also spurious. This opinion has been supported by F. A. Wolff and many other able critics.

MARL. A mixture of calcareous and argillaceous earth is commonly called marl; in Norfolk soft chalk used on the lands is called marl; in Worcestershire and Somersetshire red clays are termed marls. In geology we have the red marl, the black marl at the base of the lias, the chalk marl, the freshwater marls of Headon Hill in the Isle of Wight. The term is too vague for scientific descriptions.

MARL, an earthy substance found at various depths under the soil, and extensively used for the improvement of land. It consists of calcareous and argillaceous earth, in various proportions, and as the former or the latter prevails, so it is beneficially employed on clays or sands. There are several distinct sorts of marl—clay marl, shell marl, slate marl, and stone marl. The clay marl has probably been formed by the slow deposition of clay suspended in water and mixed with the particles of decomposed shells. When these shells have retained their form, or appear in fragments in the marl, it is called *shell marl*. A considerable compression and a complete decomposition of the shells form slate marl and stone marl. The effect of marl is the same as that of clay and chalk upon sandy soils; on heavy soils its effect is proportioned to the quantity of calcareous earth which it contains. The peculiar advantage of marl is its readily crumbling to powder by the effect of air and moisture. If it is too compact to dissolve under these influences, it can only be made useful by burning, and in this case it is only a substitute for lime, its value depending on the proportion of calcareous earth in the marl. To ascertain this proportion, the marl is thoroughly dried over the fire and pulverised; a certain quantity is weighed and put into a cup; diluted nitric acid or strong vinegar is poured slowly upon it, out of a vessel containing a known quantity, until all effervescence ceases. A quantity of the acid equal to that which has been used is placed in a cup, and fine marble dust is gradually put into this, from a certain quantity which has been weighed, as long as any effervescence appears. The weight of the marble dust used for this purpose evidently gives the quantity of calcareous earth in the marl, since it takes the same quantity of acid to dissolve it.

Marl is often found very near the surface, so as to mix with the soil in ploughing; but unless there be a sufficient depth of soil above, its presence does not indicate great fertility. It is generally best when found at a moderate depth, so as to be readily dug out and carted on the adjacent lands. In Norfolk, where a marl containing a large proportion of clay is found in many places under a light soil, it is frequently spread over the surface at the rate of two or three hundred cart-loads per acre. This dressing, joined to underdraining, makes a wonderful improvement on soils which before were scarcely worth cultivating, owing to their being loose and wet in winter. The clay marl makes them retain sufficient moisture, while the superfluous water is carried off by the drains.

Marl being often found with blue veins through it, a marbled earth containing sulphate of iron, or vitriol, has sometimes been mistaken for it; but this, far from being useful, is quite the reverse; for sulphate of iron in any quantities will produce absolute sterility in a soil. The nature of marl can always be detected by pouring a little vinegar on it; if it does not effervesce, it is only clay, and probably contains iron, which is readily discovered by the red colour on burning a portion in the fire, or by mixing it with water and then adding an infusion of gall-nuts in the strained liquor: the black colour immediately detects the sulphate of iron.

Marl when put fresh upon the land requires some time in order to become effective. It should therefore be laid on the surface and spread before winter, leaving it there for a considerable time before it is ploughed in. It is most advantageous to put it on the land when it is in grass, and to roll and harrow it repeatedly, in order to expose it to the effect of the air and rains. Alternate frosts and thaws greatly assist its pulverisation.

Too much marl may be put upon land, and it is better to repeat the marling after a few years than to put on a great quantity at once. The proper dose depends on the nature of the soil and that of the marl. Sand will take a very large quantity of clay marl; but even shell marl should be put cautiously on clay soils; they may not always be improved by a great addition of calcareous matter. There is no greater mistake than to imagine that marl is a substitute for dung. Light land which has been marled becomes less hungry, and marl will make dung go further, but it will not act well on a poor soil without dung; and if the land is severely cropped after marling, and not sufficiently recruited with enriching manures, it will be sooner exhausted than if it had not been marled; for marl, like lime, renders soluble the natural humus in the soil.

It is very easy to judge of the value of any marl on a given soil when the proportion of calcareous earth and clay in its composition has been ascertained. We have only to consider what improvement will be produced in the texture by the addition of so much lime and so much clay. The advantage of marl over pure chalk is only that it is more readily pulverised; but wherever chalk can be had at an equal expense, it is far more effectual and of longer duration on clay soil than the best marl. On sands it may be different, and the fat marls containing much unctuous clay are preferable from their binding nature.

An excellent use of marl is in forming composts with dung and peat earth. It is laid in layers with the dung and peat, and if the heap is well soaked with urine or the washings of stable-yards, it will in a short time become a most valuable manure for all kinds of soils. Many peat bogs are formed on a marly bottom; where this is the case, and it can be drained, or the water got rid of in any way, the marl, when laid on the surface, consolidates the peat by its pressure, and soon makes it capable of producing good herbage by converting it into a rich vegetable mould.

The expense of marling land can only be calculated when the distance of the marl and the depth from which it is raised are known; when it lies in a stratum under the land, it is generally the cheapest plan to open a pit in each field; for the carriage of the marl is the chief expense. Within a distance of two hundred yards from the pit, it is found by experience that the cheapest way of putting it on the land is by means of men wheeling it in barrows with the help of planks, as is done in digging canals and other similar public works.

MARLBOROUGH. [Wiltshire.]

MARLBOROUGH, JOHN CHURCHILL, DUKE OF, the ablest general and most consummate statesman of his times, was born at Ashe in Devonshire, on the 24th of June, 1650. He was the second son of Sir Winston Churchill, a gentleman of antient family, whose fortunes had suffered severely in the civil war, through his devotion to the royal cause; and whose loyalty, after the Restoration, was rewarded with sundry small offices under the crown for himself, and with the more questionable benefit of appointments for his children in the profligate court of Charles II. Arabella Churchill, his daughter, became first maid of honour to the Duchess of York, and next mistress to her husband the Duke, afterwards James II.; and John Churchill, who was appointed page to the same prince, doubtless owed his early advancement to this disgraceful connection. It is remarkable that one of its fruits, James FitzJames, duke of Berwick, proved a commander of renown only less illustrious than his maternal uncle.

The natural talents and merits of Churchill however were of too high an order to be solely dependent on the patronage which had sullied the honour of his house. Notwithstanding the disadvantages of a neglected education, which seems to have been confined to a short residence at St. Paul's school, he gave early indications of spirit and intelligence; and his desire for a military life having been gratified by his patron with a commission, he invariably distinguished himself in each of his early campaigns: in the defence of Tangiers against the Moors; and in the successive operations in which the English troops shared as auxiliaries to the French armies under Louis XIV. during the unprincipled alliance of Charles II. with that monarch against the Dutch. On the great theatre of continental warfare, in which Churchill continued to serve from 1672 to 1677, his brilliant courage and ability, no less than the singular graces of his person, attracted the notice of the illustrious Turenne, who pronounced, with prophetic sagacity, that 'his handsome Englishman' would one day prove himself a master of the art of war.

On the conclusion of the peace of Nimeguen, Churchill, now a colonel, returned to England, and was happily rescued from too licentious a career of dissipation by an ardent attachment for the celebrated woman who became his wife, and who, for good and evil, influenced the whole tenor of his subsequent life. This was Sarah Jennings, a young lady of birth, genius, and beauty, whose irreproachable purity in a vicious age might have rendered her worthy of the uxorious love of the hero, if her imperious temper had not disgraced his submission to its tyranny, alienated his political friends, and embittered his domestic peace. She had been placed, like himself, at an early age, in the household of the Duke and Duchess of York, where she had become the favourite associate of their daughter the Princess Anne, and had acquired over the spirit of the future queen that commanding influence which it belongs to the stronger to exercise over the weaker mind. Her marriage separated neither her husband nor herself from their service in the ducal household; Churchill was confidentially employed by the Duke of York on many political occasions; and when the Princess Anne was married, his wife was, by her express desire, made a lady of her bedchamber. Churchill had previously been raised, through the interest of James, to a Scotch barony; and when that prince succeeded his brother on the throne, he was further promoted to an English peerage by the style of Baron Churchill of Sandridge. Under this title he contributed by very effectual military service to the suppression of Monmouth's rebellion, and was rewarded with his master's unbounded reliance on his fidelity.

This confidence he basely betrayed, before and after the landing of William of Orange, with a deliberate treachery, which all the sophistry of political and religious party has vainly laboured to justify, and the infamy of which no excuse, even in the difficult circumstances of the times, can be found to palliate. After offering his services to the Prince of Orange, he accepted the command of a large body of James's troops to oppose him; after accepting that command, he deserted to the prince; and when William became king, he received at his hands the title of earl of Marlborough, and the offices of privy-counsellor and lord of the bedchamber, as the reward of his ingratitude. His subsequent conduct throughout the reign of William was consonant to this outset: for he corresponded and intrigued with the exiled king. By this double treason and perjury, he for ever took from the former desertion of his deluded sovereign all extenuation of a conscientious principle; he broke his allegiance to the new king whose favours he had accepted; and he branded his own inconsistency with the meanest motives of self-interest and self-preservation.

William III., who knew equally well how to estimate the capacity and the sincerity of Marlborough, alternately imprisoned and employed, cashiered and re-commissioned, the man whom he is said on his death-bed to have recommended to his successor as the fittest person to 'lead her armies and direct her councils.' The favour of Marlborough's wife with Queen Anne was probably a more powerful, though less rational, motive for the appointment which he now received to the command of the allied forces in the war of the Spanish succession; and he immediately entered on a course of glorious achievement which since the days of Henry V. had never been equalled, and which until our own eventful times was never surpassed by any British commander or army.

When Marlborough landed at the Hague, in June, 1702, to take the command of the allied army, the French under the skilful Boufflers, by the superior force and vigour of their preparations, had already been able everywhere to assume the offensive; the very frontiers of the Seven Provinces were threatened; and it was feared that the efforts of the English general must be restricted to the defence of the republican territory. Moreover, he had to encounter the petty jealousies and disobedience of the other allied commanders, and the opposition of the Dutch deputies, whom the states-general sent into the field to control the movements of their troops, and whose ignorance of war and dread of responsibility were grievous impediments to every bold enterprise. Yet, notwithstanding these obstacles, which shackled all his operations and heavily taxed his forbearance, he succeeded, by a series of masterly movements, in compelling the French armies to retreat in all quarters, delivered the Dutch frontiers from their presence, and closed the campaign by the sieges and capture of Venloo, Ruremond, Stevenswaert, and Liège. These services, short as they fell of the results which might have been attained if the genius of the commander had been allowed its full play, were so far beyond the anticipation of the allies, that the states-general loaded him with eulogy, and Queen Anne elevated him to the ducal title.

The following campaign of 1703 presented a repetition of the same obstacles to the enterprising spirit of Marlborough. Arrested by the timidity of the field-deputies, and harassed by the misconduct of the Dutch generals, he was allowed to effect nothing in the Netherlands except the reduction of Bonn, Huy, Limburg, and Guelders: while the elector of Bavaria with his own troops, and the French under Villars, broke into the Imperial dominions on the Danube, signally defeated the forces of the emperor, alarmed that prince for the safety of his capital, and threatened dissolution to the grand alliance itself. These dangers roused Marlborough to attempt the masterstroke of his military career. Early in the campaign of 1704, after providing for the safety of the Netherlands, he secretly conceived and executed upon his own responsibility the bold design of marching into Germany at the head of the English troops. He formed a junction on the Danube with the Imperialists; stormed the strong Gallo-Bavarian lines at Donauwerth; and finally, in concert with the Imperial commander Prince Eugene of Savoy, a kindred spirit, attacked the enemy on the 13th of August, 1704, at and near the village of Blenheim on the Danube, with such skill and impetuosity as to inflict on them a total defeat. In this memorable battle, the French and Bavarians, who were commanded by the elector in person and Marshals Tallard and Marsin, lost above 30,000 men in killed, wounded, and prisoners, Marshal Tallard himself being among the latter. But the moral and political effects of the victory were yet greater: it dimmed the lustre which the successes of Louis XIV. had shed upon the French arms, and destroyed the charm of their invincibility; it delivered the empire; and it laid Bavaria prostrate before the allies. For this great exploit Marlborough was rewarded with the conveyance to himself and his heirs of the crown lands at Woodstock, on which it was also resolved to erect for him a palace at the royal cost. This noble design to perpetuate the memory of his services was ultimately realised, under the direction of the architect Vanbrugh, in the majestic though cumbrous pile which still bears the title of the castle of Blenheim: but the public enthusiasm which had dictated so splendid a monument was stifled in faction, and the completion of the work is indebted more to the care of his high-spirited widow, than to the good faith of the crown or the munificence of the nation. The gratitude of the Imperial house for the preservation of its capital and dominions was neither less loud nor more durable. The territory of Mindelheim, with the title of prince of the Holy Roman empire, was conferred upon the victor of Blenheim; but though the premature death of his only son left him without heirs male, the dignity was not allowed to descend in the female line; and when the lands of Mindelheim were included in the districts restored to Bavaria at the peace, the Imperial court had the meanness to withhold any compensation from its deliverer.

The march into Germany had liberated Marlborough from the paralyzing control of the Dutch field-deputies and the wretched intrigues of their officers. But his return to the Netherlands subjected him again to the same impediments and annoyances; and in the campaign of 1705, though he skilfully forced the French lines between Namur and Antwerp, he was once more restrained from striking any decisive blow upon the enemy. But in the following year (1706), happily for his wishes, the great efforts of the French in the Low Countries under Villeroy enabled him to tempt them to an encounter; and in the great battle of Ramilies he gained a second victory, so complete that the enemy, with a loss of 13,000 men, eighty standards, and all their cannon, were compelled to evacuate the whole of Spanish Flanders. Brussels, Ghent, Antwerp, and Oudenarde opened their gates to the conqueror, and the strong fortresses of Ostend, Menin, Dendermonde, and Ath were reduced by regular sieges.

Through the apathy of the Dutch these successes were followed, in 1707, by a year of inaction; but in the summer of 1708 an attempt of the enemy to recover possession of Spanish Flanders brought on a general engagement at Oudenarde, which terminated in the utter rout of the French under the dukes of Burgundy and Vendôme, with a loss of 14,000 men. The forcing of the passage of the Schelde and reduction of the great fortress of Lisle, a place of first-rate strength, and defended by a garrison of 15,000 men under Boufflers, were the chief fruits of this victory. The following year (1709) was distinguished by the sanguinary combat of Malplaquet, the most dubious of Marlborough's exploits; since, though he was undoubtedly victorious, the assault of an immense army under Villars in a position of tremendous strength, has exposed him and his colleague Eugene to the charge of reckless temerity; and the result produced no advantages equivalent to the frightful carnage by which it was purchased. The next campaign (of 1710) opened with another successful passage of the enemy's lines by Marlborough, which was followed by the reduction of Douay, Bethune, and other posts. Villars employed the autumn and winter in constructing a series of strong lines on the Flemish frontiers, to cover the interior of France against the further advance of the victorious allies; and so confident was he in the impregnable character of these works, that he openly boasted of having "at last brought Marlborough to his *ne plus ultra*." The fallacy of this vaunt was disgracefully exposed, and never did the military genius of Marlborough break forth with more splendour than in this, which was destined to be his final campaign; even while his mind was distracted, and his energies were crippled by the malignant intrigues of his political enemies in England. On the 5th of August, 1711, by a sudden and unexpected manœuvre, he burst through the lines of his able though gasconading antagonist near Bouchain, formed the siege of that strong fortress, and effected its capture—his last achievement—under the eyes of the superior French army.

The political intrigues which disgraced the court of Queen Anne, and closed the triumphs of Marlborough, belong rather to general history than to the biography of the illustrious leader who was their victim. But they were fomented in his domestic circle; and his imperious wife, if she had assisted his rise, was also the real instrument of his fall. So romantic was the friendship which the queen had cherished for her, that utterly impatient of the etiquette and restraints of a court, and under the assumed name of Mrs. Morley, laying aside every distinction of her rank, she corresponded, in all the freedom and affectionate intimacy of an equal, with the duchess as "her dear Mrs. Freeman." If the duchess had been contented to use her influence with moderation, the easy nature of the queen might never have felt the yoke. But Anne was sincerely attached to Tory principles, the duchess was a violent politician, and notwithstanding her husband's Tory connections and prepossessions, she had become as warmly devoted to the Whig as the queen to the opposite party. As long as William III. lived, an aversion which they shared to that prince and his government, united the two ladies in a bond of political sympathy more powerful than their own differences of opinion. But when his death relieved them from an object of common dislike and apprehension, Anne gave way to her Tory predilections; the duchess ardently advocated the rival cause; and so arrogantly and intemperately were her tyrannical injunctions enforced, that they ceased not until the weak queen had been compelled to surround herself with the leaders of a party whom she detested. Thus goaded and outraged, Anne was gradually alienated from her former friend, whom at last she learned to hate as cordially as she had once loved her; the intriguer Harley, the most perfidious of political adventurers, found it easy to increase the feud; and the machinations of the bedchamber-woman, whom he made his instrument, were sufficient to change the political aspect of Europe.

The hatred of the queen for the duchess was soon unjustly and ungratefully extended to the man who had achieved the principal glories of her reign, and whose great merits were innocent of personal offence. The abject entreaties to which Marlborough descended, to vainly implore the queen to spare his duchess the mortification of a dismissal from her place in the royal household, present the most humiliating scene of his life. The next blow struck by his enemies was his own removal from command; and this measure was envenomed by their malignity with a charge of peculation, which really appears to have been unfounded. Before the storm thus raised against him Marlborough withdrew to the Continent, where he remained until our prospect to the death of Queen Anne. George I., immediately on his accession, restored him to his military offices of captain-general and master of the ordnance; and in the undisturbed enjoyment of these dignities he passed the eight remaining years of his life. In this interval, two paralytic strokes shook his strength, but without at all seriously impairing his faculties; and the line which Johnson inserted in the "Vanity of Human Wishes,"—

"From Marlborough's eyes the streams of dotage flow,"

was at least a poetical exaggeration. For he continued to attend his parliamentary and official duties until a few months before his death, which occurred when he was in the full possession of his senses, and in the seventy-second year of his age, on the 16th of June, 1722. On the death of his son, which happened during the duke's lifetime, the remainder to the ducal title and estate of Blenheim had been settled on his daughters and their heirs male; and the eldest, who thus succeeded her father, having died leaving no son, the family honours descended through her next sister, the lady of Charles Spencer, earl of Sunderland, to the house which still inherits them, and which, in our own age, has assumed the name of Churchill.

In estimating the character of Marlborough under its twofold aspect of political and military greatness, it will readily be concluded that he was the most distinguished personage of his country and times. As a statesman, he was unrivalled in personal address and diplomatic skill, in the arts of persuasion, and in the powers of combination and arrangement. He was the life and soul of the grand alliance which arrested the ambitious career of Louis XIV. and preserved the liberties of Europe; his influence pervaded every continental court; and by his energetic hand was set in motion every spring of that vast confederacy, which centred its only real point of confidence in his spirit. One of his bitterest enemies and ablest contemporaries, Bolingbroke, was not ashamed to acknowledge, after the grave had closed over him, that he was the greatest minister that this country had ever possessed.

As a general, it has not been the fate of Marlborough to be numbered with the few, such as Maurice of Nassau, Gustavus Adolphus, or Frederic of Prussia, whose genius has stamped its impress upon the warfare of their times, and made a distinct epoch in military science. He left the art, which he practised with unrivalled ability, in the same state in which he had found it; nor is there a single change or improvement in strategy attributed to his master mind. But if this absence of inventive power may seem to detract from his claim to the very highest order of military merit, it must not the less be remembered that he was beyond comparison the most accomplished commander of his warlike age. It was an age of formal tactics and deliberate sieges; which had produced Vauban and Coehorn, raised the art of fortifying for the time to an apparent perfection, and exaggerated the importance of regular fortresses and long-drawn lines of intrenchment. In the system of operations which naturally grew out of such circumstances, Marlborough greatly excelled; and of six conspicuous occasions on which he is recorded to have penetrated the intrenched positions of his opponents, five were nearly bloodless triumphs of his tactical skill. In all these, his success equally proclaims his own superiority over his antagonists, and the vicious practice of the age, which, in attempting to cover an assailable country with extended chains of intrenchment, laboriously invited as many points of attack as it multiplied works. But Marlborough himself, in his own practice, adhered to the same rules of defence, of which his success might have shown him the futility. Once indeed, after the victory of Oudenarde, he broke through the pedantry of rules, and proposed to Eugene, by masking Lisle and Tournay with a corps of observation, to penetrate into the heart of France; a plan which, instead of consuming the remainder of a victorious campaign in the siege of two fortresses, might have triumphantly ended the war. But the bold proposal seemed too hazardous even to Eugene.

Each however of Marlborough's great battles, and of the operations which preceded them, will testify that his skill comprehended much more than the conduct of a war of sieges and intrenchments. The consummate adroitness with which the objects of his memorable march into Germany in 1704 were concealed from the enemy, and their fears successively misdirected to the Moselle, to Alsace, and to Landau, until it was too late to prevent his real designs on the Danube, must ever be numbered among the most perfect efforts of military science. So also may be cited, with equal admiration, the singular and beautiful manœuvres by which the battle of Ramilies was won, and of which the curious military reader may find an ample and lucid account in the memoirs of General Kane, himself an eye-witness and an excellent tactician. And when it is considered that the successes of Marlborough were gained with an army in which the native British contingent never amounted to 20,000 men, and of which three-fourths were composed of a motley roll of Dutchmen, Hanoverians, and

Hessians, Danes, Wirtembergers, and Prussians, and moreover that his plans were in almost every enterprise marred by the timidity or obstinacy of the Dutch deputies, the moral triumphs of victory with such heterogeneous materials, and under such heavy disadvantages and discouragements, must very much raise our estimate of the genius by which they were won.

As a man, it is less easy to form a true judgment of the character of Marlborough than as a statesman or a general. If we were to estimate his moral worth by his double treachery to James II. and to William III., by his tame submission to the ingratitude of Queen Anne, and by the avarice which degraded his private habits, he might justly be numbered among the greatest and meanest of mankind. Nor is there any weight in the extenuation which has been attempted for his political falsehood, that he was no worse than his contemporaries; since it is the test of true greatness to rise above, not to sink to, the level of a common corruption. Yet with all his faults, it would be easy to prove that there were not wanting in Marlborough many of the qualities of a good patriot and a good man. His friend the lord treasurer Godolphin and himself appear, of all their contemporaries, to have been most free from the virulent spirit of faction and most sincerely devoted to the true honour and interests of their country. The attachment of Marlborough to the tenets and principles of the Church of England was sincere and pure; he was unaffectedly a person of strong religious feeling and practice; and in these respects the example which, as a commander, he held out to his troops, and enforced in his camp, of a piety without fanaticism, was as salutary as it has been infrequent. His courage too, which the inconceivable baseness of faction affected to doubt, and which in his youth had been fiery and impetuous, displayed in his later years the calm and collected spirit of the Christian hero. In public action he was ever as humane and merciful, as towards personal enemies he was placable and magnanimous. In private life, if we except the stain of parsimony, his conduct, at least after his marriage, was a pattern of moral virtue; his temper was imperturbably sweet, gentle, and affectionate; and he was but too fond a husband, too confiding a friend, and too indulgent a master.

The principal biographies of Marlborough and memoirs relating to his campaigns are:—1, Lediard's Life of him (3 vols. 8vo., London, 1736). 2, An anonymous Life, published in 8vo. in 1713, and accompanied by a Life of Prince Eugene, evidently written by one who had served under the duke and shared his confidence. 3, Dumont and Rousset, 'The Military History of Prince Eugene of Savoy, the Duke of Marlborough,' &c. (translated from the French by P. Chamberlen, folio, London, 1736). 4, 'Histoire de Jean Churchill, duc de Marlborough' (3 vols. 8vo., Paris, 1808): a signal foreign tribute to his greatness, since it was composed by order of Bonaparte, and written, with a few exceptions, in a fair and candid spirit. 5, Coxe's 'Memoirs of John, duke of Marlborough' (3 vols. 4to., London, 1818-19):—a work of which the chief value consists in a great mass of original correspondence, published from the family papers at Blenheim and other sources. 6, Brodrick's 'Complete History of the late War in the Netherlands' (8vo., London, 1713). 7, Kane's 'Campaigns of King William and Queen Anne, from 1689 to 1712,' &c. (8vo., London, 1745). 8, Millner's 'Journal of all the Marches, Battles, Sieges, &c. of the Confederate High Allies, from 1701 to 1712, under the conduct and command of the Duke of Marlborough' (8vo., London, 1733).

MARLOW, GREAT, a market-town, parliamentary borough, and parish, in the county of Bucks and hundred of Desborough. The situation of the town, on the left bank of the Thames, is pleasant and picturesque. Its direct distance from Buckingham is 30 miles south by east, and from London about 29 miles west by north. There are two principal streets, in the form of a T, and three smaller ones. The parish church, dedicated to All Saints, is a handsome modern structure, which was consecrated in 1835, and is surmounted by a spire. A suspension bridge was erected over the Thames in 1835; its span from pier to pier is 75 yards. The living, a vicarage in the diocese of Lincoln and patronage of the dean and chapter of Gloucester, produces a net income of 172*l*. In the year 1628 Sir William Borlase founded a school here for the education of poor boys. The number of scholars in 1833 was twenty-four, and the subjects then taught were reading, writing, and arithmetic. The income of the charity at the latter date was 118*l*. 12*s*. 10*d*., out of which the schoolmaster received a salary of 50*l*. A portion of the remaining income has been appropriated since 1822 to the payment of a schoolmistress, who teaches twelve poor girls to read, make lace, and do plain work. Besides the above there is a national school, supported by voluntary donations, for educating children of both sexes; there are also the Oxford Lane almshouses, and several other benevolent foundations of minor importance. (See the *Further Report of the Commissioners on Charities*, pp. 133-145.) The borough has returned two members to parliament since the reign of Edward I. Its population in 1831 was 4237.

(Langley's *History of the Hundred of Desborough and Deanery of Wycombe*, Lond., 1797, 4to.; *Parliamentary Papers*, &c.)

MARLOWE, CHRISTOPHER, a dramatic writer of some eminence, was born, according to Malone, in 1564, but the exact date is unknown. All that is known of his life may be given in a very few lines. He was entered of Corpus Christi College, Cambridge, took his bachelor of arts' degree in 1583, and that of master of arts in 1587. On leaving the university he became a playwright, and perhaps an actor. His moral character appears to have been bad. He was killed in a quarrel of a disgraceful nature, June 1st, 1593, as appears from the register of the old church at Deptford, from Anthony à Wood, and others.

The following plays are attributed to him:—'Dr. Faustus,' 'Edward the Second,' 'The Jew of Malta,' 'Tamburlaine the Great,' 'Lust's Dominion,' 'The Massacre at Paris,' and 'Dido, Queen of Carthage.' The prevailing opinion however is that the three first only are his sole productions.

Both the matter and the style of 'Tamburlaine' are asserted to differ materially from Marlowe's other compositions, and there is reason to believe that 'Lust's Dominion' is later than his time.

There remain, then, 'The Massacre of Paris,' 'The Jew of Malta,' 'Edward the Second,' and 'Faustus.' Of the first little need be said; for the text, as it now stands, is an imperfect copy of a hasty work, as Collier has very well shown by a comparison of the received version with one leaf of a contemporary MS.

'The Jew of Malta' is one of those extraordinary impersonations which imply in the chief character a villainy more than human; such, in fact, as was ascribed only to the nation to whom Barabas belongs. There is a general resemblance between Barabas, the 'Jew's dochter,' in the old ballad, and Shylock; but they are like, not as imitations of each other, but as representations of one class, supposed to contain in itself malignity and avarice, and cruelty beyond all comparison.

'Faustus,' which succeeded 'The Jew of Malta,' is a play to which greater interest is attached at present than fifty years ago, owing to the celebrity of Goethe's 'Faust.'

Those who consider that the 'Faust' of Germany is the greatest conception of human invention—who believe that a deep meaning lies hid behind all the apparent absurdities, and that the moral influence of the work is of a high and impressive kind—will of course laugh at any attempt at comparing the German with his English predecessor. At the same time they must allow that Marlowe's play is one of the first, if not the very first attempt at portraying the struggles of a man whose faith is wavering, the first exhibition in a dramatic shape of that doubting spirit which has been on the ascendant for the last four centuries. Moreover the solitary horror of Faust's death far surpasses the stage-effects which tell so strongly in the last scene of the first part of the German poem; and it would not be hard to show that Goethe has borrowed not a little from his English rival.

Perhaps, on the whole, we must assign the first place among Marlowe's works to 'Edward the Second.' It is the prelude to the Shaksperian 'History,' and contains many passages which almost come up to Shakspere's manner. Those who wish to pursue the subject at greater length may consult an interesting article in the 'Quarterly Review,' which adds much to our information on the subject of the English drama.

Owing to the carelessness of the printers, many lines have been confused in Marlowe's plays, to the grievous injury of various passages, which now appear to be prose, though they are in reality verse.

Marlowe has been compared to Æschylus: there is something specious in the comparison, but it can only be very general. To him we are indebted for the first regular form of the English drama cleared of rhymes; and he may be considered as the link between Shakspere and the Moralities. 'Faustus' is nearly a 'morality;' 'Edward the Second' is a regularly formed 'history.'

Besides his plays Marlowe translated Ovid's 'Art of Love' and some other classical works.

(Collier's *History of Dramatic Poetry*; Preface to Marlowe's Works, ed. 1826; and *Quarterly Review*.)

MARLSTONE. Sandy, calcareous, and irony strata, which divide the upper from the lower lias clays, are thus designated. (GEOLOGY.) This mass of rocks is nowhere so well developed as in Yorkshire and Leicestershire.

MARLY. [SEINE ET OISE.]

MARMALADE, a sort of preserve, made with sugar and the Seville or bitter orange, a variety of the fruit of the Citrus Bigaradia. It is more wholesome when properly made, *i.e.* when the rind is soft, than most other sweet preserves, as the bitter communicates tonic and stomachic properties to it.

MARMANDE. [LOT ET GARONNE.]

MARMONTEL, JEAN FRANÇOIS, was born at Bort in Limousin, in 1723. His parents were of very humble condition, and he owed his instruction in the Latin tongue to the gratuitous tuition which he received in a college under the direction of the Jesuits. His father placed him with a tradesman at Clermont, but a love for literature interfered with all commercial pursuits. At an early age he became professor of philosophy at a seminary of the Bernardins at Toulouse, and supported his mother and family after the death of his father. An acquaintance with Voltaire, to whom he had sent some poems, and who encouraged his attempts, brought him to Paris in 1745. Voltaire introduced him to several persons of distinction, and the success of his first tragedy, 'Denys le Tyran,' stamped him as a dramatic poet. Owing to the patronage of Madame Pompadour he was made historiographer of the royal buildings (*Historiographe des Bâtimens du Roi*), with a pension of 1500 livres, and he also obtained the right of publishing the 'Mercure,' by which he gained 40,000 livres. He was falsely suspected of satirising a person of distinction, and in consequence lost the 'Mercure,' and was confined in the Bastile. His celebrated *Contes Moraux*—which, however dubious as to their moral character, are exquisite specimens of the lighter kind of French writing—followed his release, and gained him great reputation. On the death of Duclos he became Historiographer of France; and in 1783 he was made secretary to the Académie in the place of D'Alembert. He lost his appointments and his property on the breaking out of the Revolution, and he removed some distance from Paris in a state of destitution. In 1796 he became member of the National Institute, and in 1797 was elected into the council of the antients, but this election having been reversed after the 18th Fructidor (Sept. 4) in the same year, he retired to Abbeville, where he died in obscurity in 1799, and was buried in his own garden by Catholic priests.

The works by which Marmontel is chiefly known are his *Contes Moraux*, his romances 'Belisaire' and 'Les Incas,' and his 'Mémoires.' The 'Contes Moraux' and 'Belisaire' are so familiar in an English shape, that they are almost British classics.

MA'RMORA, or MARMARA, SEA OF, the *Propontis* of the antients, is situated between the Grecian Archipelago and the Black Sea, communicating with the former by the Dardanelles, the antient Hellespont, and with the latter by the strait of Constantinople, the antient Bosporus. Towards the east it terminates in the long and narrow gulf of Ismid, and towards the south-east in the gulf of Modanieh. These were respectively the Astacenus or Olbianus Sinus (after the Gulf of Nicomedia) and the Cianus Sinus of the antients.

The early Greek geographers, more especially those before the time of Ptolemy, appear to have been very much mistaken respecting the general position of this sea. They represent its greatest length in a direction nearly north and south, instead of east and west, placing the Thracian Bosporus and the Hellespont on the same meridian. Eratosthenes however is thought to have possessed the requisite data for determining its great inclination from the west towards the east, having described the parallel of Amisus as passing through the Propontis and the Hellespont; and the reason assigned for his making no use of this knowledge is his unwillingness to depart from the prevailing opinion of the age in which he lived. Polybius also seems to have been aware of the inclination of the Propontis to the east.

Herodotus gives the length of the Propontis at 1400 stadia, and its breadth at 500 (iv., 85): he allows 400 stadia as the length of the Hellespont (Dardanelles). Strabo (p. 125, Casaub.) gives 1500 stadia as the length of the Propontis from Byzantium to the Troad, and reckons its breadth nearly the same. He also adopts the opinion of Pytheas as to its direction, placing the Hellespont and the Bosporus under the same meridian, and it is not until the time of Ptolemy that we find the Propontis beginning to assume an inclination from west to east, and even then the error in its position received but a slight correction.

Turning to our modern maps, the Sea of Marmora is comprehended between the parallels of 40° 16′ and 41° 5′ N. lat., and the meridians of 26° 40′ and 30° 5′ E. long. Its extreme length, from west to east, including the gulf of Ismid, is about 160 geographic miles; from strait to strait, in a west-south-west and east-north-east direction, 110 miles; and its greatest breadth is 43 miles.

Its shores are described by modern travellers as highly cultivated and picturesque, with a greater boldness of character on the Asiatic than on the European side.

The depth of this sea is in many parts very considerable. In the Admiralty Chart published in 1833 we find 133 fathoms about five miles north-east of Marmora Island, and about the same distance due north of it no bottom at 355 fathoms; from which we may infer that the depth is very much greater midway between the two shores.

Since there are no regular tides in the eastern basin of the Mediterranean nor in the Black Sea, they are much less to be expected in the Sea of Marmora. We accordingly find that there is no periodical ebb and flow of its waters; but a current sets through it from the Bosporus, varying its velocity according to the season and the prevailing winds, and continuing its course through the Dardanelles to the Archipelago. Its navigation is by no means difficult; it is generally free from dangers, and good anchorage may be found all along its northern shore, under its various islands, and inside the peninsula of Artaki.

The most remarkable islands in this sea are, Marmora (from which the sea takes its name), Rabi, and Liman-Pasha, occupying its western division; Papa, or Kalolimno, off the gulf of Modanieh; and the group called the Princes Islands, near the Asiatic shore, about ten miles south-east of Constantinople. The Princes Islands are nine in number, two of which, Oxeia and Rata, are uninhabited. Of the others, Prinkipos (the antient Pityusa) and Kalki (the antient Chalcitis) were once distinguished for their copper-mines. Their scenery is described as being very beautiful, and the Frank merchants of Pera and others have their summer residences on them.

The remarkable peninsula of Artaki was formerly an island, on which stood the once flourishing city of Cyzicus, the ruins of which are still to be seen, and which confirm the historical testimony of its opulence. The modern town of Artaki, which gives its name to the peninsula, and which is thought to occupy the site of the antient Artace, is not a town of much note. It is said to contain about 4000 inhabitants, and has some trade in wine, oil, and silk.

In addition to Constantinople, at the entrance of the Bosporus, and Gallipoli, at the entrance of the Dardanelles, the principal towns of the Sea of Marmora are, Rodosto, Erekli, and Silivri, on the northern, and Kemeris, Karabouga, Panurma, and Modanieh, on the southern, shore. There is also Ismid, at the head of the gulf of that name, and Gumehlek, at the head of the gulf of Modanieh. The chief rivers which enter this sea are the Tchorlu and the Istidji, in Europe, and the Ustvola (the antient Granicus), the Bokir, or Satalderé (the antient Æsepus), and the Mualitch (the antient Rhyndacus), in Asia. There are two other rivers on the European side which appear to be of some importance; they are called Karasodere and Tuzlidere in the large map of European Turkey, Vienna, 1829.

MARMORA, or MARMARA (the antient Proconnesus), is an island in the sea above described. It was early celebrated for its marble quarries, from which Cyzicus and other neighbouring cities were supplied with materials for their edifices. (Strabo, p. 588.) More recently Constantinople has been indebted to these quarries for the embellishment of its mosques, fountains, and other public buildings; but the marble is now principally used for the sepulchral monuments of the Turks and Armenians. It is said to have abounded with deer, from which circumstance the Greek names Proconnesus and its earlier appellation Elaphonnesus are said to be derived.

It has a mountainous range of moderate height, has rather a sterile aspect, and is poorly inhabited. The chief town, which is also called Marmora, is situated on its south-west side, and is built of wood. The island has several villages, and its inhabitants are chiefly Greek Christians.

MARMORA, a town of Asiatic Turkey, in the province of Anatolia, in 28° 43′ N. lat. and 28° 5′ E. long.

MARMOT. [MURIDÆ.]

MARNE, a river in France belonging to the system of the Seine, which it joins just above Paris. [SEINE.]

MARNE, a department of France, bounded on the north by the department of Ardennes, on the east by that of Meuse, on the south-east by that of Haute Marne, on the south by that of Aube, on the south-west by that of Seine et Marne, and on the west and north-west by that of Aisne. Its form is irregular. The greatest length is from north-west to south-east, from the neighbourhood of Fismes on the Vesle to the neighbourhood of St. Dizier (Haute Marne) on the Marne, 74 miles; its greatest breadth, at right angles to the length, is from the village of Petit St. Hilaire on the Suippe to the bank of the Seine, near the junction of the Aube, 62 miles; the area is estimated at 3158 square miles, an area exceeding that of any English county except Yorkshire, and exceeding by above 100 square miles that of the two counties of Essex and Suffolk. The population, in 1831, was 337,076; in 1836, 345,245, showing an increase in five years of 8169, or about 2·5 per cent., and giving 109 inhabitants to a square mile. In amount of population it is very far below the two English counties with which we have compared it, not very much indeed surpassing the single county of Essex, the more populous of the two. In density of population it is far below the average of France, and below every English county except Westmoreland. Châlons sur Marne, the capital, is in 48° 57′ N. lat. and 4° 21′ E. long., 89 miles in a direct line east of Paris, or 102 miles by the road through Meaux, Château-Thierri, and Epernay.

The department consists of extensive plains, or of undulating or hilly tracts, in which the greatest elevations do not exceed 1200 feet above the level of the sea. The general inclination of the surface is toward the west and north-west, in which directions the waters flow. The western side of the department is occupied by the supracretaceous formations of the Paris basin, and the rest of the department by the chalk itself, except just along the eastern border, where the formations that underlie the chalk crop out. The mineral treasures consist in quarries of freestone for building, and of stone from which the best millstones in Europe are made, fine sand in much request for glass-works, and potters' earth. Peat is dug in considerable quantity, especially in the valley of the Vesle; about 1000 tons of potters' earth are sent yearly to Paris, or into the departments of Meurthe and Aisne. The millstones of this department are sent into the east and south of France, and even into Germany. About 1000 tons of rough chalk and 1500 tons of refined chalk are sent yearly to Paris, or into Lorraine, Alsace, and Germany. Near Vitry is a bed of considerable thickness of sulphureous ashes, which however are not wrought, at least to any extent. There are several mineral springs: those of Sermaize on the Saulx, near the eastern boundary of the department, are in the highest repute.

The rivers all belong to the system of the Seine, in the basin of which the whole department is included. An arm of the Seine, called the 'Canal Sauvage,' and the main stream of the river itself, just touch the southern border of the department, which they separate for seven or eight miles from the department of Aube. The Aube has a small part of its course in this department, on the border of which it joins the Seine. The Auges joins the Aube. The Marne enters this department in the south-east, from the department of Haute Marne, and flows through it in a channel the direction of which bends gradually from north-west to west. It receives on its right bank the Orne or Ornain (into which fall the Saulx and the Chée), and several other smaller streams. The Morin, the Petit Morin, and the Melun or Sumerlin rise in this department, but join the Marne beyond the boundary. The rivers in the north and north-east are the Aisne, a principal feeder of the Oise, and the Suippe and the Vesle, feeders of the Aisne. The inland navigation of the department is thus [illegible] in the government returns:—Seine, 3 miles; Aube, 9 miles; Marne, 102 miles: total, 114. None of the other rivers are navigable, and there are no canals.

The number of government roads is eight: they had (in Jan., 1837) an aggregate length of 364 miles, viz. 238 miles in repair, 99 out of repair, and 27 unfinished. The principal road is that from Paris, by Dormans and Epernay, to Châlons, from which place one branch runs by Ste. Ménéhould to Verdun and Metz, and from thence to Mayence or Mentz, and Frankfort in Germany; the other to Vitry, Bar le Duc, Nancy, and Strasbourg. The great road from Paris to Mezières, and so to Namur and Liège in Belgium, passes through Fismes and Reims. Another road from Paris to Châlons branches off from the great road at La Ferté-sous-Jouarre (Seine et Marne), and passes through Montmirail; and a road from Paris to Vitry passes through Coulommiers (Seine et Marne) and Sezanne. Roads from Châlons lead to Reims and Laon (Aisne), and to Arcis-sur-Aube and Troyes (Aube); and a road from Reims leads by Epernay and Sezanne to Nogent-sur-Seine (Aube). The departmental roads were fifteen in number (Jan., 1837), and had an aggregate length of 289 miles, viz. 113 in repair, 50 out of repair, and 126 unfinished. The bye-roads and paths amounted to above five thousand.

The soil of the department varies greatly: nearly two-thirds consist of chalky plains covered with a thin layer of vegetable, often sandy, soil, producing good crops of grain, but scarcely admitting the growth of trees, except Scotch firs, and other trees of similar kind, which have lately been planted to a great extent. In the southern parts of the department these chalky plains are so desolate as to have incurred in former times the reproachful epithet of 'Champagne Pouilleuse.' The kinds of grain chiefly cultivated are wheat, barley, and oats (in all of which the produce is considerably above the average of France), and especially rye and maslin, or mixed corn. Vegetables, fruit of excellent quality (especially the melons of Châlons), and mushrooms, are grown; flax, hemp, and oleaginous plants are pretty generally cultivated, and the osier-beds are extensive. About 250 tons weight of rape, linseed, or other vegetable oils are sent yearly from Châlons to Paris, Lyon, and Reims. Champagne wine is however the staple production of the department: it is distinguished as *vin de rivière* (wine of the river), and *vin de montagne* (wine of the hills), the first growing on or near the banks of the Marne, and being chiefly white—the second at a distance from that river, and being chiefly red. The vineyards occupy an extent of from 45,000 to 50,000 acres: the wines are sparkling or creaming, and still. The proportion of sparkling or creaming wine has much increased of late years. The best growths of the vin de rivière are from the right bank of the Marne in the neighbourhood of Epernay. Of these the wines of Ay, Mareuil, and Hauvilliers have the highest reputation. The best vin de montagne are the white wines of Sillery, and the red wines of Ambouay, Verzy, Verzenay, and other places in the arrondissement of Reims. About three-fourths of the sparkling and creaming wines of Champagne are exported to Italy, Switzerland, Germany, Poland, Russia, and England. The red wines are sent to Paris, and into the departments of Somme, Aisne, Ardennes, and Nord. The woodlands are extensive: the chief trees are the oak, the birch, and the various species of pine and fir. Charcoal is made near Sainte Ménéhould, and sent to Paris.

The meadow and pasture lands occupy 95,000 to 100,000 acres. A great number of horses are bred, but the quantity of horned cattle is below the average of France. There are numerous flocks of sheep of various breeds, merinos, English and native; and the Tibet goat has been introduced of late years. The quantity of wool grown is below the average of the departments of France. Bees are numerous; and the streams and ponds of the department abound with fish.

The department is divided into five arrondissements, as follows:—

Name.	Situation.	Area in Sq. Miles.	Population in 1831.	Population in 1836.	Communes.
Châlons	Central	627	48,099	48,535	109
Epernay	S.W.	818	83,278	86,452	185
Reims	N.W.	685	120,680	123,919	181
Ste. Ménéhould	N.E.	428	34,952	35,812	82
Vitry	S.E.	600	50,067	50,527	133
		3158	337,076	345,245	690

There are thirty-two cantons or districts, each under a justice of the peace.

In the arrondissement of Châlons are Châlons-sur-Marne (pop. in 1831, 12,413; in 1836, 12,952), [Châlons], on the Marne; and Suippe or Suippes (pop. 2333), on the Suippe. The long village of Courtisols, or Courtison, on the road from Châlons to Ste. Ménéhould, consists in fact of three villages, forming two parallel streets or roads, and extending in all about five or six miles. They have about 2000 inhabitants, distinguished from the surrounding population by their peculiar dialect, customs, and agricultural skill, circumstances which have been the subject of much antiquarian conjecture. Near the village are the traces of a Roman road and of the camp of Attila.

In the arrondissement of Epernay are Epernay (pop. in 1831, 5214; in 1836, 5457), [Epernay]; Damery and Dormans, on the Marne; Orbais, on the Surmelin; Montmirail (pop. about 2000), on the Petit Morin; Sézanne and Courgivaux, near the Morin; Anglure, on the Aube; Fère Champenoise (pop. 2049), on a branch of the Auges; Barbonne, Vertus, Avize, and St. Martin d'Ablois. Damery is in a district producing excellent wine. The inhabitants carry on a considerable trade; oats, timber, and charcoal are sent down the Marne to Paris and Meaux, and gypsum is brought up that river from Château-Thierry. Spinning and weaving are carried on, and tiles and pottery of good quality are made near Dormans, which is also the mart for linens made in the neighbourhood. Montmirail was the scene of one of Bonaparte's victories over the allies in the hard-fought campaign of 1814. Millstones are quarried in the neighbourhood. Sézanne (pop. above 4000 in 1827) was once a place of greater consequence. It was taken by the English, destroyed by the Protestants under Charles IX., and consumed by fire in 1632. It is now the seat of considerable trade in agricultural produce. At St. Martin d'Ablois millstones of inferior quality are produced, and paper and cardboard or pasteboard manufactured. Vertus and Avize are in the midst of vineyards, which produce excellent wine. Fère Champenoise suffered much in the campaign of 1814.

In the arrondissement of Reims are Reims (pop. in 1831, 35,971; in 1836, 38,359), [Reims], and Fismes (pop. 1969 town, 2119 whole commune), on the Vesle; Cormicy, in the country north of that river; and Mareuil, Ay (pop. about 2500), Avenay, and Châtillon sur Marne, on or near the Marne. Fismes was the birth-place of Velly, one of the best of the French historians; the inhabitants manufacture coarse woollens. Ay and Mareuil are surrounded by vineyards, producing some of the best wine in the department.

In the arrondissement of Ste. Ménéhould are Ste. Ménéhould (pop. in 1836, 3762 for the commune), and Vienne le Château, on or near the Aisne. The former is a regularly built town, with houses of brick and stone, and a town-hall of elegant architecture. The manufactures of the town, pottery, glass, and leather, are inconsiderable; but a good deal of fruit is grown in the country round. Ste. Ménéhould was the first place besieged by Louis XIV., who entered it through the breach. Louis XVI. was recognised here in attempting to escape from France.

In the arrondissement of Vitry are Vitry (pop. in 1831, 6976; in 1836, 6822), on the Marne; and Heiltz-le-Maurup and Sermaize (pop. 1790), on or near the Orne, or Ornain. Vitry arose from the ruins of another town of the same name in the immediate neighbourhood, now a village distinguished as Vitry-le-Brûlé. This ancient Vitry was taken by Louis VII. le Jeune, from Thibaud, count of Champagne; and as he scrupled to stain the church with the blood of thirteen hundred people who had taken refuge in it, he ordered the edifice to be set on fire, and the unhappy fugitives to be burnt alive. From this detestable act the place acquired its surname 'le brûlé,' or 'the burnt.' The ill-fated town was subsequently burnt by Jean of Luxembourg, and entirely ruined by the army of the emperor Charles V. After this last catastrophe Francis I. determined to rebuild it, but not on the same site. The new town, distinguished by the name of Vitry-le-François (not le Français), or Vitry-sur-Marne, rose on the bank of the Marne. It has broad and straight streets; and the houses, though built of wood, are respectable. It was intended to fortify the town, but it has never had any better defence than an earthen rampart and a ditch. There are a considerable number of manufactories of hats, cotton yarn, and cotton hose. There are also some oil-presses. There are extensive nursery-grounds round the town, and in the arrondissement strong hemp is grown, which is sent to Paris and the department of Seine Inférieure by the Aube and Marne. Sermaize has mineral springs, which are in tolerable repute.

The population, when not otherwise specified, is that of the commune, and is chiefly taken from the returns of 1831.

The manufacturing industry of the department is considerable. Wool-combing or carding, spinning, weaving, dyeing, and the other processes connected with the manufacture of woollen cloths, kerseymeres, flannels, blankets, merinos, shawls, and other woollen goods, and some cotton goods, are carried on to a considerable extent in the districts of which Reims is the centre. Many of these processes are carried on by the workmen and their families on their own account. It is not many years since the factory system was introduced at Reims; before that, the same room served for the dwelling-place and workshop of the manufacturer. Some linens and silks are made; also leather, earthenware, wax candles, soap, cutlery, hats, and paper. The exports, both of agricultural produce, especially corn, wine, and oil, and of manufactured goods, are considerable. They are sent down the Marne from Vitry, Châlons, Epernay, and Dormans.

The department of Marne is divided between the diocese of Châlons, which comprehends the arrondissements of Châlons, Epernay, Vitry, and Ste. Ménéhould; and the archdiocese of Reims, which comprehends the arrondissement of Reims, with the adjacent department of Ardennes. The bishop of Châlons is a suffragan of the archbishop of Reims. The department is included in the jurisdiction of the Cour Royale and the circuit of the Académie Universitaire of Paris. It is included in the second military division, of which the head-quarters are at Châlons. It returns six members to the Chamber of Deputies.

The state of education in this department is considerably above the average of France; it ranks as the tenth department in this respect. The number of those enrolled in the military census of 1828-9 who could read and write was sixty-three in every hundred, the average of France being thirty-nine.

This department was comprehended at the time of Cæsar's invasion of Gaul in the territories of the Suessiones, or Suessones (Σουεσσίωνες and Σουέσσωνες, Strabo), the Remi (Ῥῆμοι, Ptol. and Strabo), and the Catalauni, confederated Belgic tribes; and of the Tricasses, a Celtic people. In the Roman division of the country the Belgic tribes were comprehended in the province of Belgica Secunda; the Tricasses in that of Lugdunensis Quarta or Senonia. Several Gallic or Roman towns were included in its limits; as Durocortorum, capital of the Remi, afterwards called Remi, now Reims; Basilia, perhaps Baconne, between the Vesle and the Suippe, in the territory of the same people; Fines, now Fismes, on the frontier between the Remi and the Suessiones; Duro Catalaunum, capital of the Catalauni, afterwards called Catalauni, and now Châlons; Fanum Minervæ, near La Cheppe, on a feeder of the Vesle, and Ariola, now Vroil, near the Ornain, in the territory of the same people; and Bibe, perhaps St. Martin d'Ablois, in the territory either of the Catalauni or the Suessiones. In the downfal of the Roman empire this department was the scene of contest between Ætius, the Roman general, with his allies, the Franks, Burgundians, and Visigoths; and Attila, king of the Huns, with his allies, the Alans, the Gepidæ, and the Ostrogoths. The defeat of Attila at Châlons led to the evacuation of Gaul by him. Subsequently the department became subject to the Franks of Austrasia, and in the feudal ages formed part of the county of Champagne, which came, in 1335, into the hands of Philippe VI. de Valois, and in A.D. 1361 was formally united to the French crown by Jean II. In the campaign of 1792 this part of France was the scene of contest between the Austrian and Prussian forces under the duke of Brunswick, and the French under Dumouriez and Kellermann; and in the campaign of 1814, between the Russian and Prussian forces under Blucher, and the French under Napoleon and his generals.

MARNE, HAUTE, a department in the north-eastern part of France. It is bounded on the north-east by the department of Meuse, on the east by that of Vosges, on the south-east by that of Haute Saône, on the south-west by that of Côte d'Or, on the west by that of Aube, and on the north-west by that of Marne. Its form approximates to an oval, having its greatest length from north-north-west, near St. Dizier, to south-south-east in the neighbourhood of Fay-le-Billot, 80 miles; and its greatest breadth, at right angles to the length, from the neighbourhood of La Ferté-sur-Aube to that of Bourmont, on the Meuse, 48 miles. Its area is estimated at 2420 square miles, which is rather less than that of the English county of Devon, or rather more than the conjoint area of the two counties of Wilts and Dorset. The population, in 1831, was 249,827; in 1836 it was 255,969, showing an increase in five years of 6142, or about 2·5 per cent., and giving about 106 inhabitants to a square mile. In amount of population and in density of population it is to the average of the French departments in the proportion of 2 to 3, and falls very far below the English counties with which we have compared it. Chaumont, the capital, is in 48° 7′ N. lat. and 5° 9′ E. long., 135 miles in a direct line east-south-east of Paris, or 148 miles by the road through Provins, Troyes, and Bar-sur-Aube.

The department is hilly, and even mountainous in the southern and eastern parts. The heights of Langres and the Faucilles mountains, which constitute a continuous range, and form part of the chain that unites the Cévennes with the Vosges, cross the department in a north-eastern direction near the south-eastern boundary. Lateral branches from this main range run to the north-west, separating the valleys watered by small streams belonging to the system of the Seine; and near the eastern extremity of the department a more important lateral branch runs in a northern direction, separating the basin of the Meuse from that of the Seine. The summits of the main ridge are not very lofty, scarcely rising in any instance to more than 1600 feet. The strata which intervene between the chalk and the saliferous sandstone occupy the whole of the department. The mineral treasures are, iron in abundance in the centre and northern parts; freestone, which bears a fine polish, whetstones, gypsum, brick earth, fullers' earth, and marl. There are many turf-pits, and several mineral springs, of which those of Bourbonne-les-Bains are in the highest repute. The heights of Langres with the Faucilles, and the principal lateral branch from them, divide the department between the three great slopes, the Western or oceanic, the Rhenish, and the Mediterranean. [FRANCE.] The central, northern, and western parts belong to the oceanic slope, and are included in the basin of the Seine. Most of the streams which water this part rise on the north-western slope of the heights of Langres, and have a north-western course. The source of the Ource, one of the earlier feeders of the Seine, is just within the western boundary; next to it are those of the Aube, and its feeder the Aujon; and then those of the Marne with its feeders, the Sure, the Treyre, and the Rognon. The Marne, the most important of these streams, flows through the department in nearly its whole length, receiving by the way the above-mentioned tributaries, and becoming navigable just before it quits the department. The Blaise, another tributary of the Marne, rises at the foot of the heights of Langres, and waters the western side of the department, but does not join the Marne within the boundary. The Voire, a tributary of the Aube, waters the north-western parts. The eastern side of the department belongs to the Rhenish slope, and is comprehended in the basin of the Meuse, which has its source and a small part of its course within the boundary. The south-eastern part belongs to the Mediterranean slope, and is comprehended in the basin of the Rhône. It is watered by the Vingeane, the Saulon, and the Amance, feeders of the Saône, which rise on the south-eastern slope of the heights of Langres. There are few lakes or pools: the only marshes are in some parts of the valleys of the Meuse and the Amance. The only inland navigation is that of the Marne, about seven or eight miles long.

There are only six Routes Royales, or government roads, having an aggregate length of 253 miles; viz. 174 in repair, 78 miles out of repair, and 1 mile unfinished. The principal road is that from Paris to Bâle, which enters the department on the west and passes south-east through Chaumont, Langres, and Fay-le-Billot. The road from Paris to Bar-le-Duc and Strasbourg just crosses the northern corner of the department through St. Dizier, from whence a road follows the valley of the Marne through Joinville and Vignory to Chaumont. A road from Langres leads to Dijon (Côte d'Or), sending off a branch road by the way to Gray (Haute Saône) and Besançon (Doubs): another road from Langres leads along the valley of the Meuse to Neufchâteau (Vosges); and a road from Troyes (Aube) to Toul and Nancy (Meurthe) crosses the department through Doulevant and Joinville. There are several departmental roads, of which about 136 miles are in repair. There are a great number of bye-roads and paths, with an aggregate length of above 4000 miles.

The soil of the department varies much, but is on the whole fertile: the vegetable soil rests chiefly on a calcareous subsoil. There are fertile plains, beautiful valleys, and well wooded heights; with here and there naked and barren rocks. Agriculture has undergone considerable improvement; the marshes and other tracts previously uncultivated have been for the most part turned to good account. More than half the soil of the department is under the plough. The quantity of wheat and of buckwheat grown, though below the average of the departments of France if quantity alone be considered, is considerably above the average if taken in relation to the population; the quantity of rye and maslin, and of potatoes, is far below the average, however regarded: that of barley and of oats nearly twice the average. Pulse, rape, and mustard are grown; together with a considerable quantity of gentian and other medical herbs. Walnut-trees and cherry-trees are numerous. The cultivation of the vine is an object of considerable attention: the vineyards cover 32,000 or 33,000 acres, and are remarkably productive. The wines of Aubigny and Montsaugeon, on the south-eastern slope of the heights of Langres, are red wines of the first class; those of Vaux, Rivière-les-Fosses, and Prautboy are among the best of the second class. The grass lands constitute about one-tenth of the department; more than half of them are meadows, the rest are heaths or commons, or other open pastures. The number of horses reared is very great. They are of small size and middling quality. The number of horned cattle is about equal to that in the average of the departments; but relatively to the population is above the average. Cows predominate and are considered excellent milkers. The sheep are much esteemed for their flesh; but the quantity of wool grown is not considerable. Goats are numerous; but pigs not so. Bees are very generally kept, and in some places a great number of turkeys are reared. The rivers and pools yield fish and crayfish; small game is abundant; and the forests and mountains are the haunts of the wild boar, the wolf, the fox, the roebuck, and the stag.

The woodlands are extensive, and their produce forms an important article of export. The chief timber is oak and beech. It was estimated twelve years ago that above 30,000 tons of firewood, and 15,000 tons of timber, both of oak, were yearly sent down the Marne to Paris; 10,000 tons of ship timber and 1,200,000 deals, of the weight of 12,000 tons, with 2500 tons of fir poles with the bark on, were also yearly sent down the Marne from St. Dizier, chiefly to Paris. The exportation of timber and faggots from the department has probably increased since that period, with the growth of the population of Paris.

The department is divided into three arrondissements, as follows:—

Name.	Situation.	Area in sq. miles.	Population in 1831.	Population in 1836.	Communes.
Chaumont	Central	967	84,965	87,271	195
Langres	S.E.	838	98,422	100,528	210
Vassy	N.W.	615	66,440	68,170	145
		2420	249,827	255,969	550

There are twenty-eight cantons or districts, each under a justice of the peace.

In the arrondissement of Chaumont are Chaumont, distinguished as Chaumont en Bassigni (pop. in 1831, 6104 town, 6318 whole commune; in 1836, 6318 for the commune) [CHAUMONT], and Vignory, on or near the Marne; La Ferté-sur-Aube on the Aube; Arc-en-Barrois and Château-Vilain on the Aujon; Nogent-le-Roi on the Treyre; Andelot on the Rognon; Bourmont on the Meuse; and Reynel and Saint Blain between the Rognon and the Meuse. There are iron-works at La Ferté. Château Vilain (with a population amounting probably to nearly 2000) also has some iron-works; and the inhabitants manufacture black calf-skin. Nogent-le-Roi (pop. 2314 town, 2401 whole commune) has a considerable manufacture of cutlery. Bourmont (with a population scarcely exceeding 1000) is the centre of a district in which the same manufacture is carried on to a considerable extent. The town is delightfully situated, and commands an extensive view of the valley of the Meuse: it has a public library.

In the arrondissement of Langres are Langres (pop. in 1831, 5960 town, 7460 whole commune; in 1836, 7677 whole commune [LANGRES], near the source of the Marne; Fay-le-Billot (pop. 2331 town, 2411 whole commune), near the source of the Salon; and Bourbonne-les-Bains [BOURBONNE-LES-BAINS] on a feeder of the Saône. Fay-le-Billot has bleaching grounds; the inhabitants carry on trade in basket-work and leather.

In the arrondissement of Vassy are Vassy (pop. in 1831, 2323 town, 2583 whole commune; in 1836, 2694 commune), Doulevant and Eclaron on the Blaise; Sommevoire and Montierender on the Voire; and St. Urbain, Joinville (pop. 3013 town, 3052 whole commune), and St. Dizier (pop. 5951 town, 6197 whole commune), on or near the Marne. Vassy, or Wassy, is known in history for the collision which took place between the retinue of the duke of Guise and a Huguenot congregation, which led to the massacre of many of the latter, and was the immediate cause of the religious wars of the sixteenth century in France. The manufactures of the town are yarn, druggets, woollen cloths, nails, and leather. The neighbourhood abounds with iron-works. Sommevoire, or Sommevaire, has a small woollen manufacture. Joinville has its antient castle, in which were born the Sieur de Joinville, companion and historian of St. Louis in his crusade, and the cardinal of Lorraine, brother of the duke of Guise. Woollen and cotton yarn, and worsted stockings, are made here. At St. Dizier the navigation of the Marne commences. The timber and iron of the department, and the iron of the adjacent department of the Meuse, are deposited in stores here, previous to their being put in boats for Paris, or forwarded by land carriage, one part to Paris, another to Flanders. Boat-building is actively carried on here; a hundred boats, each of 100 tons burden on the average, are yearly built. Nails and tires for wheels are also manufactured. The town is pleasantly situated, well built, and surrounded with public walks. There is a handsome townhall lately built. Two engagements were fought near this town in 1814, between the French and the allies.

The manufactures of the department are considerable, though checked by the insufficiency of the means of transport. That of iron is the chief. There were in 1834, 71 iron-works of different kinds, with 58 furnaces for producing pig-iron and 124 forges for wrought-iron. Charcoal was the universal fuel. A considerable quantity of fine cutlery is made at Langres, Chaumont, Bourmont, and Nogent-le-Roi; nails, files of every description, iron pipes, and other hardwares; wax candles, paper, leather, gloves, glass, porcelain, stockings, knit and woven, and some woollen cloths are also manufactured. The exports are manufactured goods as above, wax, corn, wine, and timber.

The department constitutes the diocese of Langres, the bishop of which is a suffragan of the archbishop of Lyon et Vienne: it is in the jurisdiction of the Cour Royale and the circuit of the Académie Universitaire of Dijon; and in the eighteenth military division, the head-quarters of which are at Dijon. It returns four members to the Chamber of Deputies.

In respect of education this department is one of the most advanced. It is exceeded only by the three departments of Meuse, Doubs, and Jura. Of every hundred young men enrolled in the military census of 1828-29, seventy-two were able to read and write; while on the average of the whole of France the number was only about thirty-nine.

This department originally constituted part of the territories of the Lingones, a Celtic people; and of the Catalauni and the Leuci, Belgic nations. In the Roman division of Gaul, the Lingones were included in the province of Lugdunensis Prima; the Leuci in that of Belgica Prima; and the Catalauni in that of Belgica Secunda. The limits of the present department included the towns of Andomatunum, the capital of the Lingones, afterward called Lingones, now Langres; and of Aquæ Borvonis, now Bourbonne-les-Bains, also in the territory of the Lingones. On the downfal of the Roman empire this district came into the hands of the Burgundians and of the Franks; and part of it was comprehended in the county, afterwards duchy, of Langres in Champagne, united to the crown A.D. 1179. Another part formed a detached portion of Le Barrois.

MARNES IRISÉES. The French geologists intend by this term to designate the upper party-coloured 'marls' or clays of the new red formation. In Germany these are the Keuper marls, and in England the gypseous and saliferous marls of Cheshire, Worcestershire, Nottinghamshire, &c. (See Sedgwick on 'Magnesian Limestone,' in *Geol. Trans.*; Murchison's *Silurian System*, &c.)

MAROCCO, called by the natives Mogh'rib-el-aksa ('the farthest west'), or briefly Mogh'rib, whence the inhabitants are called Moghribins, is an empire in Northern Africa, which extends from south to north between 27° and 36° N. lat., the most northern districts forming the southern coast of the Straits of Gibraltar, and from east to west between 1° 20' and 11° 36' W. long. On the north it borders on the Mediterranean, on the north-west and west on the Atlantic Ocean, on the south on the Sahara, and on the east on Algiers. Its surface is estimated by Graberg at 274,000 square miles, or about 50,000 square miles more than that of France.

Surface and Soil; Coast.—The surface of this extensive country is extremely diversified by mountains, hills, plains, and valleys. The Atlas traverses it in its greatest length, running, at some distance from its southern and eastern boundary, from Cape Nun on the Atlantic Ocean, to Cape dell' Acqua, west of the mouth of the river Muluia, on the Mediterranean. The general direction of the Atlas is from south-west to north-east; south of 32° it is called the Greater Atlas, and north of it the Lesser Atlas. [ATLAS.] The Greater Atlas, towards its southern extremity, consists of two ranges, both beginning near the Atlantic; the southern, commencing at Cape Nun (south of 29°), is called Mount Aidar, and the northern, commencing at Cape Ghir (south of 31°), or Ras Afurni, bears the name of Mount Bebauan. The two ranges unite about 31° N. lat., and about 100 miles from the shore. Between these two ranges is the plain of Tarudant, or Sus-el-aksa. Both the ranges, as well as the remainder of the Greater Atlas, are covered with snow for several months in the year, but probably none of the summits attain the limits of perpetual congelation. The Greater Atlas is not very wide, being generally traversed in two or three days. Two mountain-passes lead over Mount Bebauan, one called Bebauan, not far from Cape Ghir, and another called Bibawan, about 60 miles farther east, which connects the town of Tarudant with Frouga, in the plains of Marocco. A third pass is stated by Caillié to lead from the town of Tatta in Drah, or Darra, to the town of Marocco; but it has never been traversed by Europeans. The interior of the range consists of ridges and valleys, and sometimes also mountain-plains: it is well cultivated in some parts, and in others it serves as pasture-ground; towards the southern declivity it is nearly a bare rock.

Between 31° and 32° N. lat., and near 6° W. long., where the range turns more to the north, and takes the name of the Lesser Atlas, the width of the range increases considerably, and as most of the large rivers rise in this part of the Atlas, it was thought that the highest summits also occurred here: some were said to rise to 13,000 feet and upwards, but Caillié, who seems to have traversed this tract in an oblique direction, on his return from Timbuctoo, does not mention any elevated summits, nor does he speak of having seen snow on the mountains. The Lesser Atlas, though, according to appearances, much less elevated than the Greater Atlas, probably occupies a greater width, sending lateral branches to the east and west, between which there are fertile valleys. Near 34° N. lat. and 4° W. long. the Lesser Atlas divides into two branches, of which the eastern runs north-east and terminates at Cape dell'Acqua; the other, called Er Riff, turns first north-west, then west, and again north-west, until it terminates in the high and mountainous coast which forms the southern shores of the Straits of Gibraltar, between Punta di Africa, near Ceuta, on the east, and Cape Spartel on the west. The country which is included between these two lateral ranges of the Lesser Atlas and the Mediterranean Sea is the most extensive mountain-region in Marocco. Though the mountains do not rise to a great elevation, the whole tract is covered with masses of bare rock, with narrow valleys between them. The whole coast-line along the Mediterranean, which from Twunt, or Tawunt, to Cape Spartel is about 220 miles, is high and rocky. Level tracts of inconsiderable extent occur at the mouths of the small rivers only. Mount Abyla, or the Monkeys' Hill, opposite the rock of Gibraltar, rises to a considerable height.

The elevated and rocky coast continues along the Atlantic nearly as far south as the mouth of the river El Kos, or Lucos. The country adjacent to the coast is rather hilly than mountainous, though a few rocky masses rise to 2500 feet; the soil is mostly gravelly, and sustains only a scanty vegetation, with a few trees. The river (wadi) El Kos traverses an immense plain called M'shara-er-Ramla, which extends eastward to the ranges of the Lesser Atlas, and southward to the banks of the river Seboo. Its surface is partly level, and partly traversed by low ranges of hills. Its slope towards the Atlantic appears to be gradual, as the rivers make numerous bends in the plain and have a gentle course. On its western border the sea has formed a range of sand-hills, by which several small rivers are prevented from reaching the ocean, and form along the shores two lakes, the smaller of which, Muley Buselham, is 5 miles long, and the larger, Murja Ras el Dowla ('the lake with the winding head'), 20 miles long by one and a half broad. The range of sand-hills which separates these lakes from the sea is about 250 feet high. The harbours along this low coast are nearly filled up with sand, and can only be entered by small vessels. The plain of M'shiara-er-Rumla, though the soil is light, is very productive in corn, and contains excellent pasture-grounds. It is also connected on the east with the fertile valley that extends east of the town of Fez, between the offsets of the Lesser Atlas.

The plains continue south of the Seboo river to the banks of the Oom-er-begh, or Morbeya, and still farther south; but they gradually change their character, and their fertility greatly diminishes. The country also rises from the sea-shore, which in many places is rocky and inaccessible, and extends in wide plains ascending like terraces one above the other, the eastern being always some hundred feet higher than that immediately west of it, until at the base of the Lesser Atlas they probably attain an elevation of 4000 feet. The inferior fertility of these plains seems to depend more on the climate than the soil, which chiefly consists of a light loam. Water is found only at the depth of from 100 to 200 feet. The rivers run in channels several feet below the surface of the plains. Only isolated spots are cultivated, and there are no trees except stunted palms.

A range of hills, rising between 500 and 1200 feet above the plains, divides them from the southern plain, which extends along the base of the Greater Atlas. Where the town of Marocco is situated, from which it obtains the name of the Plain of Marocco, it is about 25 miles wide, but it grows still wider as it advances westward. This plain, which is drained by the river Tensift, is about 1500 feet high near the town; but it grows lower towards the sea, and terminates, between Cape Cantin and Mogadore, in a low shore, generally sandy, and sometimes rocky. In fertility it is much superior to the central plains.

The plain of Tarudant, which is the most southern, lies between the ranges of the Bebauan and Adrar mountains. It appears to be traversed nearly in the middle by a range of hills which divide it into two wide valleys. The northern, which alone has been visited by Europeans, is level, and of great fertility, as the extensive woods and plantations of olive-trees show, but the greater part of it is uncultivated.

The countries east of Mount Adrar and south of the Greater Atlas are known under the names of Draha or Daraa, Tafilet, and Segelmesa, and are parts of the Bilud-ul-Gerid, or the 'country of the palms.' They have not been visited by any European except Caillié, who represents them as situated within the range of the Atlas, and as consisting of valleys and small plains, enclosed by low and sterile hills. The valleys and plains are also frequently rocky, and exhibit a scanty vegetation; but some parts are cultivated or covered with extensive groves of date-trees.

That portion of the empire of Marocco which lies on the east of the Lesser Atlas, and comprehends the basin of the river Mulwia, has never been visited by Europeans. According to Graberg, the southern part of it, near the sources of the river, contains some fertile plains or valleys, which are good pasture-grounds; but the northern districts are said to be occupied by two sterile regions, the deserts of Aduhra and Angad.

Rivers.—The Mulwia, or Muluya, which rises at or near the southern extremity of the Lesser Atlas, and runs northward into the Mediterranean Sea, has a course of about 400 miles; but as it traverses a country which has not been visited by Europeans, its peculiarities are not known. It is the only considerable river in Marocco which falls into the Mediterranean. Seven rivers fall into the Atlantic Ocean. The most northern, the El Kos, or Luccos, rises in the range of Er-Riff, and in its course of nearly 100 miles is used to fertilise the adjacent country by irrigation. Farther south is the Seboo river, which rises in numerous branches on the western declivity of the Lesser Atlas, and is joined by several affluents which descend from the southern declivity of the range of Er-Riff. After a course of about 230 miles it enters the Atlantic, near the town of Mehedia. Though a considerable river, with rather a large volume of water when compared with other rivers of this country, its mouth does not afford a harbour; a bar of sand, a quarter of a mile from its outlet, extends almost across, and is nearly dry at low-water of spring-tides. Inside the bar there are from three to four fathoms water, and the tide rises seven or eight feet. The waters are used for irrigating the adjacent country.

Bu Regreb is an inconsiderable river running hardly more than 100 miles; but its waters are used for irrigation, and its mouth forms the harbour of the towns of Salé or Sla, and Rabatt or Arbat. A bar, about one-eighth of a mile from the entrance, runs almost across in a west-south-western direction, with three or four feet water on it at low-water, leaving a channel at each end. The north-eastern channel is that which is used. The tide rises from nine to ten feet; inside, the harbour is sheltered, and has sufficient water for a frigate.

The Oom-er-begh, or Morbeya, the largest of the rivers that fall into the Atlantic, likewise rises in several branches in the western declivity of the Lesser Atlas, and probably runs more than 300 miles. In the upper part of its course it fertilises several valleys; but in its course through the plains it flows between high banks of sandy clay, and cannot be used for the purpose of irrigation. At its mouth is the small town of Azamor, which has no commerce: a bar of sand which lies across the mouth of the river is almost dry at low-water, and boats alone can enter it.

The Tensift, which waters the plain of Marocco, rises in a subordinate range of high hills, about 40 miles east of the town, and runs nearly 150 miles with a winding course. It is very probable that the mouth of this river also is closed by a bar.

Through the plain of Tarudant, or Sus-el-acsà, flows the river Sus, which rises in Mount Bebauan, north-east of Tarudant, and flows westward to the sea, which it enters at some distance south of the harbour of S. Cruz, or Agadir. It may be considered as the southern boundary of the empire, the Arabian chiefs who govern the country south of it being only nominally subject to the emperor of Marocco.

The most southern river which falls into the Atlantic is the Draha, or Daraà. Until lately it was supposed that this river was lost in the moving sands of the Sahara; but according to the statement of Wilkinson (*London Geographical Journal*, vii.), it reaches the sea 32 miles south-west of Cape Nun, where it is called on our maps Akassa. If this statement is true, the Draha, which rises on the southern declivity of the Greater Atlas, south-east of the town of Marocco, must have a course of more than 500 miles; but nearly the whole of it is unknown. It is however said that it flows through the productive districts of Draha and El Harib; and that two considerable towns, Tatta and Akka, stand on its banks.

From the southern declivity of Mount Atlas descend three other rivers, the Fileli, Ziz, and Ghir. We are not further acquainted with them than that they run southward, and are lost in the sands of the Sahara.

Climate.—The climate is not so hot as might be expected from the position of this country. A great part of the empire is subject to the alternation of the sea and land breezes, and those districts which lie beyond their reach are cooled to some extent by the winds which blow from the mountains. Frost and snow only occur on the mountains. Along the sea the thermometer never falls below [illegible] or 40°; and even in the hottest places, at S. Cruz and Tarudant, it generally does not rise above 84°, and rarely to 90°. The seasons are divided into the dry and wet. The wet season happens in our winter. Abundant rains fall towards the end of October, and last [illegible] about three weeks: these rains are followed by some dry weather, but they set in again about the middle of November, and showers are frequent till the month of March, when the dry season begins, which is rarely interrupted by showers. The rains are less general and frequent south of the river Seboo, and also less certain, which is probably the cause of the inferior fertility of these districts, as they are subject to frequent drought. Little is known of the climate south of Mount Bebauan, except that the heat is very great, and that the southern declivity of Mount Atlas has no rain, being exposed to the dry and hot winds that blow from the Sahara and disperse the few vapours which occasionally rise

Productions.—Besides wheat and barley, which are extensively raised in most of the districts of the plains, rice, Indian corn, and holcus sorghum, or dhurra, are cultivated, especially the last-mentioned species of grain, which is very prolific, and constitutes the principal food of the lower classes. Other objects of cultivation are cotton, tobacco, sesamum, hemp, saffron, and different kinds of beans and peas. The plantations of olive-trees and almond-trees are very extensive. The fruit-trees of southern Europe are also common, especially the fig and the pomegranate. The date-tree is only cultivated on the southern declivity of Mount Atlas, and the best comes from Draha and Tafilet.

In the districts south of the Omm-er-begh there are large plantations of henna (Lawsonia inermis).

The southern declivities of Mount Atlas are bare, but on the northern there are extensive forests, consisting of the olive, carob (Ceratonia siliqua), walnut, acacia, cedar, stunted palms, and rose-trees, and also cork-trees. The timber is fine, but not large.

Domestic animals of every kind are numerous. The horses are distinguished by their beauty, those of the native breed as well as those of Arab origin; the sheep, which are considered as indigenous, and are supposed to have spread from the declivities of the Atlas over all the world, produce a wool not inferior to any for softness, fineness, and whiteness; sheep and goats are more numerous than any other domestic animals. Goat-skins constitute one of the most important articles of export. Cows, asses, mules, and camels are also reared in considerable numbers. In the large uncultivated tracts wild animals abound, as lions, panthers, hyænas, wolves, and several species of antelopes and deer; as well as monkeys and wild boars. Wild boars are abundant in all parts, but most of the other ferocious animals are limited to the southern regions. Ostriches are found in the desert bordering on the southern and eastern districts, and their feathers constitute an article of export. Cranes and storks abound. The locusts sometimes lay waste the provinces bordering on the deserts. Bees are common, and wax is exported.

The mineral wealth of Marocco is very imperfectly known. Metals seem to occur in the greatest abundance on the southern declivity of Mount Atlas, especially in those parts which surround the plain of Sous-el-aksa, where gold and silver occur, but not in abundance; the latter occurs in the river Draha or Akassa (Assaka). Copper, which in Strabo's (p. 830, Casaub.) time was worked in these countries, is still abundant; the richest mine which is worked is near Tesselight, in Sous-el-aksa, but there are others in the neighbourhood of Tarudant. Lead is found in Mount Atlas and in the Lesser Atlas. Iron is worked in several places; and there is also antimony. Rock-salt is also said to be abundant, but is not worked. The several small lakes which lie along the sea-shore are natural salt-pans, which produce this useful article in abundance. Fullers'-earth, which is considered not inferior to the English, occurs in several places.

Inhabitants.—The population of this empire is differently estimated. Jackson thought that it amounted to fourteen millions, which number is reduced by Captain Washington to five or six millions. Graberg assigns to it 8,500,000 inhabitants, and states that the population is composed of the following nations, in this proportion:—

Amazirghis, namely,	
Berbers . . .	2,300,000
Shelluhs . . .	1,450,000
Arabs, namely,	
Moors, Lodayas, and other mixed tribes	3,550,000
Beduins, and others of pure blood .	740,000
Jews . . .	339,500
Negroes, slaves and freemen from Soudan,	
Foulahs, Mandingoes, &c. .	120,000
Europeans, Christians . .	300
Renegadoes . . .	200
	8,500,000

The Amazirghis, or Mazirghis [Berbers], are the most ancient inhabitants of Northern Africa, and one of the most widely-spread nations of that continent, as is proved by the language, the different dialects of which are spoken by the tribes which extend from the banks of the Nile to the Atlantic, as the Tibboos and Tuaricks of the desert, the Kibbils in Segelmessa and Tafilet, and the different Shelluh tribes on the Atlas and Mount Bebauan. Most of the tribes occupying the southern districts of Tunis and Algiers also speak the same language. The Amazirghis in Marocco are divided into Berbers and Shelluhs. The Berbers occupy exclusively the mountain-region which extends along the Mediterranean, where they are called Riffins, from inhabiting the mountains of Er-Riff, and are divided into several tribes. Other tribes are spread over the mountains of the Lesser Atlas and the basin of the river Mulwia as far south as the course of that river. The Shelluhs occupy the Greater Atlas and its great branches Mount Bebauan and Mount Adrar. It is now the general opinion that their languages are only dialects of one language; but the tribes differ somewhat in their physical character and in their customs. The Berbers are nearly white, of middle size, well formed, and rather robust and athletic; their hair is frequently fair, resembling that of the northern people of Europe rather than any nation of Africa, and they have very little hair on their chins. They live generally under tents, or in caves situated on steep and nearly inaccessible mountains. They pay little regard to the orders of the sultan, and obey only their hereditary princes or chosen magistrates. In the plains they build houses of stone or wood, but always enclose them with walls. Their chief occupation is that of huntsmen and herdsmen, yet they cultivate some patches of ground and rear bees.

The Shelluhs are chiefly agriculturists, and exercise several trades; their houses are always built of stone, and covered with tiles or slates. They are less robust than the Berbers; their colour is sallow, and they resemble in some measure the Portuguese, from whom some authors think they are descended. They are much more advanced in civilization than the Berbers.

The Moors are the most numerous of the nations that inhabit Marocco. Their language, which is called Mogrebi, or Occidental, is a dialect of the Arabic; but it is intermixed with many words from the language of the Amazirghis, and still more with Spanish words. The latter circumstance may be ascribed to the emigration of their ancestors from Spain after the conquest of Granada. These emigrants settled in the towns and plains along the Atlantic.

The Moors of Marocco are of middling size, and rather slender when young, but grow stout as they advance in years. Their colour varies between yellow and black, which is principally to be ascribed to their frequently marrying black women from Sudan. They are the only nation of Marocco with which the Europeans have an immediate intercourse, and they are the principal inhabitants of the towns; they fill the high offices of government, and form the military class. [Moors.]

The Arabs are the descendants of those who emigrated at the time when the Mohammedan religion was diffused from the Hejas, Yemen, and Hadramaut. A few families live in the towns, but the Beduins are dispersed over the plains, where they adhere to their wandering life, living in tents, and following the pastoral occupation. They are a hardy race, slightly made, and under the middle size. Their language is the Koreish, or Arabic of the Koran, which they pretend to speak in its purity.

The Jews are intermixed among all these nations: their condition is best among the Berbers, where they follow different trades; but among the Shelluhs and Moors they are much oppressed, and exposed to the most ignominious treatment. They are very numerous in the seaports and commercial towns.

The negroes, who are imported as slaves, frequently obtain their liberty; and as they are distinguished by fidelity, the emperor has thought it expedient to form his body-guard of them, which is the only standing army of the empire, and at present not above 5000 strong.

Manufactures.—As the inhabitants dress chiefly in wool, the manufacture of woollen cloth is general, but the material is usually coarse. In some places however there are manufactories on a large scale, which supply articles of export. In the town of Fez the red caps are made which are used in all the countries that border on the Mediterranean, besides several kinds of silk goods, especially scarfs, which are used like girdles, and sometimes are interwoven with gold thread. The best kinds of silk stuffs, called *Cahuam*, are made of silk imported from Syria; the more common material is got from the Beduins, whose wives rear silkworms. The inhabitants of Fez are also distinguished as goldsmiths, jewellers, and cutters of precious stones; many of them are also occupied in making marocco leather and different kinds of earthenware.

Tanning is well understood. Very good leather is made in the neighbourhood of the towns of El Kasar and Mekinez. The tanyards in the capital are very extensive, and the leather which they produce is superior to any made in Europe. The tanners possess the art of tanning the skins of lions and panthers, and giving them a snow-white colour, with the softness of silk. The marocco leather of the capital is yellow, that made in Tafilet green, and in Fez it is dyed red. Their bright colours are considered inimitable in Europe. Very good sole-leather is made in Rabatt and Tetuan.

Carpets are chiefly made in the province of Ducalla, south of the river Oom-er-begh, and are known in Europe by the name of Turkey carpets. They are much esteemed for their colours and the great variety of the pattern: the better kinds are very dear.

Political Division and Towns.—The empire of Marocco is composed of the two kingdoms of Fez and Marocco, of which the former occupies the countries north of the river Oom-er-begh and the basin of the river Mulwia: the kingdom of Marocco comprehends the remainder, with the exception of the countries south of the Greater Atlas and Mount Bebauan, which are considered as a separate kingdom, called that of Tafilet. At present the whole country is divided into thirty governments, of which fifteen belong to Fez and fifteen to Marocco. In the latter the country between Mount Bebauan and Mount Adrar is included. The countries of Draha, Tafilet, and Segelmesa are divided into two other governments.

Along the coast of the Mediterranean the Spaniards possess Melilla, near Ras-ul-dir, or Cape Tres Forcas, and farther westward Alhucemas and Peñon de Velez, three small fortresses, which have no communication with the interior.

Not far from the Straits of Gibraltar is Tetuan, built on the declivity of a hill, about half a mile from a small river (Martil) which falls into the Mediterranean about five miles from the town: the mouth of the river forms a harbour for vessels of middling size. It carries on a considerable commerce with Spain, France, and Italy, exporting wool, barley, wax, leather, hides, cattle, mules, and fruits, of which the valley of Tetuan produces abundance of the finest quality. The streets are narrow and unpaved. The population is 18,000 (Graberg), or 40,000 (Semple).

Near the eastern entrance of the Straits of Gibraltar is the Spanish town of Ceuta [CEUTA], and near the western the town of Tangier, where the European consuls-general reside. Tangier is built on a hill, near a spácious bay, 14 miles west of Cape Spartel, and its harbour is defended by three small fortresses. The streets are wider and straighter than in other towns of the empire; but except the houses of the European consuls, and a few belonging to rich persons, they are all small and inconvenient. The Jews have here several synagogues, and the Roman Catholics have a church, the only Christian establishment of this kind in the empire. The commerce of this place is limited to some trade with Gibraltar and the opposite coast of Spain. The population is 9500 (Graberg), or 8000 (Washington).

Along the Atlantic, from north to south, are the following towns: El Araish, or Larash, at the mouth of the river El Kos, containing 4000 inhabitants (Graberg and Washington), has a good harbour; the bar at the mouth of the river has 16 feet of water at spring-tides, and spacious anchoring-ground within, with water enough for frigates. Sla, or Salé, and Rabatt, are separated from each other by the river Bu Regreb, which forms their common harbour; they contain together 50,000 (Graberg) or 31,000 inhabitants (Washington). Salé, formerly noted for the boldness of its pirates, is badly built and partly in ruins; but Rabatt is a thriving town, and has some good streets. Its commerce is still considerable, though a portion of it has been transferred to Mogadore, and its trade with Genoa and Marseille is extensive. The principal articles of exportation are wool, corn, and wax, and the manufactured goods of Fez and Mekinez. The European and East India goods, destined for Fez and the northern provinces, are imported through this town. Saffi, or Asafi, farther south, not far from Cape Cantin, is between two hills in a valley, and is subject to inundations. It formerly exported many products of the country, as its roadstead affords excellent anchorage; but since the rise of Mogadore it has been on the decline. The population is 12,000, including 3000 Jews.

Mogadore, or Suera, as the Moghrebins call it, the port of the town of Marocco, lies on the sea-shore between Cape Cantin and Cape Gher. It was founded in 1760. Mogadore is built on a low shore, consisting of moving sand, which extends from 5 to 15 miles inland, where a fertile country begins. It is regularly built, the streets being straight, but somewhat narrow. The Europeans settled here have erected several large buildings in the African style. The town is divided into two parts, one of which is called the Fortress, and contains the custom-house, the palace of the Pasha, the other public buildings, and the houses of Europeans; the other part is only inhabited by Jews. The harbour is formed by a small island, lying south west of the town and about two miles in circumference. At low tides there are only 10 or 12 feet of water in the harbour, and large vessels are obliged to anchor without, at a distance of about two miles. The commerce of this place with London, Amsterdam, Cadiz, Leghorn, Genoa, the Canary Islands, Hamburg, and the United States of America, is considerable. The population is 10,000 (Jackson), or 17,000 (Graberg).

Agadir, or S. Cruz, farther south, has a good harbour, and formerly carried on a considerable trade, which however was transferred to Mogadore by order of the government.

In the interior there are several populous towns, of which the following are the principal: Teza, or Taza, on one of the upper branches of the Seboo river, in a very fertile country, has 10,000 or 12,000 inhabitants (Graberg), some manufactures, and a considerable trade with Tlemsan in Algiers (being situated near one of the most frequented passes of the Lesser Atlas), and with Fez. Al Kassar, or Ksar, on the El Kos river, is well built, and has some manufactures, with 8000 (Washington) or 5000 (Graberg) inhabitants.

Fez, or Fas, the most industrious and commercial town of the empire, is situated in a valley which is drained by one of the upper branches of the Seboo river. It contains upwards of 100 mosques and seven public schools with numerous pupils. The mosque called El Karubin is a magnificent building, and that of Mula Driss, the founder of the town (807), is the object of many pilgrimages and an asylum for thieves and murderers. The imperial palace, with the buildings and gardens annexed to it, occupies a great space. The number of persons employed in manufactures is considerable. Every trade is carried on in a separate street; generally only one kind of goods is sold in each shop. The commerce of this town with the seaports, especially Rabatt, and by means of the caravans with Tunis, Kahira, and Sudan, is very great. The streets are narrow, and, owing to the great height of the houses, also dark: there are numerous extensive caravansaries, or public inns, where the travelling merchants find lodging. The population is 88,000 (Graberg), or 20,000 (Caillié).

Mekinez, or Miknas, west of Fez, a large town built on a hill in a wide and fertile plain, has also narrow crooked streets. It has many manufactures, especially of leather. The imperial palace is more than two miles in circuit, and has large orchards and gardens annexed to it. The population is 56,000 (Graberg).

Tefza is situated in one of those fine valleys which are watered by the numerous branches of the Oom-er-begh, not far from the base of the Atlas. It has large manufactures of woollen cloths, which are exported to Italy and elsewhere. The population is 10,500 (Graberg).

Demnet, or Dimnit, a considerable place east of the town of Marocco, near the base of a branch of Mount Atlas, carries on a considerable trade. The caravans which go from Marocco to Draha and Sudan here begin to ascend the mountain-pass which leads to Tatta.

Marocco, the capital of the empire and the residence of the sultan, is situated on level ground, four miles south of the river Tensift, and is surrounded by a strong wall [illegible] feet high, with square turrets at every fifty paces. The walls are near six miles in circuit, but the area enclosed is far from being covered with buildings, there being several large gardens and open spaces. The streets are narrow and irregular, and in many cases, as in Fez and Mekinez, connected by arches and gates. Several open places, which cannot be called squares, are used as market-places. The houses, which are only of one story, have flat roofs and terraces, like those of Spain, and the rooms open into a court, which is sometimes surrounded by arcades and embellished by a fountain. The houses have no windows, no fire-places, and no furniture, except a cushion or two. Large aqueducts, which convey the water of the river Tensift to the city, surround it, and some of them are ten or twelve feet deep. They are continued southward towards the Atlas, in some places to a distance of 20 miles. These aqueducts supply the fountains with water; the fountains are numerous, and some of them have traces of delicate sculpture. On the south of the town, but without the walls, is the imperial palace: a wall of a quadrangular form, enclosing a space about 1500 yards long by 600 wide, is equal in strength and height to the walls of the town. The enclosed space is divided into squares, laid out in gardens, round which are detached pavilions, forming the imperial residences. The floors of the rooms are tessellated with various coloured tiles, but otherwise they are plain, the furniture consisting of a mat, a small carpet at one end, and some cushions. There are nineteen mosques, two colleges or medresses, and one hospital in this town. The principal mosque, El Koutubia, is distinguished by a lofty tower, 220 feet high, a master-piece of Arabic architecture. The *bazaar*, or *kaisseria*, is a long range of shops, covered in and divided into compartments, in which the productions of the agricultural and manufacturing industry of the country, as well as goods from China, India, and England, are exposed for sale. There are some manufactures: the tanneries of Marocco have been already mentioned. Capt. Washington states that the population cannot exceed 100,000, and is perhaps not above 80,000, including 5000 Jews; Graberg assigns it only 30,000 inhabitants. Plague and famine have reduced a population which was formerly much greater.

In the province of Sus-el-acsa is Terodant, once the capital of a separate kingdom, about 60 miles from the seaport of Agadir or S. Cruz. It is built in the middle of an extensive plain, and its walls, which are now in a ruinous state, are very extensive. The houses are low and built of earth, and each of them is surrounded by a garden and wall, so that the place rather resembles a well peopled country, than a town. The inhabitants are industrious, and the woollen dresses and marocco leather made here are much esteemed; copper and saltpetre are abundant in the neighbourhood, and a considerable quantity of the copper is made into domestic utensils in this town. The population is 22,000 (Graberg).

In this province are also the towns of Tedsi, with 15,000 industrious inhabitants (Graberg), and Tagavost, which is said to be more populous. Farther to the south-west, near the banks of the river Draha, is the village of Nun, 30 miles from the sea, with 2000 inhabitants. It is one of the points from which the caravans depart for Sudan.

On the southern declivity of Mount Atlas are Tafilet and Tatta, two other places from which the caravans start on their route to Sudan. The former is said to be a considerable place, with 10,000 inhabitants (Graberg), but Caillié in traversing this country neither saw nor heard of any town of this name.

Education.—The Moors send their children to school at the age of six years. The elementary schools, which are very numerous, both in the towns and in the country, are either private or public establishments. The former are called *mesid*, or *mektib*, and the latter *jamâ*. In these schools reading, writing, and correct pronunciation are taught; the children also learn by heart some passages of the Koran. The method of teaching resembles in some respect that of Bell and Lancaster, which seems to have been used in the East from a very early time. In a few schools, established for girls, they teach reading and writing, and some things which are connected with domestic economy. Boys sometimes remain in these schools until they know the whole of the Koran by heart, when they pass for their further education into the higher schools, called in the singular *medersa*, and in the plural *medaris*, where they are prepared for the university of Fez, called Dar-el-I'lm (or the House of Science), or other colleges. In the colleges they are instructed in grammar, theology, logic, rhetoric, poetry, arithmetic, geometry, astrology, and medicine. The commentaries and traditions relating to the Koran, the laws, legal procedure, and all the formalities to be observed in the courts, are also explained. There are three degrees; students called *taleb*, doctors called *f'kih*, and wise men *a'lem*, in the plural *o'lama*. As there are no printing establishments, calligraphy, called *gedwel*, is enumerated among the sciences.

Commerce.—The Moghrebins carry on a very active commerce with Sudan or the interior of Africa, and with Egypt and Arabia by caravans, and with several parts of Europe by sea. The caravans, when they set out from the commercial towns of Tetuan, Fez, Marocco, and Tafilet, generally consist of about 150 persons and 1000 or 1500 camels, and are then called *cafilas*; but when they have united at Tatta or Akka, on the Draha river, the point where they enter the desert, they consist of about 500 or 600 persons, with 16,000 and even 20,000 camels. Towards the southern border of the desert they come to the oases of Taudeni and El A'rauan, where there are immense deposits of rock-salt, of which they buy large quantities for the market of Sudan. From Timbuctoo, as a central point, the merchants traverse the adjacent countries, exchanging their goods for those of Sudan. They import into these countries rock-salt, woollen cloth and dresses, scarfs, tobacco, Turkish daggers, and blue cloth, and take in return ivory, rhinoceros' horns, incense, gold in bars and powder, ostrich feathers, gum-arabic, cotton, assafœtida, indigo, and slaves. Graberg estimates the annual value of the exported goods at one million of Spanish dollars, and that of the returns at ten times that sum; two-thirds of the imports are again exported to Algiers and Tunis.

The caravans which go to Mecca are chiefly composed of pilgrims, and are much more numerous. They depart only once in the year, and follow two routes. The northern leads from Fez through Teza over the Lesser Atlas, traversing the northern districts of Algiers and Tripoli, in which latter country it may be said to terminate at Kairwan. Hence it passes southward through Gadamis and Fezzan to Alexandria and Kahira, and ultimately to Mecca. The southern road passes from Marocco to Tefza, and thence through the southern districts of Algiers and Tunis to Gadamis and Fezzan, whence it leads to Alexandria and Mecca. Indigo, cochineal, ostrich-feathers, skins, and leather, with the woollen articles manufactured in Fez, Tefza, and Tafilet, are exported by these caravans, and they import the cotton and silk goods of India, some Persian silk-stuffs, rose-oil, amber, musk, balsam, and spices, but particularly cotton, wool, and raw silk. The raw silk is chiefly purchased at Kahira, and Graberg thinks that the annual transactions of the caravans in that town amount to two millions of Spanish dollars.

European vessels visit the harbours of Tetuan, Rabatt, Salli, and Mogadore, and export the produce of the empire to Italy, France, Spain, England, and Holland. The principal goods exported are:—wool of good quality, which goes principally to Genoa, Marseille, and Holland; wax, to Leghorn, Marseille, Cadiz, Lisbon, and London; hides of cattle and camels, to Leghorn, Marseille, and London; gum-arabic, which is inferior to that brought from the Senegal, mostly to London and Holland; copper, to Holland; bitter and some sweet almonds, from Mogadore to Holland; goat-skins, especially those brought from Tafilet, to England; oil, made of the fruits of the elaeodendron argan, or argan-oil (Graberg), and also olive-oil; archil; ivory, especially to Holland; ostrich-feathers, white and grey, to England; dates, to England and Lisbon; and corn, to all places where its exportation is permitted. Among the less important articles are some manufactured in the empire, as scarfs of wool and silk, red or yellow marocco leather slippers and shoes, the black cloaks of Tarudant, and the shawls of Fez and Tefza.

Among the goods which are imported, the cotton-cloths brought from the East Indies and from England constitute by far the most important articles. There are also imported different kinds of woollen stuffs; raw silk and silk stuffs; colonial merchandise, especially sugar, pepper, and ginger; very little coffee is used, but much tea; opium, arsenic, mastich, cochineal, alum, bar-iron from England; steel from England and Trieste; iron-wire, tin and nails, corals, looking-glasses, knives, cotton, brimstone, earthenware, and glass. In 1831 the number of vessels which entered the seaports was sixty-four, and the tonnage 3579 tons. In the same year ninety-four vessels left the ports, with a tonnage of 5842 tons. The imports were valued at 172,000*l.*, and the exports at somewhat more than 151,000*l.*

Government.—The government is absolutely despotic, even more so than in the Turkish empire; the people are much oppressed, and the Christian merchants exposed to great losses by capricious ordinances.

(Gråberg of Hemsö, *Specchio Geografico e Statistico dell' Impero di Marocco*; Jackson's *History of Marocco and Shabeeny*; Washington, in the *London Geographical Journal*; Lempriere's *Tour from Gibraltar to Tangier*, &c.; Caillié's *Travels through Central Africa*, &c.; and Semple's *Second Tour in Spain*, &c.)

MARONITES, the name of a community of Christians belonging to the Western or Roman church, and living on Mount Lebanon. They are neighbours of, and allied to, and in some places mixed with the Druses, and, like them, independent, in great measure, of the Turkish power. The Maronites occupy the valleys and fastnesses of the principal ridge of Lebanon east of Beyroot and Tripoli, and they extend inland as far as the Bekaa, or plain between the Libanus and Anti-Libanus, where they are mixed with the Druses, though they do not intermarry with them. The town of Zhaklé, in the valley of Bekaa, contains between ten and twelve thousand inhabitants, chiefly Maronites. There are also many Maronites at Beyroot and Tripoli; but the tract of country in which the great bulk of the Maronites reside is called Kesrouan. It extends along the ridge of Libanus from the Nahr el Kelb, a stream which enters the sea 12 miles north of Beyroot, to the Nahr el Kebir, which enters the sea north of Tripoli, near the island of Ruad, the antient Aradus, on which side the Maronites border on the Nosaïris, or Ansarieh, who extend to the northward towards Latakieh, and the Ismaelians, who live farther inland near the banks of the Orontes. [Ismaelites.] To the eastward the Maronites have for neighbours the Metualis, a tribe of independent Moslems, of the sect of Ali, who live under their own emir, and occupy the belad or district of Baalbek and part of the Anti-Libanus; and on the south they border on the territory of the Druses, with whom they form one political body, being subject to the Emir Beschir [Druses], in so far as they join him when he calls them to arms for the common defence, and pay him their share of the tribute, which the emir paid formerly to the Porte, and now pays to the pasha of Egypt. But in their internal concerns the Maronites are governed by their own sheiks, of whom there is one in every village, from whose decision there is an appeal to the bishops, who have great authority; and in some cases to the emir of the Druses, and his divan, or council. The clergy are very numerous; the secular parish clergy are married, as in the Greek church; but the regular clergy, who are said to amount to 20,000, and are distributed among about 200 convents, follow the rule of St. Anthony, and are bound by vows of chastity and obedience. The Maronite monks are not idle; they cultivate the land belonging to their convents, and live by its produce. Every convent is a farm The convents are under the jurisdiction of bishops, of whom there is one in every large village. The bishops are under the obligation of celibacy. The bishops collectively elect the patriarch, who is confirmed by the pope, and who resides at the convent of Kanobin, in a valley of the Libanus, south-east of Tripoli, where there is a printing-press, which furnishes the elementary books for the use of the Maronite schools. Not far from Kanobin is the large village of Eden, ten miles above which, and high up the Libanus, is the famed clump of old cedars, called the 'Cedars of Solomon,' of large dimensions, but now reduced to seven in number (Lamartine, *Voyage en Orient*; Richardson), not including the younger and smaller ones. Dr. Richardson measured the trunk of one of the old trees, and found it 32 feet in circumference. The whole clump of old and young trees may be walked round in about half an hour. Old cedars are not found in any other part of Libanus.

At the opposite or southern extremity of the Kesrouan is the handsome convent of Antoura, which is the residence of the papal legate and of some European missionaries. Near it is a convent of Maronite nuns.

The Maronites derive their name from a monk of the name of Maro, who, in the fifth century, collected a number of followers, and founded several convents in these mountains. When the Monothelite heresy prevailed in the East in the seventh century, and was favoured by the court of Constantinople, many Christians who did not embrace its tenets took refuge in the fastnesses of Libanus, around the convents, and thus the name of Maronites was assumed by the population of the mountains. This is the account of the Maronites themselves: others pretend that the Maronites were Monothelites, who took refuge in the Libanus after the emperor Anastasius II. had condemned and proscribed their sect, in the beginning of the eighth century. [Eutychians.] Joseph Simonius Assemani, and his friend Ambarach, better known as Father Benedetti, have defended the Maronites from the charge of Monothelitism. Ambarach translated from the Arabic into Latin the work of Stephen, patriarch of Antioch, concerning the origin and the liturgy of the Maronites. In 1736, at a great synod held at Marhanna, the Maronite church formally acknowledged the canons of the Council of Trent, but they retained the mass in the Syriac language and the marriage of priests. Before that time they received the sacrament under both forms, as in the Greek church. At mass the priest turns towards the congregation and reads the gospel of the day in Arabic, which is the vulgar tongue.

The Maronite population is said to be above 200,000 individuals, and to contain between thirty and forty thousand men fit for military service. Every Maronite is armed, and they are all soldiers in case of need. Volney reckoned them, in 1784, at 120,000, but the population has been rapidly increasing since that time. Their language is Arabic, and by their appearance and habits they belong to the Arabian race. They are a fine-looking people, high-spirited, civil and hospitable, especially towards European travellers, and perfectly honest. Robbery and other acts of violence are hardly known among them. They are altogether an interesting race, full of vigour, and perhaps destined with the Druses to act an important part in the future vicissitudes of Syria. (Jowett, Light, Lamartine, and other travellers in Syria.)

There is at Rome, on the Quirinal Mount, a convent of Maronite monks, who perform the service of the mass in the Syriac language, according to the liturgy of their country. This church was founded by Pope Gregory XIII., and is dedicated to St. John. The monastery serves as a college for young Maronites who come to Rome to study and take orders, after which they return to their own country. It is one of those exotic colonies which give a peculiar interest to the city of Rome.

The ceremonies of these Maronites of Rome on great festivals, their chanting in Syriac, and their curious musical instruments, are described by the Abbé Richard, in his 'Voyage en Italie.'

MAROONS. [Jamaica.]

MAROT, CLEMENT, born at Cahors in 1495, entered the service of the duchess of Alençon as page. He afterwards followed Francis I. to Italy, and was wounded and taken prisoner at the battle of Pavia. On his return to France he wrote poetry for Diana of Poitiers, the king's mistress, who showed him favour; but having presumed too much upon his familiarity with her, she discarded him, and he was soon after put in prison, through her agency as some have believed, in 1525. During his imprisonment he wrote his 'Enfer,' a satire against the lawyers, and he revised his 'Roman de la Rose.' When Francis I. returned from his Spanish captivity, Marot was released, and re-appeared at court. Margaret, queen of Navarre, was much pleased with him; but as usual his vanity made him too presumptuous, and he fell into disgrace. He then turned Calvinist, and went to Geneva; but soon finding himself in an atmosphere little suited to him, he returned to Lyon, abjured Calvinism, and served again under Francis I. in the Italian campaign of 1535. Some years afterwards he published a French version of part of the Psalms, which was read with pleasure, but the Sorbonne condemned it, and Marot took refuge at Turin, where he died in poverty in 1544. He wrote epistles in verse, elegies, satires, ballads, rondeaux, and epigrams. His style has the simplicity of his age, united with grace and poetical fancy. He left a natural son, Michel Marot, who was also a poet. The works of both father and son were published together at Lyon in 4 vols. 4to., 1731.

MARPURG. [Marburg.]

MARPURG, FRIEDRICH WILHELM, a very eminent writer on the theory of music, was born in 1718, at Sechausen in Prussia. According to M. Fayolle he was a counsellor of war to Frederick II. of Prussia, but his friend Gerber says that he was secretary to one of that king's ministers; both however agree that he latterly held the office of director of the lotteries at Berlin. Little more is known of his personal history than that early in life he passed a considerable time in Paris—which probably led to his adop tion of the theory of Rameau, though he was by no means a slave to it—then his learning was considerable, his industry indefatigable, his morals exemplary, and his manners engaging. In 1783 M. Gerber spent some weeks with him at Berlin; he then possessed all the vivacity of youth, and his conversation was witty and agreeable. Shortly after this he began to show symptoms of mental as well as bodily decay, and died early in 1795.

Marpurg is one of the most estimable didactic writers on the subject of music that Germany has produced. 'To a profound knowledge of its principles (says his French biographer) he joined a correct judgment and a refined taste.' 'He was, perhaps,' Dr. Burney remarks, 'the first German theorist who could patiently be read by persons of taste, so addicted were former writers to prolixity and pedantry.' Among his works are two which claim particular notice, his 'Manual of Harmony and Composition' (*Handbuch bey dem Generalbasse, &c.*), and his 'Traité de la Fugue et du Contrepoint.' The first is exceedingly methodical and clear, and may be considered as a musical Euclid. The second would be the best and most complete treatise on fugue and canon that has ever appeared, were it not lamentably deficient in method and arrangement, and also too much devoted to instrumental music, to the exclusion of that of the vocal kind. But in a new edition of this, M. Choron has remedied much of the evil of which there was such ample reason to complain.

Marpurg was author also of many other works, all of them possessing more or less merit, a full and descriptive list of which is given in Gerber's 'Lexicon,' and in the French Dictionary which has supplied part of the foregoing notice.

MARQUE, LETTRES DE. [PRIVATEERING.]

MARQUESAS ISLANDS were so called in honour of the Marquis Mendoza de Canete, by Mendaña de Neyra, who discovered them in 1595; others call them the Mendaña Archipelago. They are situated in the Pacific, and extend about 200 miles in a north-west and south-east direction, between 10° 30' and 7° 50' S. lat. and 138° and 141° W. long. A wide channel divides them into two groups, of which the south-eastern contains five and the north-western eight islands. The latter, having been discovered by the Americans in 1791, are also called Washington's Islands.

The largest islands of the southern group are Santa Dominica, or Hiwaoa, Santa Christina, or Tahuata, and Hood's Island, or Fetoo. They are about 10 miles long from south-south-west to north-north-east. The principal islands of the northern group are, Nookahivah, or Nuhivah, Uahuga, and Uapoa, or Roapoa. Nookahivah, the largest, is nearly 20 miles long from south-east to north-west, and 70 miles in circumference.

An elevated ridge of rocky mountains traverses each island lengthways, and in the larger ones rises to an elevation of 2000 or 3000 feet. The mountains have on both sides high offsets, which extend to the shores of the sea, and thus divide the low land along the shores into valleys, which have no communication with one another except across the highlands that separate them. The mountains in the interior are mostly bare, rugged, and inaccessible. The coast is rocky, abrupt, and beaten by a surf; no coral reef encircles or protects the islands, though the detritus of coral is abundant on the beach. Nookahivah is of volcanic origin, which may be the case with the rest also. The soil is rich; in the valleys it is clay, mixed with vegetable mould, but on the lower declivities of the hills it is thin, and covered by coarse grass in tufts. There are numerous harbours, and many of them very safe, as Resolution Bay, in Tahuata; and the three harbours, Anna Maria, or Taio-Hoae, Cheveme, or Comptroller's Bay, and Hapoa, or Tshitshagoff, in Nookahivah.

The climate is rather warm. The thermometer seldom descends below 61° or 62°. In May it ranges between 77° and 79°, and in June about 80°. Winter is characterised by abundant showers of rain. Sometimes however not a drop of rain falls for nine or ten months, the consequence of which is famine. The prevailing wind is the eastern trade-wind, which blows strongest in autumn. The south-east wind prevails in winter, and the north wind is frequent in summer. West and north-west winds are nearly unknown. Thunder-storms are of rare occurrence. The climate is very healthy, and diseases are rare. The fruit-trees are chiefly the cocoa-nut, bread-fruit, and papaw (*Carica papaya*). The inhabitants also cultivate bananas, plantains, sweet-potatoes, and taro (*Caladium sagittifolium*). From the bark of the mulberry-tree (*Morus papyrifera*) they make their garments. The wild cotton is superior to that which is cultivated in some other islands, and the sugar-cane is abundant, large in growth, and of excellent quality. Tobacco is extensively cultivated. There are no animals except hogs and rats. Fish is abundant, and constitutes one of the most common articles of food.

The inhabitants belong to the same race that peopled the Society and Sandwich Islands, of which their language and bodily conformation offer undoubted proof. Their complexion is of a dark copper, but the women are much lighter than the men. Many of the navigators speak of their figure in terms of admiration, and consider them as perfect models of symmetry. Langsdorf states that the measures taken on the body of one of their chiefs agreed exactly with those of the Apollo Belvedere. Later travellers do not confirm such statements, and it seems that the difference between individuals is greater here than in most other countries, and that the men vary in height between four feet ten inches and six feet. They have carried the art of tatooing the body to a greater degree of perfection than any nation, the bodies of distinguished persons being covered all over with regular figures of a very tasteful pattern. The people are cannibals. They eat both the bodies of their enemies, who are killed in battle, and also other persons, at the instigation of their priests, or rather sorcerers. In time of famine, which occasionally happens, women and children are killed for food. They have chiefs, but they are without authority. Their sorcerers have acquired a great influence over them, as they believe in spirits, who punish those who transgress what has been determined by the sorcerers. They have always shown themselves very friendly towards Europeans, but the missionaries who have been among them have not been successful in their labours.

(Cook's *Second Voyage*; Krusenstern's *Voyage*; Langsdorf's *Voyages and Travels in various Parts of the World*; Waldegrave and Bennett, in *London Geogr. Journal*, vols. iii. and vii.)

MARQUIS, a title of honour used in England and on the Continent. Persons who have this title in England are the second in the five orders of English nobility. The dukes only are above them. In parliament all peers have the same privileges, by whatever title they are known. Marquises in England have this privilege above earls, that their younger sons are addressed as 'my lord,' as Lord Henry Petty, Lord John Thynne.

All titles of honour seem to have been originally the names of important offices, or to have denoted persons invested with a peculiar political character. Marquis is generally supposed, as we think justly, though other origins have been suggested, to have designated originally persons who had the care of the marches of a country. [MARCHES.] In Germany the corresponding term is *markgraf* (margrave), which seems to be 'lord of the marches.'

There were no English marquises before the reign of Richard II. In the reign of Edward III. a foreign marquis, the marquis of Juliers, was made an English peer with the title of earl of Cambridge, and this circumstance probably suggested to King Richard the introduction of this new order of nobility. The person on whom it was conferred was his great favourite Robert de Vere, earl of Oxford, who was created duke of Ireland and marquis of Dublin in 1385. But the title had no long continuance in him, for three years after he was attainted and his honours forfeited.

In 1397 one of the illegitimate sons of John of Gaunt was created marquis of Dorset, but he was soon deprived of the title, and his son had only the earldom of Somerset. The title of marquis of Dorset was however revived in the same family in 1443, when also William de la Pole was made marquis of Suffolk.

In 1470 John Nevil, earl of Northumberland, brother to Richard Nevil, earl of Warwick, the king-maker, was made marquis Montacute, but he was soon after slain at the battle of Barnet, and the title became lost.

In 1475 Thomas Grey, earl of Huntingdon, son to the queen of King Edward IV. by her former husband, was made marquis of Dorset; and in 1489 William Berkeley, earl of Nottingham, was made marquis of Berkeley. Henry VIII. made Henry Courtenay, earl of Devonshire, marquis of Exeter; and he made Anne Boleyn, a little before his marriage with her, marchioness of Pembroke. William

Parr, earl of Essex, brother of Queen Catherine Parr, was created marquis of Northampton by King Edward VI.; and William Powlett, earl of Wiltshire, marquis of Winchester.

All these titles had become extinct in 1571, except that of marquis of Winchester. This title still continues in the male representative of the original grantee, though for a century or more it was little heard of, being lost in the superior title of duke of Bolton.

Queen Elizabeth made no new marquis, nor did King James I. till the fifteenth year of his reign, when his great favourite George Villiers was created marquis of Buckingham. Charles I. advanced the earls of Hertford, Worcester, and Newcastle to be marquises of those places; and Henry Pierrepoint, earl of Kingston, was made marquis of Dorchester.

Charles II. advanced the earl of Halifax to be marquis of Halifax in 1682, and James II. made the earl of Powis marquis of Powis in 1687.

A new practice in relation to this title was introduced at the Revolution. This was the granting of the title of marquis as a second title when a dukedom was conferred. Thus when Schomberg was made duke of Schomberg he was made also marquis of Harwich; when the earl of Shrewsbury was made duke of Shrewsbury he was also made marquis of Alton: and when the earl of Bedford was made duke of Bedford he was also made marquis of Tavistock. There were many other creations of this kind in the reign of William III., and several of marquisates only. It is not intended to name all the instances, either in this or the subsequent reigns. Of the existing dukes eleven have marquisates in the second title, which is borne by the eldest son during the life of the father.

The only marquis who sits in the House of Peers as a marquis, and whose title dates before the reign of George III., is the marquis of Winchester. The other marquises are all of recent creation, though most of them are old peers under inferior titles.

The title seems not to have been known in Scotland till 1599, when marquises of Huntley and Hamilton were created.

MARRIAGE is a contract by which a man and a woman enter into a mutual engagement, in the form prescribed by the laws of the country in which they reside, to live together as husband and wife during the remainder of their lives.

Marriage is treated as a civil contract even by those Christians who regard it as a sacrament, and as typical of the union between Christ and the church. The religious character of the transaction does not attach until there has been a complete civil contract, binding according to the laws of the country in which the marriage is contracted. The authority of the sovereign power in regulating and prohibiting marriages is therefore not affected by the superinduced religious character.

Among Protestants marriage has ceased to be regarded as a sacrament, yet in most Protestant countries the entrance into the marriage state has continued to be accompanied with religious observances. These are not however essential to the constitution of a valid marriage, any further than the sovereign power may have chosen to annex them to, and incorporate them with, the civil contract.

After the establishment of Christianity, in order to avoid the scandal of persons living together who were not known to be married, and also to secure and perpetuate the evidence of marriage, where really contracted, it became usual to make the marriage promise in the presence of the assembled people, and to obtain at the same time the blessing of the priest upon their union, except when one of the parties had been married before, in which case no nuptial benediction was antiently pronounced, the benediction once received by one party being considered sufficient to hallow the union as to both, unless by the distinction it was intended to intimate that second marriages, though tolerated, were not sanctioned by the church. So late however as the twelfth century, in a decretal epistle of Alexander III. to the bishop of Norwich, the pope says, 'We understand from your letter that a man and woman mutually accepted one another without the presence of any priest, and without the observance of those solemnities which the Anglican church is wont to observe, and that before consummation of this marriage he had contracted marriage with another woman, and consummated that marriage. We think right to answer, that if the man and the first woman accepted one another de præsenti, saying one to another, "I accept thee as mine, and I accept thee as mine," although the wonted solemnities were not observed, and although the first marriage was not consummated, yet the woman ought to be restored to her husband; since after such consent he neither should nor could marry another.'

Private marriages, designated *clandestine* marriages by the clergy, continued to be valid till the Council of Trent, which, after anathematizing those who should say that private marriages theretofore contracted by the sole consent of the parties were void, decreed, contrary to the opinion of 56 prelates, that thenceforward all marriages not contracted in the presence of a priest and two or three witnesses should be void. This decree, being considered as a usurpation upon the rights of the sovereign power, which alone can prescribe whether any and what formalities shall be required to be added to the consent of the parties in order to constitute a valid marriage, has never been received in France and some other Catholic countries.

A marriage was clandestine if contracted otherwise than in public, that is, in facie ecclesiæ; and it was called an *irregular* marriage if it was clandestine, or if, though not clandestine, it was contracted without the benediction of a priest in the form prescribed by the rubric, the intervention of a priest having latterly been required in all cases, even though one of the parties were a widower or a widow. Clandestinity and irregularity subjected the parties to ecclesiastical censures, but did not affect the validity of the marriage.

The decrees of the council of Trent had no force in England. A marriage by mere consent of parties, until the passing of the Marriage Act in 1753, constituted a binding engagement; though if application were made to the ecclesiastical courts for letters of administration, &c., under a title derived through such irregular marriage, those courts sometimes showed their resentment of the irregularity by refusing their assistance, more especially where the noncompliance with the usual formalities could be traced to disaffection to the Established Church. What the formalities required by the Church before the Marriage Acts were, it is now immaterial to consider. Such of them as are not incorporated into any of the Marriage Acts, are now of no force for any purpose.

To constitute a valid marriage, as well before as since the Marriage Acts, it is necessary, 1st, that there should be two persons capable of standing in the relation of husband and wife to each other; 2ndly, that they should be willing to stand in that relation; and 3rdly, that they should have contracted with one another to stand in that relation.

1. The capacity of standing in the relation of husband and wife implies that at the time of the contract there should be no natural or legal disability. Total and permanent disability on either side to consummate marriage will render the contract void. Temporary disability from disease does not affect the validity of a marriage. Temporary disability from defect of age does not invalidate the marriage, but it leaves the party or parties at liberty to avoid or to confirm such premature union on attaining the age of consent, which for males is 14, and for females 12. Before the abolition of feudal tenures, when the lords were entitled to sell the marriages of their male and female wards, infantine marriages were very common, fathers being anxious to prevent wives and husbands from being forced upon their children after their death, and lords being eager, either to secure the prize for their own family, or to realise the profit resulting from a sale. A person who is already married is under a legal disability to contract a second marriage whilst the first wife or husband is alive; and although there may have been the strongest grounds for believing that the first wife or husband was dead, the children of the second marriage would not in England derive any benefit from the absence of moral guilt in their parents, though in France and some other countries the issue of marriages so contracted, bonâ fide, are treated with greater indulgence.

Near consanguinity or relationship in blood is a legal impediment to marriage. The degree of nearness which shall disable parties from uniting in marriage varies in different countries, and has varied at different periods in our own.

This impediment is founded not only upon the moral but upon the physical constitution of man. The purity of domestic intercourse, the sanctity of affection with which the family circle is now united, would be at an end if matrimonial connexions could be formed among its members;

and even with the present restrictions intermarriages in families are frequently productive of the most injurious consequences in respect of mental and bodily health.

Affinity or relationship by marriage is an impediment arising out of moral considerations alone. The extent to which this impediment has been carried has also varied.

The impediment to marriage arising out of consanguinity applies in the same degree to illegitimate as to legitimate relations, and the impediment resulting from affinity is created by illicit connexion as well as by marriage. The Council of Trent restricted the impediment of affinity arising out of illicit connexion to the second degree.

2. Each party must have the will to contract marriage with the other. An idiot therefore, who cannot understand the nature of the conjugal relation, is incapable of contracting marriage. So is a lunatic, except during a lucid interval. But however absurd it may appear, children are presumed to have sufficient intelligence to understand the nature of the marriage engagement at seven; and though the contract is not absolutely binding upon them until they reach the age of consent, still the marriage of a child above the age of seven would prevent its forming a second marriage until the age of consent, as until that age it cannot dissent from the first marriage.

3. There must be an actual contract of marriage. This, at common law, might be by words of present contract, which would, without more, constitute a perfect marriage,—or by words of future contract, followed by cohabitation.

The unlimited freedom of marriage was first broken in upon in England by the Marriage Act of 1753 (26 Geo. II., c. 33), the principal provisions of which form the basis of the law as it now stands. Many of these provisions are taken from the canon law, an observance of which was, before this statute, necessary to constitute a *regular* marriage, though a marriage contracted without them was *valid*.

The restrictions upon the common-law freedom of marriage are now embodied in two statutes.

The 4 Geo. IV., c. 76, contains the following provisions: Banns of matrimony are to be published in the church, or a public chapel in which banns are allowed to be published, of the parish or chapelry wherein each of the parties dwells, immediately after the second lesson of morning service, or of evening service if there be no morning service, upon three Sundays preceding the solemnization (s. 2). Notice of the names of the parties, their place of abode, and the time during which they have dwelt there, is to be delivered to the minister seven days before the first publication (s. 7). Banns are to be republished on three Sundays, if marriage do not take place within three months after publication completed (s. 9). No licence of marriage (that is, dispensation from the obligation to publish banns) is to be granted to solemnize marriage in any church or chapel not belonging to the parish or chapelry within which the usual place of abode of one of the parties has been for fifteen days immediately before the granting of the licence (s. 10). Extra-parochial places are to be taken to belong to the parish or chapelry next adjoining (s. 12). Upon obtaining a licence, one of the parties must swear that he or she believes that there is no impediment of kindred or alliance (consanguinity or affinity), or of any other lawful cause, nor any suit commenced in any ecclesiastical court, to hinder the marriage, and that one of the parties has, for fifteen days immediately preceding, had his or her usual place of abode within the parish or chapelry; and where either of the parties, not being a widower or widow, is under the age of twenty-one, that the consent of the person or persons whose consent is required by that act has been obtained, or that there is no person having authority to give such consent (s. 14). The father, if living, of any party under twenty-one, not being a widower or widow, or, if the father be dead, the guardian or guardians of the person of such party, or one of them, and in case there be no guardian, then the mother of such party if unmarried, and if there be no mother unmarried, then the guardian or one of the guardians of the person appointed by the Court of Chancery, has authority to give consent to the marriage of such party; and such consent is required, unless there be no person authorized to give it (s. 16). In case of the father, guardian, or mother being *non compos mentis*, or beyond sea, or unreasonably or from undue motives refusing or withholding consent, any person desirous of marrying may petition the lord-chancellor, master of the rolls, or vice-chancellor; and in case the marriage proposed shall, on examination, appear to be proper, the lord-chancellor, &c., may judicially declare the same to be so; and such declaration shall be equivalent to consent of the father, &c. (s. 17). If a marriage be not had within three months after licence, marriage cannot be solemnized without a new licence or banns (s. 19). The archbishop of Canterbury is authorized to grant special licences to marry at any convenient time or place (s. 20). If any persons, knowingly and wilfully, intermarry in any other place than a church or such public chapel, unless by special licence, or, knowingly and wilfully, intermarry without the publication of banns and licence, or, knowingly and wilfully, consent to the solemnization of such marriage by a person not being in holy orders, the marriage is null and void (s. 22). (It has been held, that in order to invalidate a marriage under this section, both parties must know the irregularity of the proceeding.) When a marriage is solemnized between parties, both or one of them being under age, by false oath or fraud, the marriage is valid, but the guilty party is to forfeit all property accruing from the marriage (s. 23). After the solemnization of any marriage by banns or licence, no proof can be required of actual dwelling or usual place of abode, nor can any evidence be received to prove the contrary (s. 26). Marriages are to be solemnized in the presence of two witnesses besides the minister, and registered.

The principal provisions of 6 & 7 Wm. IV., c. 85, which was passed chiefly in ease of those who scrupled at joining in the services of the Established Church, are these:—Marriages may be solemnized on production of the registrar's certificate, under the provisions of that act, in like manner as after publication of banns (s. 1). In every case of marriage intended to be solemnized according to the rites of the Church of England, unless by licence or special licence, or after publication of banns, and in every case of marriage intended to be solemnized according to the usages of the Quakers or Jews, or according to any form authorised by that act, one of the parties is to give notice, according to the form set out in the act, to the superintendent registrar of the district or each of the districts within which the parties have dwelt for seven days then next preceding, stating the name and surname, and the profession or condition, and the dwelling-place of each, and the time (not less than seven days) during which each has dwelt therein, and the church or building in which the marriage is to be solemnized (s. 4).

After the expiration of seven days, if the marriage is to be solemnized by licence (that is, from the surrogate, or officer of the ecclesiastical court), or of twenty-one days, if without licence, the superintendent registrar, upon request, is to issue a certificate, provided no lawful impediment be shown, stating the particulars set forth in the notice, the day on which it was entered, that the full period of seven days or of twenty-one days has elapsed since the entry of such notice, and that the issue of such certificate has not been forbidden by any authorised person (s. 7). (This provision does not apply to marriages by licence celebrated according to the rites of the Church of England.) The like consent is required to a marriage solemnized by licence, as would have been required to marriages by licence before the passing of the act (that is, by 4 Geo. IV., c. 76, s. 16 & 17); and every person whose consent to a marriage by licence is required by law is authorised to forbid the issue of the superintendent registrar's certificate (s. 10). Every superintendent registrar may grant licences for marriage in any building registered within any district under his superintendence, or in his office (s. 11). Before any licence for marriage can be granted by a superintendent registrar, one of the parties must appear personally before him, and must, in case the notice of the intended marriage has not been given to the same superintendent registrar, deliver to him the certificate of the superintendent registrar or registrars to whom such notice has been given; and such parties must make oath, affirmation, or declaration, that he or she believes that there is not any impediment of kindred or alliance, or other lawful hindrance, to the marriage, and that one of the parties has for fifteen days immediately before the day of the grant of the licence (or rather the day of the making of the oath, &c.), had his or her usual place of abode within the district in which such marriage is to be solemnized; and where either party, not being a widower or widow, is under twenty-one, that the consent of the person or persons whose consent to such marriage is required by law has been obtained thereto, or that there is no person having authority to give such consent (s. 12). No marriage after notice, unless by virtue of a licence by the superintendent registrar, is to be solemnized or registered until after the expiration of twenty-one days after entry of notice, and no marriage is to be solemnized by the licence of any superintendent registrar, or registered, until after the expiration of seven days after the day of the entry of notice (s. 14). Whenever a marriage is not had within three calendar months after notice entered by the superintendent registrar, the notice and certificate, and any licence granted thereupon, and all other proceedings, become utterly void; and no person can proceed to solemnize the marriage, nor can any registrar register the same, until new notice, entry, and certificate (s. 15). The certificate of the superintendent or (superintendents) is to be delivered to the officiating minister, if the marriage is to be solemnized according to the rites of the Church of England; and such certificate or licence is to be delivered to the registering officer of Quakers for the place where the marriage is solemnized, if the same shall be solemnized according to their usages; or to the officer of a synagogue by whom the marriage is registered, if to be solemnized according to the usages of persons professing the Jewish religion; and in all other cases it is to be delivered to the registrar present at the marriage (s. 16).

Any proprietor, or trustee, of a separate building, certified, according to law, as a place of religious worship, may apply to the superintendent registrar, in order that such building may be registered for solemnizing marriages therein; and in such cases he is to deliver to the superintendent registrar a certificate signed in duplicate by twenty householders, that such building has been used by them during one year as their usual place of public religious worship, and that they are desirous that the place shall be registered; each of which certificates is to be countersigned by the proprietor or trustee by whom the same is to be delivered, and the superintendent registrar is to send both certificates to the registrar-general, who is to register such building accordingly, and indorse on both certificates the date of the registry, and to keep one certificate with the other records of the general register office, and to return the other certificate to the superintendent registrar, who is to keep the same with the other records of his office; and the superintendent registrar is to enter the date of the registry of such building, and is to give a certificate of such registry under his hand, on parchment or vellum, to the proprietor or trustee by whom the certificates are countersigned, and is to give public notice of the registry thereof, by advertisement in some newspaper circulating within the county and in the 'London Gazette' (s. 18).

After the expiration of the twenty-one days, or of seven days, if the marriage is by licence (that is, from the surrogate), it may be solemnized in the registered building stated in the notice, between and by the parties described in the notice and certificate according to such form and ceremony as they may see fit to adopt· every such marriage to be solemnized with open doors between eight and twelve in the forenoon, in the presence of some registrar of the district in which the building is situate, and of two witnesses.

In some part of the ceremony, and in the presence of registrar and witnesses, each of the parties is to declare—

> 'I do solemnly declare, that I know not of any lawful impediment why I, A. B., may not be joined in matrimony to C. D'

And each of the parties is to say to the other—

> 'I call upon these persons here present, to witness that I, A. B., do take thee, C. D., to be my lawful wedded wife (or husband).'

Provided also, that there be no lawful impediment to the marriage of such parties (s. 20). Persons who object to marry in any such registered building may, after due notice and certificate issued, contract and solemnize marriage at the office of the superintendent registrar, and in his presence and in that of some registrar of the district, and of two witnesses, with open doors, and between the hours aforesaid, making the declaration and using the form of words as above (s. 21). After any marriage solemnized, it is not necessary, in support of such marriage, to give proof of the actual dwelling of either of the parties previous to the marriage within the district for the time required by the act, or of the consent of any person whose consent is required; nor is evidence admissible to prove the contrary in any suit touching the validity of such marriage (s. 25) The registrar before whom any marriage is solemnized according to the provisions of this act may ask of the parties to be married the several particulars required to be registered touching such marriage (s. 36). Every person knowingly and wilfully making any false declaration, or signing any false notice or certificate required by this act, for the purpose of procuring any marriage, and every person forbidding the issue of any superintendent registrar's certificate by falsely representing himself or herself to be a person whose consent to such marriage is required by law, knowing such representation to be false, is to suffer the penalties of perjury (s. 38). If any person knowingly and wilfully intermarry under the provisions of this act,—in any place other than the church, chapel, registered building, or office, or place specified in the notice and certificate,—or without due notice to the superintendent registrar,—or without certificate of notice duly issued,—or without licence, in case a licence is necessary,—or in the absence of a registrar, where the presence of a registrar or superintendent registrar is necessary, the marriage of such persons, except in certain excepted cases, is null and void (s. 42); as under 4 Geo. IV., c. 76, s. 22, a marriage would not be void unless *both* parties knowingly and wilfully concurred in marrying contrary to the provisions of the 42nd section. If any valid marriage be had under the provisions of this act by means of any wilfully false notice, certificate, or declaration made by either party to such marriage, as to any matters to which a notice, certificate, or declaration is required, the attorney-general or solicitor-general may sue for a forfeiture of all estate and interest in any property accruing to the offending party by such marriage (s. 43). Consent to marriage may be withdrawn upon good reason; but it would rather appear that this cannot be done merely because the parent or guardian has changed his mind. The question of consent is not however of such vital importance as under the first Marriage Act (26 Geo. II., c. 33, s. 11), which made marriages without consent of parents, &c. absolutely void. Under 4 Geo. IV., c. 76, s. 23, and 6 & 7 Wm. IV., c. 85, s. 43, a false statement as to consent subjects the fraudulent party to the penalties of perjury, and to a forfeiture of all estate and interest in any properties accruing by the marriage, but leaves the marriage itself in full force.

These statutes do not extend to marriages contracted out of England, or to marriages of the royal family, which are regulated by a particular statute, 12 George III., c. 11.

Before 1835 marriages within the prohibited degrees of consanguinity and affinity were valid until annulled by a declaratory sentence of the ecclesiastical court, after which they became void ab initio, and the issue of such marriages were, by such sentence, rendered illegitimate; and the law is still so with respect to personal incapacity existing at the time of the contract. But as the ecclesiastical court could, professedly, only proceed *pro sulute animæ*, and its authority to annul an incestuous marriage was founded upon the duty of putting a stop to the incestuous intercourse, the power of annulling the marriage ceased upon the death of either of the parties. The validity of such marriage, and the legitimacy of the issue, depended therefore upon the contingency of a suit being instituted and a sentence pronounced, during the joint lives of the husband and wife. But now, by 5 and 6 Will. IV., c. 54, all marriages thereafter celebrated between persons within the prohibited degrees of consanguinity or affinity are absolutely void to all intents and purposes. And, even at common law, a marriage contracted while there is a former wife or husband alive is ipso facto void, without any declaratory sentence.

Generally speaking, a marriage, valid according to the law of the country in which it was contracted, is valid in every other country. This rule is however subject to some exceptions, as where marriages, contracted according to the law of the country (*lex loci*), are considered in the courts in which their validity happens to be contested, as contracted in violation of some principle of natural religion or morality, or as where, in Persia or Turkey, a man marries a second wife in the lifetime of the first.

A constitution of the emperor Constantine, [illegible] in 476 by the emperor Zeno (*Cod.*, lib. 5, tit. 27, [illegible] the husband of a concubina who had [illegible] without having had any child ex justis [illegible] concubina to the dignity of justa uxor, [illegible] those children the privilege of children [illegible] tiis, though actually born ex concubi[illegible] tini, qui venerandâ Christianorum [illegible] imperium, super *ingenuis* conc[illegible] filiis quinetiam ex iisdem, vel ante matrimonium, vel postea progenitis, suis ac legitimis habendis, sacratissimam constitutionem renovantes, jubemus eos, qui ante hanc legem, ingenuarum mulierum nuptiis minimè intercedentibus, electo contubernio, cujuslibet sexus filios procreaverint: quibus nulla videlicet uxor est, nulla ex justo matrimonio legitima proles suscepta: si voluerint eas uxores ducere, quæ antea fuerant concubinæ tum conjugium legitimum cum hujusmodi mulieribus ingenuis (ut dictum est) posse contrahere, quam filios utriusque sexus ex earundem mulierum priore contubernio procreatos, mox postquam nuptiæ cum matribus eorum fuerint celebratæ, suos patri, et in potestate fieri: et cum his, qui postea ex eodem matrimonio suscepti fuerint, vel solos (si nullus alius deinde nascatur) tam ex testamento volentibus patribus etiam ex integro succedere, quam ab intestato petere hereditatem paternam, &c.'

This was carried still further when marriage was invested with a religious character. Its efficacy as a sacrament was regarded as so powerful, as to have a retrospective operation upon children born at a time when there was no semblance or intention of marriage of any kind, provided that at the time of the birth there existed no impediment to the marriage of the parents. Alexander III., who filled the papal chair from 1159 to 1181, pronounces that 'Tanta est vis matrimonii, ut qui antea sunt geniti, post contractum matrimonium, legitimi habeantur.' *Extravag.*, cap. 6, 'Qui filii sunt legit.' (Pothier, *Traité du Contrat de Mariage.*) This modification of the law of legitimacy, though frequently recommended by the clergy, was never adopted in England by the laity. It is however the law of Scotland and of France, and of most other Catholic countries.

MARRIAGE, ROMAN. The right conception of the Roman institution of marriage and of its legal consequences is essential to enable us to approximate to a right understanding of the old Roman polity.

Children were in the power of their father [EMANCIPATIO] only when they were the offspring of a legal marriage (justæ nuptiæ, or justum matrimonium). The cases of legitimation and adoption need not be considered here. To constitute such a legal marriage there must be between the parties *connubium*, the nature of which condition is best explained by an example:—Between a Roman citizen and the daughter of a Roman citizen there was *connubium*, and as a consequence the children of such marriage were Roman citizens, and in the power of their father. Between a Roman citizen and a female slave (ancilla) there was no *connubium*, and consequently the children which sprung from such a union were not Roman citizens. Whenever there was no *connubium*, the children followed the condition of the mother: when there was *connubium*, they followed the condition of the father. Various degrees of consanguinity, as the relation of parent and child, prevented *connubium* between parties in such a relation. After the emperor Claudius had married Agrippina, his brother's daughter, such relationship was no longer an impediment to a legal marriage; but the licence was carried no further than the terms of the decretum of the senate warranted, and the marriage of an uncle with his sister's daughter remained, as before, an illegal union. (Tacit., *Annal.*, xii. 7; Gaius, i. s. 62.) Further, to constitute a legal marriage, the two parties must be of sufficient bodily maturity; both parties also must consent, if they are capable of giving a legal consent (sui juris); or if not, their parents must consent.

The ceremonial parts of the marriage were of three kinds, by any one of which the wife was said to come into the hand of the husband (in manum), and to occupy the legal relation of a daughter. A woman who lived for one year with a man without interruption became his wife by virtue of this cohabitation (usus). As in the case of all moveables, by the laws of the Twelve Tables, one year's enjoyment of a thing transferred the ownership of it, so by one year's uninterrupted cohabitation the husband acquired that interest in the wife which was the result of complete marriage. The Twelve Tables provided that if the wife wished to avoid the legal effect of this cohabitation, it was only necessary to absent herself from her husband for three nights during the year, which would be a sufficient legal interruption to the usus. In the time of Gaius this part of the old law had been partly abolished by enactments, and had partly fallen into disuse.

The Confarreatio, so called from the use of a loaf of bread on the occasion, appears to have been of the nature of a religious ceremony, and it existed in the time of Gaius. It appears that certain offices, such as that of Flamen Dialis, could be held only by those who were born of parents who had been married by the ceremony of Confarreatio. (Gaius, i. 112; Tacit., *Ann.*, iv. 16.)

The Coemptio was, in form, a sale (mancipatio) before five witnesses. [MANCIPIUM.] The Coemptio might be made either between a woman and her intended husband, in which case she became, in contemplation of law, his daughter, or between a woman and a stranger (fiduciæ causa), which was a necessary legal process in case a woman wished to change one guardian for another, or to acquire the privilege of making a will. For until the senascultum passed in the time of Hadrian no woman could make a testamentary disposition (with the exception of certain privileged persons), unless she had contracted the Coemptio, that is, had been sold, and then resold and manumitted. The Coemptio, being effected by mancipatio, worked a legal change of status (*Dig.*, iv., tit. 5, s. 1), or *diminutio capitis*; and it was the least of the three kinds of *diminutio capitis*, or that by which a person underwent no change in his civil capacity, except the being transferred into another family. (Paulus, *Dig.*, iv., tit. 5, s. 11.) This explanation will render intelligible the passage of Cicero on the testamentary power of women (*Topic.*, 4), taken in connection with Gaius (i., s. 115, &c.). The essays of Hoffmann and Savigny in the 'Zeitschrift für Geschichtliche Rechtswissenschaft,' vol. iii., p. 309, &c., may also be read with advantage.

A gift from husband to wife, or from wife to husband, was void (with some few exceptions). The transaction was the same as if nothing had been done. The Donatio mortis causâ, or divortii caussâ, in contemplation of death, or in consideration of divorce, was a valid gift.

There could be no *dos* (marriage portion), unless there was justum matrimonium. The term *dos* comprehended both what the wife brought to the husband on her own account, and what was given or contracted to be given by any other person, in consideration and for the purposes of the marriage. (*Dig.*, xxiii., tit. 3, s. 76.) When the *dos* came from the wife's father, it was called *profecticia*, but when from any other person, *adventicia*. It was a general rule that the *dos adventicia* remained with the husband, unless there was some agreement to the contrary, in which case it was called *dos recepticia*. What came into the husband's possession, not as *dos*, was included in the term Parapherna (*παράφερνα*), or Paraphernalia, and did not become the property of the husband. All kinds of property could be the subject of *dos*. If they were things that could be estimated by number, weight, and measure (res fungibiles), the husband took them, subject to the liability, in case of a dissolution of the marriage, of restoring things to the same number, weight, and measure. Things given as *dos* might be valued or not valued: in case they were valued, the complete ownership of them passed to the husband, inasmuch as the valuation was in the nature of a sale, and the husband could dispose of the things as he pleased, subject only to the liability of restoring their value, in case of a dissolution of the marriage. If the things were not valued, and any loss ensued, without the fault or culpable neglect of the husband, the loss fell on the wife. In the case of things which were not fungibiles or not valued, the ownership during the marriage might be considered as in the husband, and as returning to the wife on the dissolution of the marriage. In such a case the husband could manage the wife's property as his own; he enjoyed the profits of it during the marriage, and could sell it. With some exceptions however he could not sell or dispose of the wife's immoveable property which was included in the *dos* (dotale praedium). (Gaius, ii., s. 63; *Instit.*, ii., tit. 8.) The portion became the husband's on the solemnization of the marriage, and he had the profits of it during the marriage. In the case of divorce the portion, or a part of it, according to circumstances, was restored. In case the wife died during the subsistence of a marriage, part returned to her father, and part remained to the children of the marriage, if any; but it might, by the terms of the marriage contract, become the husband's, even if there were no children of the marriage. As to the portion of the wife, whatever might have been originally the rights of the husband over it by virtue of the marriage, it was in later times the subject of the express stipulations of the marriage settlement. The questions of law which arose on the subject of the *dos* were numerous and sometimes difficult.

In enumerating the modes by which a man may acquire property *per universitatem*, Gaius mentions marriage, by which a woman comes *in manum viri*, and he observes that all things pass to the husband. The meaning of this passage is perhaps not quite certain; but it is partly explained by what has been already said.

(*Dig.* 23, tit. 3, 'De Jure Dotium;' tit. 5, 'De Fundo dotali;' Ulpian, *Frag.* vi., 'De Dotibus;' Thibaut, *System des Pandekten-Rechts.*)

MARROW, or **MEDULLA**, is the fat contained in the osseous tubes and cells of the bones. [BONE.] It consists of an oily fluid, contained in minute vesicles, which are usually collected into bunches and enclosed in spaces surrounded by bony walls. It is most abundant in the cavities of the long bones, and in the spongy tissue of their articular extremities, and of the short rounded bones.

Spinal marrow and medulla spinalis are names sometimes applied to the spinal chord. [NERVES.]

MARRU'BIUM VULGA'RE (White Horehound), a biennial or perennial herbaceous plant, common by roadsides, the officinal part of which is the leaves; these are to be collected without the stalks. They are of a whitish-grey woolly appearance, possessed of a faint odour, which becomes less by drying, and a bitter sharp taste. Ten pounds of leaves yield four pounds of extract. Their chief constituents are a bitter extractive, with a volatile oil, and probably some astringent matter.

White horehound, when young, is apt to be confounded with many other labiate plants, particularly the Ballota nigra, or black horehound, which possesses a disagreeable odour. The medicinal properties of horehound are very insignificant, being demulcent, slightly tonic, and astringent. As a popular remedy, it enjoys great favour in many pulmonary complaints; but the preparations vended under the name of horehound often contain more efficient ingredients, to which they owe their success.

MARS, the planet which comes next to the earth, in order of distance from the sun, is a brilliant star of a slightly red tint. On examination in a telescope, this colour is found to belong to parts of the surface of the planet which have been conjectured to be land; the rest, which appears somewhat green, being supposed to be sea. Certain white spots, which appear at each pole after the winter of its hemisphere, and disappear during its summer, have been conjectured to be snow. The apparent diameter of Mars varies from 3″·6 to 18″·28, being 6″·29 when the planet is at its mean distance from the earth. The real diameter is ·517 of that of the earth, or about 4100 miles. Its bulk is ·1386 of that of the earth, and its mass is ·0000003927 of that of the sun, or about the 2546000th part.

The planet revolves on its axis in $24^h\ 39^m\ 21^s{\cdot}3$, and the axis is inclined to the ecliptic 30° 18′ 10″·8. Its light and heat are 43 per cent. of those of the earth.

Elements of the Orbit of Mars.

Epoch 1799, December 31, 12^h mean astronomical time at Seeberg.

Semiaxis major 1·5236923, that of the earth being assumed as the unit.

Excentricity ·0933070; its secular increase (or increase in 100 years) ·000090176.

Inclination of the orbit to the ecliptic 1° 51′ 6″·2; its secular alteration insensible.

Longitudes from the mean equinox of the epoch (1.) of the ascending node 47° 59′ 38″·4; its secular increase (combined with the precession) 2500″; (2.) of the perihelion 332° 22′ 51″; its secular increase (combined with the precession) 6582″; (3.) of the planet (mean) 232° 33′ 23″·2.

Mean sidereal motion in one mean solar day, 31′ 26″·655; in 365¼ days 689100″·739; sidereal revolution 686·9796458 mean solar days.

MARS, or **MAVORS** (called *Mamers* in the Oscan language), the god of war among the Romans, generally considered as corresponding to the Greek *Ares*. He was also called Marspater or Marspiter (Gell., v. 12), and was worshipped in peace under the name of Quirinus, and in war under that of Gradivus. There was a temple in Rome sacred to Quirinus, and another outside the city, in which he was worshipped under the name of Gradivus, on the Appian Way, near the gate Capena (Servius on *Æneid*, i. 296). According to tradition, Romulus was the son of Mars, by Rea Silvia; and it was perhaps owing to his being the tutelar god of the Romans that the husbandmen were accustomed, according to Cato (*De Re Rust.*, c. 141), to present their prayers to this deity, when they purified their fields by performing the sacrifice called *suovetaurilia*, which consisted of a pig, a sheep, and a bull. He is also called by Cato, Mars Silvanus (c. 83). According to a principle in Roman mythology, by which a male and a female deity are always supposed to preside over the same object of fear or desire, the Romans had a goddess of war called BELLONA.

A round shield (*ancile*), which was supposed to have been the shield of Mars, is said to have fallen from heaven during the reign of Numa, and was entrusted to the care of the Salii, the priests of Mars. Eleven other shields were made like it, in order that it might not be stolen.

The first month (Martius) of the old Roman year, which consisted of ten months only, derived its name from this god.

Mars is generally represented with a beard, but in other respects like the Greek Ares, and is frequently placed in the same group with Rea Silvia. (Müller, *Archæologie der Kunst*, p. 492.) For the Greek god of war, see ARES.

MARSA'LA, a town at the western extremity of Sicily, built near the site of the antient Lilybœum, the port of which is filled up. There is however good anchorage, sheltered by a small island which lies off the coast, and which is mentioned in the history of the siege of Lilybœum by the Romans.

The present town of Marsala, which was built by the Saracens, contains about 10,000 inhabitants, and belongs to the intendenza or province of Trapani. [TRAPANI.] The country around produces very good white wine, which is prepared for exportation by an English mercantile house established there, and is known by the name of Marsala. It is exported in great quantities to Malta, and also to England. There are very few remains of antiquity, except some traces of former aqueducts and tombs scattered about the country.

MARSAN, a subdivision of Gascogne, in France, now included in the department of Landes. Mont de Marsan was its capital. [FRANCE; GUIENNE ET GASCOGNE; LANDES.]

MARSDEN, WILLIAM, a distinguished Oriental scholar, was born in Dublin, on the 16th of November, 1754. He was of a Derbyshire family which had settled in Ireland at the end of the reign of Queen Anne. John Marsden, his father, was the son of one of the original settlers, and was established in Dublin as a merchant on a large scale. The subject of this article was his tenth child. After going through the usual course of classical education in the schools of Dublin, he was about to be entered at Trinity College with a view to the church, when his destinies led him to take a very different course. His eldest brother had before proceeded to Bencoolen as a civil servant of the East India Company; and sending home a very favourable account of his prospects, the father was induced to apply for another appointment in the same quarter for William, which proved successful. He was accordingly removed from school, and in the beginning of the year 1771, when he was but 16 years of age, he embarked for India, and arrived at Bencoolen in May of the same year. Here his assiduity, intelligence, and integrity quickly secured to him such distinction as a small establishment and community afforded. He became first sub-secretary, and soon after principal secretary to the government. The duties of these stations were not very laborious, and afforded ample leisure for study and inquiry. Mr. Marsden mastered the vernacular language of the country, the Malay, and at the same time laid in that stock of local knowledge which, being embodied afterwards in his publications, was the foundation of his fame as a writer.

Mr. Marsden's whole stay in Sumatra did not exceed eight years, but how well and diligently he employed this brief period can only be sufficiently appreciated by those who, like the writer of this article, have been engaged in the same pursuits. But he felt that his powers were wasted in the narrow field in which they were exercised, and he determined upon an experiment, usual in such a case as his, that of returning to England to push his fortune. He felt that, at all events, literary leisure, independence, and a congenial climate would be assured to him by this step.

Having this object in view, he quitted Sumatra in the summer of 1779, and in the last days of the same year arrived in England, with good health, but with a very trifling income of a few hundred pounds a year. His first attempt was to procure a small post under the government; but, failing in this, he resolved on a literary retirement, and on supplying the want of wealth by a prudent economy; and if he afterwards abandoned this course, his departure from it cannot be said to have been of his own seeking. Shortly after his return to England he made the acquaintance of the late Sir Joseph Banks, and at his philosophical breakfasts met and acquired the friendship of some of the most eminent men of the day, Solander, Maskelyne, Dalrymple, Rennell, and Herschel. He soon became a Fellow of the Royal Society, and eventually of almost every learned or scientific society of eminence in the kingdom. His literary reputation was insured by the publication, in 1782, of the well-known 'History of Sumatra.' This work, which has come to a third edition, and has been translated into French and German, has maintained its reputation with the public for the long period of 56 years. It has the peculiar impress of Mr. Marsden's mind, strong sense, truthfulness, and caution. In so far as our language at least is concerned, it may be considered as the first book of Oriental travels which, with a thorough and intimate personal knowledge of local details, combines philosophy, science, and a liberal acquaintance with letters. For 14 years after his return to England Mr. Marsden's time was devoted wholly to literature and science; and in this manner it was his fixed intention to have passed the rest of his life. In 1782 he had resisted the temptation of going to India with Admiral Sir Hyde Parker, with the lucrative office of secretary; and, in 1787, the *certainty*, under the auspices of the leading parties at the India House, of becoming an East India Director. In 1795 however, invited by Earl Spencer, on the recommendation of his intimate friend, the celebrated geographer, Major Rennell, he accepted the situation of second secretary; and in due course of time the secretary of the little Bencoolen government, and the author of the 'History of Sumatra' became chief secretary to the British board of Admiralty, with the war salary of 4000*l.* per annum. In this matter however it is evident that Mr. Marsden rather yielded to the advice of his friends than consulted his own inclination. No man at the same time could be better fitted, by diligence, official training, integrity, and general intelligence, to discharge the various functions which he was called upon to perform, and he did so discharge them for a period of 12 years, greatly to his own honour and the public advantage. This period too comprehended the most eventful and glorious in the history of the British navy, for it embraced the victories of Cape St. Vincent, Camperdown, the Nile, and Trafalgar. In 1807 Mr. Marsden, whose health began to suffer severely by the laborious discharge of the very onerous duties of his office, tendered his resignation of the secretaryship to the Admiralty, and retired on a pension of 1500*l.* per annum. The first solid fruits of Mr. Marsden's leisure were the publication, in 1812, of his Grammar and Dictionary of the Malay language, the most difficult, elaborate, and, we may perhaps add, the most likely to endure of his literary labours. A portion of the materials he had of course brought with him from Sumatra, and we find him engaged in the compilation of the Dictionary as far back as 1786. The eventual publication of these works however did not take place until 33 years after he had quitted Sumatra, and, consequently, after he had *ceased* to receive any assistance from native instructors. When we consider therefore the accuracy and erudition by which they are so eminently characterised, we must look upon them as affording the highest proofs of happy industry and acuteness.

After the lapse of twenty-six years, they still continue, as they are likely long to continue, the only standard works on Malayan philology. Translations of them have been made, under the auspices of the Netherland government, both into the French and Dutch languages. In 1817 he published his 'Translation of the celebrated Travels of Marco Polo.' The translation has been made with Mr. Marsden's accustomed accuracy, and is accompanied by a commentary far more valuable than the translation itself. In 1823 he published the first part, and in 1825 the second, of his 'Numismata Orientalia, or Description of Eastern Coins,' a valuable collection of which had fallen into his hands by purchase. This is a work of great care and learning, in which, as well as in some respects in the compilation of the Malayan Dictionary, he had the invaluable assistance of his learned relative Sir Charles Wilkins. In 1832, in his seventy-eighth year, Mr. Marsden published his last work, comprising three Essays, the longest, most elaborate, and important of which is on the Polynesian or East Insular Languages, a subject which had long engaged his attention and was a great favourite with him. He was indeed the first that pointed out the existence of a considerable body of Sanscrit words in all the cultivated Polynesian languages, and also the singular connexion which exists among these languages themselves, extending from Madagascar to Easter Island. In 1831 Mr. Marsden voluntarily relinquished his pension to the public, an act of liberality and generosity which, at the time, had no example, and has had very few since. It met, as it well deserved, the warmest applause of the House of Commons. In 1834, feeling, as he himself says, the increasing infirmities of age, he determined in his life-time to bestow his rich collection of coins and medals and his extensive library of books and Oriental manuscripts in such a manner as would make them most serviceable to the public. The coins and medals he gave to the British Museum, and his library to the newly-founded King's College. In 1833 he had a slight apoplectic attack, and in 1834 and 1835 a second and third. These greatly enfeebled his body, leaving him however in the entire possession of his memory. The final and fatal attack did not take place until the 6th of October, 1836, when, at seven o'clock in the morning, after passing a tranquil night, he gently expired, hardly uttering a groan, in the eighty-second year of a happy, prosperous, and well-spent life. Agreeably to his own directions, he was interred in the cemetery at Kensal Green. In 1807, shortly after quitting the Admiralty, Mr. Marsden married the eldest daughter of his old and intimate friend the late Sir Charles Wilkins; and notwithstanding the great disparity in the ages of the parties, the connexion, which lasted near thirty years, was one of much satisfaction and happiness, the result, on both sides, of exemplary prudence, good sense, and high principle. His widow is the judicious and accomplished editor of the 'Autobiographical Memoir' from which we have extracted this brief account, and which has been printed for private circulation only, and not published.

MARSEILLE, a seaport and city in France, capital of an arrondissement in the department of Bouches du Rhône. It is on the coast of the Mediterranean, 408 to 410 miles in a direct line south-south-east of Paris, or 497 miles by the road through Auxerre, Châlons-sur-Saône, Lyon, Valence, Avignon, and Aix, in 43° 18′ N. lat. and 5° 23′ E. long.

Marseille was founded by the inhabitants of Phocæa (*Φώκαια*), a Greek town which was a member of the Ionian confederation. [IONIA.] The Phocæans founded several colonies in the western part of the Mediterranean, of which Massilia, as the Latins generally wrote it, or Massalia (*Μασσαλία*) according to the usual Greek orthography, was perhaps the earliest, as it certainly was the most important. Two colonies of Phocæans successively established themselves in the place, the first about B.C. 600, while Phocæa was yet flourishing. The leader of this original colony, called by Aristotle ('Η Μασσαλιωτῶν Πολιτεία, quoted in Athenæus Δειπνοσοφισταί, lib. x.) Euxenus (Εὔξενος), having found favour in the eyes of Petta (Πέττα), daughter of Nanus (Νάνος), king of the Segobrigians, a tribe probably of Ligurians (Justin., *Hist.*, c. xliii.), received her in marriage, and also permission to found a city. The circumstances are related, with some variation, by Justin.

The new colony was early involved in hostilities with the native tribes, Ligurian and Celtic, over whom the Massilians obtained several victories, and established new settlements along the coasts, in order to retain them in subjection. The surrounding barbarians acquired from the new settlers some of the arts of civilised life: they learned to prune and train the vine, and to plant the olive. The Massilians had also to contend with the power of the Carthaginians (the commercial rivals of the Greeks in western Europe), whom they defeated in a sea-fight of early but uncertain date. (Thucyd., lib. i., c. 13.)

The second colonization of Massilia took place about B.C. 544, on occasion of the Phocæans quitting their native city to avoid the subjection with which they were threatened by the Persians. Herodotus does not notice the fact of any of these Phocæans settling at Marseille: he says that they sailed to Alalia in Corsica, which was a Phocæan colony, and commenced piracy. The Tyrrheni and Carthaginians uniting against them, a great sea-fight took place, in which the pirates obtained a dear-bought victory. After this battle they left Corsica for Rhegium. (Herod., i. 165-167.)

The Massilian constitution was aristocratic; their laws and their religious rites were similar to those of the Ionians of Asia. The worship of the Ephesian Artemis, or Diana, was cherished with peculiar reverence, both in Massilia itself and in its colonies. The governing body was a senate (*συνέδριον*) of 600 persons, called Timuchi (*τιμοῦχοι*), who were appointed for life. This senate had fifteen presidents (*προεστῶτες*), who formed a sort of committee, by which the ordinary business of the government was managed. Of this committee three persons possessed the chief power. The Timuchi were chosen from among those who had children, and in whose families the right of citizenship had been possessed by three generations. (Strabo, lib. iv.)

The Massilians, like the Phocæans, were a naval people; they had several colonies or posts on the coasts both of Gaul, Spain, and Italy: as Emporium (Ἐμπόρειον), now Ampurias, in Spain; Rhöe Agatha (Ρόη 'Αγαθή), now Agde; Tauroeis (Ταυρόεις), or Tauroentium (Ταυροέντιον), now Tarente, near La Ciotat; Antipolis (Αντίπολις), now Antibes; Olbia (Ολϐία), perhaps the port and castle of Leoube, between Hieres and St. Tropez; and Nicæa (Νίκαια), now Nice. They early and steadily cultivated an alliance with the Romans, which alliance was gradually converted into subjection. In the civil war of Pompey and Cæsar they embraced the party of the former; and receiving L. Domitius, one of his most zealous partisans, within their walls, and appointing him governor of the city, they closed their gates against Cæsar, under pretence of preserving neutrality (B.C. 49). Cæsar, hastening into Spain against Afranius and Petreius, after building and equipping a squadron with marvellous celerity, left his lieutenant C. Trebonius with three legions to carry on the siege, and appointed D. Brutus to command his fleet. In the first naval encounter the townsmen were defeated, with the loss of nine vessels. But the place was well stored with warlike machines; and the townsmen being encouraged by the arrival of L. Nasidienus, who was sent by Pompey to their aid, with a squadron of seventeen ships, they refitted their fleet, and put to sea to join him; but the confederate fleet being defeated by D. Brutus, and an attempt to destroy the machines which Trebonius had prepared for the attack of the city having failed, they were induced to apply for an armistice: this, when obtained, they violated by an attack in which they seriously damaged the works of Trebonius; but these being repaired, they again implored an armistice; and on Cæsar's return from his victory over the Pompeians in Spain, they surrendered to him. Cæsar did not reduce them into entire subjection, but left two legions in garrison while he marched forward into Italy. (Cæs., *De Bell. Civ.*, lib. i. 34-36, 56, 57; ii. 1-16, 22.)

The municipal government of Massilia remained unaltered, but its political independence was virtually overthrown. The attention of the Massilians was now more directed to literature and philosophy, of which indeed they were already diligent cultivators. They had spread through the south of Gaul the knowledge of the Greek written character, which Cæsar found in use among the Helvetii (*De Bell. Gall.*, lib. i., c. 29); and now their city became to the west of Europe what Athens was to the east. The moderate charges and frugal habits of the citizens added to the advantages of the place as a place of study, and the most illustrious of the Roman youth resorted thither. Cicero has recorded in the strongest language the praises of the Massilians (*Orat. pro L. Flacco*, c. 26). Livy has put a high encomium upon them into the mouth of a Rhodian ambassador (lib. xxxvii., 54); and Tacitus (*Agricolæ Vita*, c. 4) has spoken in the same strain. [AGRICOLA.]

For more than three centuries the history of Massilia presents no event of interest. In the troubles which followed the abdication of Diocletian and Maximian, the latter (A.D. 310) attempted to resume the purple at Arles, to the prejudice of the emperor Constantine, his son-in-law; but being baffled in his attempt, fled to Massilia, which he vainly attempted to defend. The city surrendered, or was taken by Constantine, and Maximian became his own executioner.

In the reign of Honorius, Massilia repelled the attempt of the Visigothic king Ataulphus, to take possession (Photii, *Biblioth.*); but it afterwards became the prey of Burgundians, Visigoths, and Franks. It was taken from the Franks by Theodoric the Ostrogoth king of Italy.

Toward the middle of the sixth century Marseille (to which we may now give its modern name), was ceded with the rest of Provence by Vitiges the Ostrogoth to the Franks, in order to secure their alliance against the Eastern emperor Justinian, who had sent Belisarius to conquer Italy. While under the Frankish sceptre the town suffered from the Lombards, who sacked it (A.D. 576), and from the Saracens, who seized it, but were quickly driven from it by the Franks, about the middle of the eighth century. In the division of the empire of Charlemagne among his descendants (A.D. 856), Marseille was included in the kingdom of Provence, under Charles, younger son of the emperor Lothaire; and afterwards it made part of the kingdom of Provence, or Bourgogne Cis-jurane, under Boson (A.D. 879). The union of this kingdom with that of Bourgogne Trans-jurane under Rodolph II. (A.D. 930), and the subsequent acquisition of the united kingdoms by the emperor Conrad le Salic (A.D. 1032), brought Marseille into the condition of a remote dependency of the German empire. During these changes, from the tenth century Marseille was under the immediate dominion of its own viscounts.

The Marseillois appear to have been actively engaged in the Crusades; and in the third Crusade, several armaments sailed from their port. The commerce of the town at this time was great, and the townsmen were in league with some of the great trading cities of Italy for the purposes of trade or of defence. In the beginning of the thirteenth century they freed themselves from feudal subjection to their viscounts and to the counts of Provence, and organised themselves into a municipal republic, under a chief magistrate called the podestat; but in a few years they were deprived of many of their privileges by Charles of Anjou, count of Provence, brother of Louis IX. It was from Marseille that Charles set sail for the conquest of Naples. The troubles which agitated Provence during the reigns of his successors materially diminished the population of Marseille; and as the authority of the emperor in Provence had ceased to exist even in name, the country was exposed to the inroads of the Brigands, who had risen up during the wars of the English in France and the desolation of that kingdom.

In the contest for the sovereignty of Naples and Provence, between the houses of Anjou and those of Durazzo, and subsequently of Aragon, the Marseillois faithfully adhered to the house of Anjou, and rendered signal services to their cause; but in the year 1421 the town was taken by the king of Aragon, and a considerable part of it sacked and burned. It was, upon the retreat of the Aragonese (A.D. 1423), further plundered by marauders from the surrounding country. The town recovered however from this severe blow, and became the ordinary residence of Réné, duke of Anjou and Lorraine, who died here, A.D. 1480. Upon the death of Charles, count of Maine, successor of Réné, Marseille came directly under the government of the French crown, to which it has ever since remained subject.

In the war of the emperor Charles V. with François I. of France, the Constable Duke of Bourbon [BOURBON, CHARLES DE] at the head of an army of Imperialists besieged Marseille (A.D. 1524), but was bravely repelled by the townsmen. In the year 1536 the town was again unsuccessfully attacked by the Imperialists under Charles V. in person and the Duke of Alba. In the religious troubles of the sixteenth century a plot was formed (A.D. 1585) to betray Marseille into the power of the League, but it failed. Subsequently however the partisans of the League gained a complete ascendancy in the city, which became the prey of intestine commotions, until the Duke of Guise, governor of Provence, for Henri IV., was admitted (A.D. 1596) by the partisans of that monarch. In the reign of Louis XIV. the municipal privileges of the city were diminished, and forts were built, as much probably to control the townsmen as to defend the place. In A.D. 1720, 40,000 or 50,000 of the inhabitants were swept away by pestilence. Belzunce, bishop of Marseille, the echevins or municipal officers of the town, and three physicians of Montpellier, distinguished themselves by their courageous performance of their duties at this trying season. In the Revolution the Marseillois acted a conspicuous part. A band of political fanatics went to Paris, and were among the leaders in the attack on the Tuileries, in August, 1792. The townsmen attempted, but in vain, to support by an insurrection the Girondists against the party of the Mountain.

The city of Marseille is built on the coast of the Mediterranean, which here runs north and south. The harbour is formed by a small inlet of the sea, running eastward into the very heart of the city, which is built round it. Its immediate site is a rich valley or hollow enclosed on the land side by hills, of which the highest is that of Notre Dame de la Garde, on the south, surmounted by a fort. From the summit of the hill of Viste, on the north side of the town, over which the road from Paris leads, three miles distant, a fine view is obtained of the town and of the numerous country-houses (said to be five or six thousand in number) which occupy the surrounding part of the valley. The town was once fortified, and there are some remains of its walls and bastions. The entrance from Paris is by a fine broad planted road or wide street, which extends into the heart of the town, and is prolonged in a direct line, by a street of less width, quite through the town. To the west of this street is the old town, occupying a triangular point north of the harbour. The other parts constitute the new town, which consists of broad straight streets, provided with paved foot-paths and lined with well-built houses. The port, an oval of more than half a mile long and about a quarter of a mile broad, and capable of containing 1200 vessels, is surrounded by fine quays used as a promenade by the townsmen in the winter. There are several other promenades, the finest of which is that of Tourette, or the Esplanade, on the shore in the old town. The places or squares are more numerous in the old town than in the new, but neither so large, so regular, nor so ornamental. The town-hall built by the architect Puget, faces the harbour; the ground-floor is used as the Exchange; the great council-chamber has some fine paintings. There are a new market-house supported by thirty-two columns of the Tuscan order, a fish-market, and other markets; a lazaretto on the shore, north of the city, one of the finest and best managed in the world. There are also a mint; two theatres, the chief of them one of the finest in France; a triumphal arch, a column, and several public fountains. Water is brought from the little rivers Huveaune and Jarret by an aqueduct almost entirely subterranean; and many houses have wells, the water of which is drinkable.

The population of Marseille in 1789 was 76,222; in 1801, 111,130; in 1811, 102,217; in 1821, 109,483; in 1831, 121,272 for the town, or 145,115 for the whole commune; and in 1836, 146,239 for the commune. It is the third city in France for population, being exceeded only by Paris and Lyon. The city has always depended for its prosperity on commerce. The harbour is very safe. Opposite the mouth of it, which is narrow, not permitting the entry of more than one ship at a time, are the three small islands of If (having a castle once used as a state prison, and numerous batteries), Ratonneau, and Pomègue, which are both fortified. The entrance to the port is defended by two forts; that of St. Jean on the north, and that of St. Nicholas on the south. Fort St. Nicholas, which was converted by Louis XIV. into a citadel, has been in great part demolished by the townsmen.

The port is not deep, and is liable to be filled by the mud brought down by the rain from the neighbouring hills: machines are continually at work to keep it clear. Frigates cannot enter without difficulty; ships of the line cannot enter at all, but are obliged to anchor in the road between the islands of Ratonneau and Pomègue, where also vessels perform quarantine. This anchorage is secure. The number of vessels which enter the port is estimated at 5000 or 6000 in the year; and the customs and other dues collected are estimated at nearly 1,000,000*l.* annually. The French trade with the Levant is entirely carried on from this port; and there is active communication with Italy, Spain, and Barbary. The imports are of raw cotton, sugar, dye-woods, and of divers articles from the Levant. The exports are of wines, brandy, corn, dried fruits, oil, soap, hosiery, damask and other linens, woollens, silks, leather, hides, and colonial produce. The chief manufactures are those of soap, morocco and other leather, glass, porcelain, hats, caps, starch, gunpowder, snuff, alum, sulphur, vitriol, nitre and other chemicals, glue, wax-candles, straw-hats, and cutlery. The refining of sugar and salt, calico-printing, the distillation of brandy, essences, and liqueurs, cork-cutting, and the preparation of anchovies and other salt provisions, dried fruits, olives and wine for exportation, are carried on. The city is from its commercial character the resort of foreigners of all nations; and the variety of costume, continual bustle, and medley of languages which this occasions are among the most striking features of the place. The character of the people is by no means favourably drawn by our authorities.

Marseille has communications by daily public conveyances with Lyon, Aix, Avignon, Nîmes, Toulon, Grenoble, and other places; and by steam-boats at brief intervals with Nice, Genoa, Leghorn, Bastia, Civita Vecchia, and Naples; and at longer intervals with Port Vendre, Barcelona, and Valencia. It abounds with hotels and has some public baths and handsome cafés. The mistral, a keen, parching, and often tempestuous wind, blights all verdure, and its blasts are interchanged with the scorching rays of an unclouded sun; swarms of gnats infest every corner night and day, and the scorpion is often found in the houses and occasionally even in the beds.

Marseille has a custom-house, a stamp-office, an exchange, and a board of trade; a commercial court, a subordinate justice court, and a tribunal for the regulation of the fisheries and the settlement of disputes respecting them, the members of which, called Prud'hommes, are annually chosen by the fishermen from among themselves; and several other government or other public offices. There is also an arsenal.

The parish and other Catholic churches and chapels are twenty in number; there are a Protestant church and a Jews' synagogue, with several hospitals and other charitable institutions. There are, an academy of sciences, belles-lettres, and art; an agricultural and a medical society; a high-school, schools of medicine, drawing, music, and navigation; a deaf and dumb school; a public library of 60,000 volumes, a picture gallery, a museum, two botanic gardens, and an observatory. Literature is not much cultivated at present: astronomy and navigation are the studies chiefly pursued. Marseille has produced several learned and eminent men. The navigator Pytheas and the poet Petronius Arbiter, in ancient times, and the architect Puget, in modern times, are the chief.

Few antiquities have been discovered at Marseille, and there are no remains of ancient buildings; some statues, urns, and medals have been dug up.

The diocese of Marseille comprehends the town and its arrondissement. The bishop is a suffragan of the archbishop of Aix. The town is the head-quarters of the 8th military division, which includes the departments of Basses Alpes, Vaucluse, and Bouches du Rhône. The arrondissement comprehends an area of 252 square miles, and comprehends nine cantons, or districts, each under a justice of the peace, and sixteen communes. The population was 178,565 in 1831, and 180,127 in 1836.

Coin of Marseille.

British Museum. Actual size. Silver.

MARSHAL, a term which, in its origin, meant simply a groom or manager of horses; but from the importance of such an employment in a rude warlike nation, the office of marshal became invested with great military authority, which, according to the usage of the times, drew to itself a considerable civil jurisdiction. One of the principal officers of state is the king's marshal, which office is now held hereditarily by the duke of Norfolk, who is said to have the office of marshal of England, and also an honour in respect of which he is earl marshal. This office was executed in time of war in the king's host or army; in time of peace, in the aula regia, or king's great court. Upon the division of the aula regia the marshal appointed deputies in the new courts. In the King's Bench, the marshal's deputy was called the marshal of the marshalsea of the king's court, or marshal of the King's Bench. In the Exchequer, the deputy was marshal of the Exchequer, or clerk of the marshalsea of the Exchequer. The duty of the acting marshal is regularly to attend the court, and to take into his custody all persons committed to his custody by the court.

The lord high constable, when there was one, and the earl marshal, were the judges before whom the court of chivalry or court martial was held. This court had cognisance of contracts touching deeds of arms and of war arising out of the realm, and of all appeals [APPEAL] of offences committed out of the realm, and of matters within the realm relating to war, in cases which the courts of common law were incompetent to decide. Its proceedings were according to the course of the Roman or civil law. The earl marshal cannot hold this court alone, and there has been no hereditary or permanent high constable since the forfeiture of the duke of Buckingham, 'poor Edward Bohun,' in the time of Henry VIII. In the few cases in which the court of chivalry has been since held, a high constable has been appointed for the occasion. In the case of an appeal of death brought in 1583 against Sir Francis Drake by the heir of one Dowtie whose head Drake had struck off in parts beyond sea, Queen Elizabeth refused to appoint a high constable; and thus, says Lord Coke, the appeal slept. The minor duties of the earl marshal are set out with great minuteness of details in a document preserved in Spelman's 'Glossary.'

Besides the earl marshal, there is a knight marshal, or marshal of the king's household. The office of earl marshal, and that of marshal of the King's Bench, as well as that of the knight marshal, is called a marshalsea; but the term is ordinarily applied to the last only.

MARSHALSEA. In the Marshalsea of the king's household there are two courts of record. 1. The original court of the marshalsea is a court of record, to hear and determine causes between the servants of the king's household and others within the verge, that is, within a circle of twelve miles round the king's palace, with a jurisdiction of pleas of trespass where either party is one of the king's servants. 2. The palace court was erected by letters patent, 6 Charles I., confirmed by Charles II., and has authority to try all personal actions between party and party, though neither of them be of the king's household, provided they arise within twelve miles round Whitehall. The judges of this court are, the steward of the king's household and knight-marshal; but the court is, in fact, held before a barrister deputed by the knight-marshal. The palace court is held once a week in Scotland Yard, and causes are here brought to trial in four or five court-days, unless they are of sufficient magnitude or importance to induce either party to remove it into one of the superior courts. A writ of error lies from both courts into the court of king's bench.

MARSHAM, SIR JOHN, born 1602, died 1685. The noble family of Marsham have the honour of tracing themselves to a man whose chief distinction it was, that he was one of the most eminent scholars of his age, as the founder of their hereditary honours. He was one of six sons and four daughters of an alderman of London, and was born in the parish of St. Bartholomew. He had his education in Westminster school, and St. John's College, Oxford. He afterwards travelled much abroad in France, Italy, and Germany, both as a private gentleman and in the suite of Sir Thomas Edmunds the ambassador. When he returned home he betook himself to the study of the law, but it does not appear that he attained to more than to be appointed one of the six clerks in Chancery, and even this office he lost when the contentions arose between the king and the parliament. Nor was this all; for, following the king to Oxford, and remaining attached to the royal cause, he suffered greatly in his estate. On the change of the times he was returned to parliament for the city of Rochester, was restored to his six clerks' office, was knighted, and soon after was created a baronet. He died at Bushy Hall near Watford.

Such is the outline of his life. The predominance of a political power to whom he was obnoxious, in the period of his life when his mind was at maturity, gave him leisure to pursue those studies for which he had acquired a taste in the earlier period of his life. The subject on which his mind was particularly directed is one of peculiar intricacy and difficulty, the disentangling the perplexed statements to be found in early writers concerning antient dynasties and events in the earliest periods of history. The results of these studies he gave to the world in a folio volume, printed at London in 1672, which he entitled 'Canon Chronicus, Ægyptiacus, Ebraicus, Græcus,' being an enlargement of a work on the same subject published in 1649, entitled by him 'Diatribe Chronologica.' Sir John Marsham has treated the subject in a manner befitting a scholar intent on nothing but the discovery of truth, if truth be attainable. His work published at Leipzig in 1676, and at Franeker in 1696, a preface by the editor Menckenins, in which some of conclusions are questioned. It is probable that the ern discoveries in Egypt may affect in some points the ment of this learned scholar.

In the same spirit he attacked the difficulties which rest on the 'Chronology of the Early History of Persia:' but this work has not, we believe, been given to the public; nor the 'Dissertations on the Money of the Antients,' and on the 'Roman Provinces and Legions,' which it is understood he left in manuscript.

There is another work of his, less celebrated, the Preface, or Προπυλαιον, as he called it, to the great work on English monasteries, entitled 'Monasticon Anglicanum,' which was begun by Roger Dodsworth, and finished by Sir William Dugdale. This appeared in 1655.

Sir John Marsham was not only himself learned, but his two sons, Sir John Marsham of Cuxton, and Sir Robert Marsham of Bushy, were also studious and learned men. The son of Sir Robert was created Lord Romney by King George I.

MARSHES are those places of greater or less extent on the earth's surface, where the soil is almost constantly soaked with water. The swamp, the bog, the fen, and the morass, are so many different names for the same thing, or modifications which have not yet been defined. Whether marshes be considered with regard to their advantages or disadvantages, they are equally interesting, and are objects that call for the attention of individuals and sometimes of states. The advantages which they offer are of limited extent, and may be divided into spontaneous and artificial. The former consist in the natural productions which are furnished by some of them, of which peat is unquestionably the most important. (Ireland, Holland.) Some furnish iron-ore in considerable quantity, and, though generally of a bad kind, it is sometimes very good, and worked with advantage (Siberia); others supply aquatic game in abundance, which is a great resource to the neighbouring inhabitants, either for consumption or as an article of commerce (the marshes of Tuscany); others again abound in eels and other fish; and some, as those of the Saône in France, and those of Poland, are valuable for the myriads of leeches which they furnish, and which are sent to distant parts. The soil itself, dug up from the marshes, which is called bog-earth, and the upper surface of the peat bogs, burnt or unburnt, are in many cases considered an excellent manure, and employed as such. (Poland, France.) The reeds, rushes, willows, &c., which grow so abundantly in certain marshy lands, are in many places objects of considerable importance. (Italy, Holland.) The artificial advantages to which marshes may be turned are confined chiefly to the cultivation of rice, where climate and other circumstances are favourable to the growth of this grain. (North America, Hungary.) The disadvantages of marshes are great: they are in general fatal to health, and agriculture suffers by the loss of all the marshy land. That health is materially injured by the pestilential air of marshes is evident from the fact that the ordinary mean length of life in their neighbourhood is very low. Cattle are also great sufferers from the influence of marshy grounds. The engineer Rauch says, 'Marshes are the ulcers of the earth, which blur the fair face of nature, where all should be beauty; and from these infectious sores the languor of death extends far and wide over all that should live and flourish:' but the details of their baleful influence are nowhere more strikingly set forth than in the prize essay on this subject, by M. Ramel of Paris. Nevertheless all marshes are not equally prejudicial to health; but independent of their different degrees of insalubrity, marshes present other distinguishing features. The climate, the nature of the soil, and the vegetation, are all so many circumstances which vary the appearance and character of marshes. The quantity of water is also very different; in some cases it is hardly visible, while in others, at least in certain seasons, the marsh presents the aspect of a multitude of stagnant pools covered with aquatic birds. This is the case with many of the Tuscan marshes, which are moreover remarkable for their floating islands, which sometimes unite and cover a large surface: these islands have little solidity, and, eventually sinking, become in time converted into peat: some of these marshes gain in extent, while the soil of others gradually rises, and the marsh disappears. Reeds are particularly abundant in the Tuscan marshes, and they are applied to a great number of useful purposes. The quality of the marsh-water also differs: thus, in some of the marshes of South Carolina, in the United States, it is salt, as likewise at Rochelle, Rochfort, &c., in France. In other places it is sui-

[illegible], as is the case with the marshes of Mesopotamia; in many it is ferruginous, as in Siberia, where the marshes are strongly impregnated with sulphate of iron from the vitriolic springs which flow into them. The trees which are found imbedded in these marshes are so thoroughly impregnated with oxide of iron, that they supply an ore of excellent quality, furnishing a metal free from the defect of brittleness so common to the iron of most other bog ores. In some cases the water of the marsh exhales an intolerable smell of sulphuretted hydrogen, arising from the decomposition of the sulphate of magnesia or Epsom salt, which is continually forming on their banks. (*Siberia*, and the banks of the Euphrates.)

In cold countries marshes freeze, but seldom become dry; in warm countries, on the contrary, the marshes are often dry, and such can never form peat. As to the vegetation of marshes, it is either composed of reeds, rushes, algæ, gramineæ, or mosses, of which the *sphagnum palustre* is the most common in peat bogs. Brushwood of various kinds, and willows and alders, are also common in marshy grounds.

Marshes are found in all kinds of situations, in continents and in islands (Ireland, Arran, &c.), on the margin of the sea, as well as in the interior of the land, on the slopes and even on the summits of mountains, as well as in the plains. Most countries have them in greater or less abundance, but it has been remarked that they are less common in Asia and in Africa (as far as the latter is known) than in Europe, and that they are more abundant in America than elsewhere. In this latter part of the world almost all the plains are wet and abound in marshes; they are exceedingly common in the northern countries of the globe, particularly in the flat parts bordering on the sea, where the land is low and the subsoil clay. Here the rain and snow-water accumulate, and remain for want of sufficient evaporation to carry them off.

It would be impossible to enumerate all the existing marshes: we may however observe that in Italy there are the Tuscan and the celebrated Pontine marshes, which are of great extent; in France there are about 1,550,000 arpens, or French acres, of marshes, some of great celebrity, as that of Montoire near the mouth of the Loire, which has been worked for its peat for upwards of five hundred years, and gives constant employment to 4000 persons. Ireland contains about 3,000,000 acres of marsh; the marsh or bog of Allen alone contains 300,000 acres, and there are others very extensive. England has many marshes, particularly in Lincolnshire, Somersetshire, Kent, and Cambridgeshire; Cheshire, Huntingdonshire, Lancashire, and Stafford have extensive marshes, some of which contain embedded trees. Scotland is much diversified with marshy ground, as in Perthshire, Ayrshire, Stirlingshire, Kinross, &c. As for Holland, the whole country is properly a drained marsh, and it still contains some extensive bogs which furnish peat. All the space along the coast from Holland to Denmark is little better than a succession of marsh and sand. Russia in Europe has marshes of vast extent, as those at the source of the Don, along the river Pripetz, and round the sea of Azoff, as also in Finland and the Baltic Provinces, in Lithuania and Poland. The eastern part of Prussia abounds in swamps. Norway and Sweden have some bogs, but little in proportion to their territory. In Bessarabia in Turkey, and all along the lower Danube, there are extensive marshes covered with reeds. In Hungary the marshes are estimated at 2,000,000 arpens. Switzerland has some considerable swampy patches, many of which are on the slopes of the mountains and in the higher valleys. In Spain and Portugal there are some extensive marshes; indeed they are more or less scattered all over Europe.

Asia has its marshes and swamps, but they are less common than in Europe, if we except the northern portion, where they are in great number and very extensive, as between the lower Ob and the Yenisei, and between this last river and the Lena. There is between the little Tunguska and the Yenisei the marsh called Lis, equal in extent to the great lake Ladoga, enveloped as it were in the midst of woody hills. The province of Okhotsk has many swampy forests. A large part of China is naturally swampy, but it is to a great extent drained by the numerous canals which intersect the country. Tonquin has many marshes, and the peninsula of Malacca contains many of great extent. In India the province of Oude has some extensive marshes covered with reeds, the retreat of great herds of wild buffaloes. The mouths of the greater part of the rivers of India are marshy, and large swamps are sometimes found along their course, as is the case with the [illegible]. In the northern provinces there are many savannahs, or wet meadows. There are swamps along the Euphrates, and those of Mesopotamia are bitter, sulphureous, and salt. In Persia the province of Ghilan, in other respects fertile and beautiful, is very unwholesome on account of its marshes and marshy forests. Mazanderan has also many swamps. The eastern side of the lake Aral is marshy. The steppes of the Kirghiz abound in salt marshes and pools. The Asiatic islands, that is all those that are of any extent, contain marshes: that part of the coast of Sumatra is covered with extensive marshes, which have caused it to receive the name of 'the pestilential coast;' the reeds are gigantic bamboos, and a continual fog hangs over the aquatic soil. Batavia, Samarang, and other places in the island of Java are reputed to be so unwholesome, in consequence of the stagnant waters and pestilential marshes, that the island has been named the grave of Europeans. The Philippine Islands have a great many peat bogs. New Holland has much marshy ground along the coast, and immense swamps have been seen inland.

As for Africa, its interior is too little known to enable us to speak with any certainty of its marshes; but the southern part, according to Barrow, has many and extensive swamps covered with reeds and saline plants. Some of the rivers on the east are marshy at their embouchures, which is also the case with the Quorra. Madagascar contains marshes, in which the singular Ravenala (*urania speciosa*), a kind of palm, grows, remarkable for the size and disposition of its leaves, which are similar to those of the banana, and are employed by the natives as table-cloths, napkins, plates, dishes, and spoons.

America contains immense marshes. In the frigid zone of the New World, as far as known, fog-enveloped marshes have been found. To the westward, in Russian America, the land lying between the coast and the mountains is a slip of black swampy soil; some of the marshy grounds are on the slopes of the mountains, and retain the water like a sponge; their verdure (being covered with moss of various kinds) gives them the appearance of firm land, but in endeavouring to pass them the traveller sinks up to the waist. On the opposite or east coast of America we find Newfoundland intersected by marshes and morasses. Lower Canada has neither marshes nor stagnant water, but the rivers are muddy. To the south of the great lakes of North America, and as far south as Mexico, the United States contain a great number of marshes, and some of them of great extent. The low lands of Mexico also contain many swamps. The former intendancy of Vera Cruz is principally occupied with marshes and pools. South America contains a great abundance of extensive marshes, as on the upper Apure, an affluent of the Orinoco, and the delta of the latter river is one vast swamp. The region which extends between the Andes and the Pacific has little marshy ground, if we except Choco, where there are many swampy valleys; but on the other hand the immense plains which occupy the whole interior of the continent, from the mountains of Caracas on the north to the Straits of Magalhaens on the south, contain a great number of extensive marshes. All the immense basin of the Amazon is covered with swamps and wet land and marshy forests. To the south of the Campos Parexis, the provinces of Moxos and Chiquitos contain extensive marshes; in the latter particularly there is the great lake or marsh of Xarayes. (Brazil, p. 356.) This marsh is temporary however, being dry a great part of the year, and then covered with the corn flag (*gladiolus*) and other *iridiæ*. The province of [illegible] is also full of marshes, as well as that of Cordova, in which are the swamp of Las Porongos, the Mar-chiquita, &c. In La Plata there is the great marsh of Ybera, formed by the infiltrations of the Parana. At the north-west extremity of the Pampa of Buenos Ayres is the great sandy marsh called Las Canaverales, and along the whole course of the Rio Mendoza, and between that river and the foot of the Cordilleras there are extensive marshes. They also exist on the upper part of Rio Negro. In short, we may say that all the immense region of the Pampas, or plains of South America, contains marshes. Brazil has many swampy woods; and in ascending the coast we find the great island of Marajo at the embouchure of the Amazons, a considerable tract of which is a marsh formed in part by the deposit from the water of the river, and in part by the sands of the sea. Farther north again the whole coast of French Guyana is a swamp.

This enumeration of the known marshes and swamps, though comprehensive, is however far from being complete. Very large portions of the earth's surface remain still unexplored, and physical geography is yet too modern a science to have attracted the attention of travellers to the correction and completion of its details. Nevertheless it is certain that the extent of marshy ground is very great; and probably it was formerly much greater, for a multitude of natural circumstances have greatly diminished them, and are still effacing them by degrees. On the other hand colonization, and the consequent increase of population in the newly settled places, cause the clearing of forests and the draining of marshes to go on rapidly. There is no doubt but that in proportion as the swamps are dried up the source of many diseases will be got rid of; but again, it may be doubtful whether the increased drought occasioned by so vast a reduction of evaporating surface may not engender other diseases equally fatal with those which now spring from the superabundance of swampy ground; and it is possible that even absolute sterility may result, in some cases, from imprudent drainage.

MARSIAN WAR. [SOCIAL WAR.]

MARSIGLI, LUIGI FERDINANDO, COUNT, born at Bologna, of a noble family, in 1658, studied mathematics under Borelli, and natural history under Malpighi and other able professors. At the age of twenty he went to Constantinople. On his return he published 'Osservazioni sul Bosforo Tracio' (Rome, 1681), which he dedicated to Christina of Sweden; and he also wrote a memoir on the rise and decline of the Ottoman empire, which was not published until after his death. He afterwards served in Hungary as a volunteer in the Imperial army against the Turks, was raised to the rank of captain, and was wounded and taken prisoner at the battle of Raab, in 1683. He was sold as a slave, and, after suffering considerable hardships, was ransomed by his family. He was then employed by the emperor Leopold I. as an engineer, to settle the boundary-line of the Austrian dominions on the side of Turkey, agreeably to the treaty of peace between the two empires. When the war of the Spanish succession broke out, Marsigli, who was already a general, was actively employed, and he found himself in command of the garrison of Brisach, of which town the Count d'Arco was political governor. Brisach surrendered to the French thirteen days after they had opened the trenches. The aulic council of Vienna highly disapproved of the surrender, and Marsigli was publicly sentenced to be cashiered. He tried every means to have the sentence revoked, but in vain. He wrote and published a memoir in his defence, which is said to have appeared perfectly satisfactory to competent judges, and among others to Marshal Vauban. From that time he devoted himself to study; he travelled in France, was numbered among the members of the Academy of Sciences of Paris, and at last returned to his native town Bologna, to which in 1712 he made a donation of his scientific collections, which were placed by the senate of Bologna in a building allotted for the purpose, and called the Institute of Sciences and Arts. In 1726 Marsigli published his great work on the Danube, 'Danubius Pannonico-Mysicus, Observationibus Geographicis, Astronomicis, Hydrographicis, Historicis, Physicis, perlustratus ab Aloysio Ferdinando Comite Marsili, socio R. Societatum Parisiensis, Londinensis,' etc. (Amsterdam, 7 vols. folio, with handsome plates). The first volume treats of the geography of Hungary, Servia, and other countries bordering on the central Danube; the second, of the antient monuments in the same; the third, of the geology; the fourth, fifth, and sixth, of the ichthyology, zoology, and ornithology; and the last contains a catalogue of the plants, and treats of the nature and properties of the waters of the Danube and its great affluent the Theiss.

MARSTON, JOHN, a dramatist in the reigns of Elizabeth and James I., the particulars of whose life, and even the exact times of whose birth and death, are, like those of many of his contemporary poets, very uncertain. On the testimony of Wood, he seems to have been a student at rpus Christi College, Oxford. At one time he appears have been intimate with Ben Jonson, if we may judge n his dedication to that poet of the 'Malecontent;' but n the epistle to the reader prefixed to his 'Sophonisba,' it seems that his friendship subsequently ceased, as that epistle contains severe strictures on Jonson for his use of passages from classical authors in his tragedies of 'Sejanus' and 'Catiline.'

Marston left several plays, of which the following have been printed separately:—'Antonio and Mellido,' 'Antonio's Revenge,' 'Dutch Courtezan,' 'Insatiate Countess,' 'Malecontent,' 'Parasitaster,' 'Sophonisba,' 'Tamerlane the Great,' and 'What you will.' Of these the 'Malecontent,' an excellent play, abounding in causticity, and embellished with the most forcible poetic expressions, is printed in Dodsley's Collection. It appears however from the title-page of the first edition (1604) that this piece was written by Webster, and only altered by Marston. He also left some miscellaneous poetical works, collected and edited by Mr. Bowle in 1764; and he assisted Ben Jonson and Chapman in the composition of 'Eastward Hoe,' a play which is in Dodsley's Collection.

MARSTRAND. [SWEDEN.]

MARSUPIA'LIA, or MARSUPIA'TA (*Marsupium*, a purse or bag), an extensive group of Mammalia, differing essentially from all the others in their organization, and comprehending genera fed by every variety of nourishment. Their structure is, as a necessary consequence, modified accordingly; and we find among them an adaptation of the organs of progression, prehension, and digestion to their several wants and habits, so that we may trace in them analogies to the carnivorous, insectivorous, herbivorous, and rodent forms of the other mammiferous quadrupeds.

The first species belonging to this anormal or aberrant group brought under the notice of zoologists were those of America, and they received from Scaliger the appropriate name of *Animalia crumenata*, or *Purse-bearing animals*; for the leading peculiarity in these Marsupials is, so to speak, the premature birth of their young, which are born in a state of development not much beyond that of the fœtus in the other groups, at a very early stage of pregnancy, and attach themselves by the mouth to the teats, which are situated in the marsupium, or pouch, of the mother; and in this nidus, or, as it may be termed, second uterus, the almost embryotic young one is nourished till the little knobs that marked the place of the extremities shoot out into limbs, and till the whole frame-work of the animal is completed, and it is able to go alone. Long after this period it flies to the pouch upon the approach of danger, or enters it when fatigued, and may often be seen peeping out to ascertain whether it is safe to venture abroad again.

Linnæus, who appears only to have known the American species, or Opossums, arranges them under the generic appellation of *Didelphis*,* in his order *Feræ*, placing them between the Bears, Badgers, and Racoons, &c. (*Ursus*), and the Moles (*Talpa*).

Cuvier, who had the advantage of knowing the great quantity of species and variety of forms discovered in New Holland, arranged the copious materials which that extraordinary country afforded in addition to the few American forms, as the fourth order of his *Mammifères*, dividing the numerous group into several subdivisions, and placing the order between his *Carnassiers* and his *Rodentia*.

Illiger makes the *Marsupialia* the sixth family of his second order, *Pollicata*; and his third order, *Salientia*, consists of the Kangaroos and Potoroos.

M. de Blainville divides the *Mammifères* into two subclasses; the first being the *Monadelphes*, and the second the *Didelphes*, which last consists of the *Marsupiata* and *Monotremes*, properly so called: we say properly so called, because, strictly speaking, every Marsupial female is a *Monotreme*.

Mr. Gray collects all the forms under the family *Didelphidæ*. The subfamilies into which the group is separated by him will be found in the article MAMMALOGY, where the views of zoologists in general, as to the classification of the animals, will be found.

Storr congregates all mammalia with opposable thumbs into one great group, which he divides into three sections: the first consisting of the genus *Homo*; the second of the genera *Sima*, *Prosimia*, *Procebus*, *Tarsius*, and *Lemur*; and the third of the genera *Didelphis* and *Phalanger*.

Mr. Ogilby separates his *Cheiropeds* (Mammals with opposable thumbs) into the three groups, *Bimana*, *Quadrumana*, and *Pedimana*, which last are characterised as having

---

* Or more properly 'Didelphys,' signifying 'double uterus.'

ing opposable thumbs on the hind hands only. The [illegible] [illegible] of the families [illegible] (with [illegible] teeth) and the [illegible] (with [illegible] teeth). These last consist of the genera [illegible], Phalangista, Petaurus, [illegible], [illegible], [illegible] and [illegible]. ('Nat. Hist. of Monkeys, Opossums, and Lemurs,' Menageries, vol. ii., 1838.)

Before we proceed to notice the classification proposed by Professor Owen, it will be advisable to draw the attention of our readers to the Marsupial

ORGANIZATION.

Skeleton.—The Marsupials differ considerably from each other in the osseous part of their structure, as might be expected in a group whose food and habits vary so much. Our limits do not permit of a detailed inquiry into these differences; but the examples given in the skeletons, skulls, and teeth represented in this article will convey a general notion of the formation of the bony parts, and the modifications to which they are subject. There is however one peculiarity common to all, which is even found in the true *Monotremes*, and presents a marked discrepancy from the osseous systems of the other Mammalia;—we allude to the *Marsupial Bones*. These are attached to the pubis and imbedded in the muscles of the abdomen, where they afford support to the marsupium, or pouch, in the females. They exist also in the males, to whom their presence seems to be necessary for the purposes of reproduction. These bones and their situation are shown in the skeletons of the Kangaroo and Opossum. The principal modifications in the general form of the skull and in the other parts of the skeleton are well pointed out by Professor Owen in his paper 'On the Osteology of the Marsupialia.' (*Zool. Proc.*, Oct., 1838.)

Organs of Digestion.—These, as might also be expected, vary greatly. The teeth are appropriated to the food or prey to be taken, whether it be flesh, insects, fruits, herbs, or roots; and in conformity with the same law, we have a simple or a complex stomach, and a corresponding structure in the viscera; the flesh-eating tribes being entirely without a cæcum, and the others possessing that appendage in a greater or less degree according to circumstances.

Organs of Reproduction.—But it is in the organs of generation and mode of reproduction that the great and striking difference exists between the Marsupials and all other known Mammals. 'Tyson first distinguished the true *vaginæ* from the *urethro-sexual canal*, as it has been termed by later physiologists, though he denominated it the *common passage* or *canalis*; nor was his conjecture as to the parts of the complicated uterine apparatus wherein gestation is carried on other than true. John Hunter, Sir Everard Home, M. Geoffroy St. Hilaire, M. de Blainville, and Mr. Morgan have all thrown more or less light upon this obscure subject; and the paper of Mr. Morgan, in the 'Transactions of the Linnean Society,' vol. xvi., is especially worthy of attention, so far as it goes. But it was reserved for Professor Owen to supply the many and great deficiencies which existed, and to obtain a precise knowledge of the mode in which the embryo is developed, by determining from the examination of the impregnated uterus the nature of the relations subsisting between the fœtus and the mother.

Professor Owen, in his paper 'On the Generation of the Marsupial Animals, with a Description of the Impregnated Uterus of the Kangaroo' (*Phil. Trans.*, 1834), observes that in all the genera of this group the uterus is double and the true vagina is separated either wholly or for a considerable extent into two lateral canals. Both the digestive and generative tubes terminate within a common cloacal outlet, and the term *Monotremata* therefore, he remarks, though confined to the edentate *Monotremata*, is so far applicable to the whole of this aberrant division. As the females approach the Oviparous *Vertebrata* in their separate genital tubes, so also the males resemble them in the peculiar structure and connexions of the intromittent organ; and he points out that in the *Wombat*, the *Dasyure*, and the *Phalangista* the corpora cavernosa penis have the same position below the pubis, with the same want of ligamentous attachment to the bony pelvis; and the glans has the same bifurcated form and double groove for the transmission of the semen as in the Opossum, in which these peculiarities in the male organs were first described by Cowper (*Phil. Trans.*, 1704). 'In most species,' continues Mr. Owen, 'in which the females have an inward fold of integument, or abdominal pouch, the males have an outward duplicature in the corresponding situation for the lodgment of the testes, which are thus placed anterior to the penis; and it is a remarkable fact that the muscle which compresses the mammary gland in the one sex is analogous to the suspensory cremaster of the testes in the other. Both sexes in the Marsupial genera manifest also their affinity to the oviparous classes in possessing two superior venæ cavæ, and in the want of the inferior mesenteric artery; and the marsupial bones, so common in the skeletons of reptiles, are limited in the mammiferous class to this division, in which alone, from the peculiarly brief period of uterine gestation, and the consequent non-enlargement of the abdomen, their presence might be expected. But these bones serve important purposes in relation to the generative economy of the *Marsupiata*. In the female they assist in producing a compression of the mammary gland necessary for the alimentation of a peculiarly feeble offspring, and they defend the abdominal viscera from the pressure of the young as these increase in size during their mammary or marsupial existence, and still more when they return to the pouch for temporary shelter. In the males, with the exception of the edentate genera, the marsupial bones, from their relation to the cremaster muscles, which wind round them like pulleys, assist in the compression and retraction of the testes during *coitus*; a process which, from the peculiar position of the scrotum, has been supposed to differ from that of other quadrupeds. A recent opportunity however of observing the coitus of the Kangaroo, at the Zoological Gardens, proves that there is no difference as to position, which is the same as in the Dog, but that it is chiefly remarkable for the repetition of the act during a long-continued embrace. The peculiar length and tortuosity of the double vagina, for which the bifurcated glans of the male organ is adapted, may render necessary so efficient a process; and as the testes are then retracted entirely out of sight, it would seem that the marsupial bones have the same relation in the male to their scrotum as they have in the female to the mammary glands. The minute size of the young of the American Opossum when found in the marsupium, their pendulous attachment to the nipples, and perhaps the mode in which the latter are developed, gave rise among the earlier observers to a supposition that they were originally formed from those parts; and the gemmiparous theory, which has subsequently often been revived, appears to have been prevalent at the time when Tyson first devoted his attention to the subject.'

Professor Owen, after concluding, from data stated in his paper, that it may be concluded that the ovulum in the Kangaroo quits the ovary in a condition corresponding to that in the ordinary *Mammalia*, and increases in a similar manner as it descends to the uterus, goes on to describe in minute and most interesting detail the fœtus and membranes of a Kangaroo (*Macropus major*) at apparently the middle period of gestation, which in that animal continues for thirty-eight days. The membranes consisted of an amnion, a very large vitelline sac, rendered highly vascular by ramifications of omphalo-mesenteric vessels, and a thin unvascular chorion. There was no placenta, nor any adhesion between the external membrane of the fœtus and the internal surface of the mother by the opposition and interlacement of villi, or vessels, as in those *Mammalia* in which the placenta is replaced by a uniform villous and vascular chorion; the condition of the fœtus was such as occurs in the viper and other ovoviviparous reptiles, except that there was no trace of the existence of an allantois in that stage of the fœtal development. The dissection of very young mammary fœtuses of the Kangaroo, Phalangista, and Petaurus exhibited the remains of a urachus and umbilical vessels, whence Professor Owen concluded that at a more advanced stage of the fœtus an allantois was developed. Mr. Owen remarked that as the growth of the ovum advanced, the circulating fluids became necessarily more charged with decomposed particles of the organized substance; and that although the extended surface of minutely subdivided blood-vessels afforded by the vitelline sac might serve both for respiration and nutrition at the earliest stages, yet that at a later period, and as the embryo acquired additional bulk and strength and parts, an accessory apparatus for that end appeared to be necessary. In all the *Reptilia*, he observed, in which the respiratory function of the fœtus is not performed by the intervention of vascular filaments from the sides of the neck, an allantois or cæcal process, organised by umbilical or hypogastric vessels, is produced from the terminal portion of the intestinal tube. In the placental *Mammalia*, where the vitelline sac and vitellus are relatively smaller, the allantois makes its appearance much earlier, but is developed in different proportions in the different orders. It is subservient in all the placental *Mammalia* to the important function of the transference of the hypogastric or umbilical arteries to the exterior enveloping membrane or chorion; and in these *Mammalia*, Mr. Owen further remarked, the umbilical vessels coextended with the allantoic cæcum seek a more intimate contact with the vascular surface of the womb, and proceed to organise the chorion shooting out into villi, either extended over the whole surface, as in the mare, or disposed in circumscribed tufts, as in the *Ruminants*, or limited to one place and forming a single placenta, as in the human subject, and in all unguiculate mammals.

As connected with this subject Mr. Owen subsequently exhibited a preparation (of which a cut is given in Loudon's 'Magazine of Natural History,'* with the summary of the professor's paper in the *Phil. Trans.*) to the Zoological Society of London, and took occasion to observe that in the bird and reptile the umbilical vessels are limited to the allantois, and do not extend beyond that membrane to the chorion; the allantois therefore plays a primary part in the respiration of the fœtus. In the placental mammalia, on the other hand, its office as a temporary respiratory organ is secondary, but it is essential as a means of transference of the umbilical vessels to the chorion; it has therefore a pre-existence to the placenta, and without it the placenta could not be formed; for if it be considered that the embryo is formed within the bag of the chorion, and is originally free from any connexion with that membrane, there must of necessity be some support for the umbilical vessels during their passage to the chorion; but no other is known except the allantois, or urinary bladder, and urachus, as its remains are termed. The existence of a placenta, in Mr. Owen's mind, therefore infers the pre-existence of an allantois, but the reverse of the proposition does not therefore hold good. In birds and scaled reptiles the allantois itself performs the functions of the placenta or vascular chorion; and the question to be resolved relatively to the Kangaroo and other Marsupials was whether, the allantois being developed, it would serve as a medium for the organization of the chorion, or remain, as in the oviparous vertebrata, an independent vascular bag or cæcum. The examination of the preparation alluded to, a uterine fœtus of a Kangaroo placed at Mr. Owen's disposal by Dr. Sweatman, contributed to the solution of that question. This fœtus was further advanced than that described by Mr. Owen in *Phil. Trans.* The digits of the hinder extremities were, in this, completely formed. The umbilical chord extended nearly three lines from the abdominal surface of the fœtus; the amnios was reflected from this point to form the usual immediately investing tunic of the fœtus; and beyond the point of reflection, the chord divided into a very large superior vascular sac, organised by the omphalo-mesenteric vessels, corresponding in all respects with the vitelline sac described and figured in Mr. Owen's paper in *Phil. Trans.*; but below the neck of this sac there extended a second pyriform sac, about one-sixth the size of the vitelline sac, having numerous ramifications of the umbilical vessels, and constituting a true allantois. This sac was suspended freely from the end of the umbilical chord; it had no connexion at any part of its circumference with the chorion, and was equally free from attachment to the parietes of the uterus, in which the fœtus was developed.

The period of gestation (thirty-nine days) was determined in 1833, in the vivarium of the Zoological Society of London, by Mr. Owen, whose account of this hitherto obscure and most interesting portion of the natural history of the animal we here give from his paper in the *Phil. Trans.*

'In order to inure the female to the examinations of the pouch when they should become indispensable, they were commenced six days after the copulation, which took place on the 27th of August, and were repeated every morning and evening until the 5th of October, when, at 7 A.M., the fœtus was discovered in the pouch attached to the left superior nipple. On the preceding day at the same hour a great quantity of the moist brown secretion peculiar to the pouch was noticed, indicating a commencing determination of blood to that part, and at different periods during the day the female was observed to put her head into the pouch and lick off the secretion. When she was again examined, at six o'clock in the evening, a slight increase of the secretion was the only perceptible change in the state of the pouch: but there was no appearance in the nipples indicative of the event so soon about to take place. The nipple in use by the young one of the previous year was the right superior or anterior one; it was nearly two inches in length, and one-third of an inch in diameter, while the other three were about half an inch in length, and about a line in diameter. I took notes of the appearance of the marsupium on the 6th, the 10th, 15th, 21st, 30th, and 38th days of uterine gestation; no material alteration was however observable till after the death of the young Kangaroo of the previous year, which took place on the twenty-fifth day, when the brown secretion first began to appear, and the nipple that had been in use to diminish. As parturition took place in the night, the mode of transmission to the pouch was not observed. No blood or albuminous discharge could be detected on the litter, nor any trace of it on the fur between the vagina and orifice of the pouch; but these might have been removed by the mother. The appearances presented by the little one thus detected within twelve hours after being deposited in the pouch were as follow:—It resembled an earth-worm in the colour and semitransparency of its integument, adhered firmly to the point of the nipple, breathed strongly but slowly, and moved its fore-legs when disturbed. Its body was bent upon the abdomen, its short tail tucked in between the hind-legs, which were one-third shorter than the fore-legs, but with the three divisions of the toes now distinct. The whole length from the nose to the end of the tail, when stretched out, did not exceed one inch and two lines. On the 9th of October I again examined the pouch; the young one was evidently grown and respired vigorously. I determined to detach it from the nipple for the following reasons:—1st, to decide the nature of the connection between the fœtus and the nipple; 2nd, to ascertain, if possible the nature of the mammary secretion at this period; 3rd, to try whether so small a fœtus would manifest the powers of a voluntary agent in regaining the nipple; and lastly, to observe the actions of the mother to effect the same purpose, which one might presume would be instinctively analogous to those by means of which the fœtus was originally applied to the nipple. With respect to the first point, I was aware that the Hunterian dissections, as exhibited in the preparations in the museum of the college, and the observations of Mr. Morgan and Mr. Collie, concurred in disproving the theory of a vascular mode of connection between the mammary fœtus and the nipple; nevertheless as a discharge of blood had been stated by Geoffroy St. Hilaire to accompany marsupial birth, or the spontaneous detachment of the fœtus from the nipple, and even the anastomoses and distribution of the continuous vessels in the neck of the fœtus had been speculated on by him, it became desirable to have ocular demonstration of the facts.

The fœtus retained a firm hold of the nipple; when it was detached, a minute drop of whitish fluid, a serous milk, appeared on the point of the nipple. About half a line of the extremity of the nipple had entered the mouth, which extremity was of smaller diameter than the rest of the nipple, not being as yet so compressed by the contracted orifice of the mouth as to form a clavate extremity, such as it afterwards presents. The young one moved its extremities vigorously after being detached, but did not make any apparent effort to apply its legs to the integument of the mother, so as to creep along, but seemed, in regard to progressive motion, to be perfectly helpless. It was deposited at the bottom of the pouch, and the mother was liberated and carefully watched for an hour. She immediately showed symptoms of uneasiness, stooping down to lick the orifice of the vagina, and scratching the exterior of the pouch. At length she grasped the sides of the orifice of the pouch with her fore-paws, and drawing them apart, as in the act of opening a bag, she thrust her head into the cavity as far as the eyes, and could be seen moving it about in different directions. During this act she rested on the tripod formed by the tarsi and tail. She never meddled with the pouch while in the recumbent posture; but when stimulated by uneasy sensations, she immediately rose and repeated the process of drawing open the bag and inserting her muzzle, sometimes keeping it there for half a minute at a time. I never observed that she put her fore-legs into the pouch;

---

* Vol. i., New Series.

they were invariably employed to widen the orifice. When she withdrew her head, she generally concluded by licking the inside of the pouch and swallowing the secretions. After repeating the above act about a dozen times, she lay down, and seemed to be at ease.

[illegible]

'The freedom with which the mother moved with her mouth the orifices both of the genital passage and pouch suggested at once a means adequate to the removal of the young from the one to the other; while at the same time her employment of the fore-paws indicated that their assistance in the transmission of the foetus need not extend beyond the keeping open the entrance of the pouch while the foetus was being introduced by the mouth, when it is thus probably conducted to, and held over, a nipple, until the mother feels that it has grasped the sensitive extremity of the part from which it is to derive its sustenance. This mode of transmission is consistent with analogy, the mouth being always employed by the ordinary quadrupeds, as dogs, cats, and mice, for the purpose of removing their helpless offspring. It accords also with the phenomena better than those which have been previously proposed; for it is now ascertained, by repeated dissections both of the Kangaroo and Opossum, that there is no internal passage from the uterus to the marsupium; and if the genital outlet can be brought into contact with the orifice of the pouch in the dead Kangaroo by means of great stretching of the relaxed parts, yet such an action has never been witnessed in the living animal;* the tender embryo would be more liable to receive injury from the fore-paws; and these, from the absence of a thumb, could not so effectually ensure its passage as the lips, which can be opposed to each other. Lastly, the young one did not by any of its actions encourage the idea of its possessing the power of instinctively creeping up to the nipple. When the female had rested quiet for about half an hour, we again examined her, and found the young one not at the bottom of the pouch, but within two inches of the nipple; it was breathing strongly, and moving its extremities irregularly as before. I made an attempt to replace it on the nipple, but without success, and the mother was then released. On an examination two days afterwards the marsupium was found empty. Every portion of the litter was carefully searched, in the hopes of finding the foetus, but without success. The mother therefore, owing to the disturbance of the young one, had probably destroyed it. This was a result I had not expected, for the head keeper at the Zoological Farm had twice taken a mammary foetus from the nipple and pouch of the mother, soon after it had been deposited there, and when it did not exceed an inch in length, and it had each time again become attached to the nipple. I afterwards saw this foetus attached to the nipple, and it continued to grow, without having sustained any apparent injury from the separation, until the death of the mother, when it was nearly ready to leave the pouch. A similar result occurred to Mr. Collie.'

The young one observed by Mr. Collie (see *Zoological Journal*, vol. v., p. 239) was of nearly the size of the last and half the middle joint of one's little finger; and the flesh-coloured integuments were so transparent as to permit the larger coloured vessels and viscera to be seen through them. The extremities seemed completely formed, and its muscular power was testified by its efforts in sucking, during which it put every part of its body in motion. 'According to the testimony of the person,' continues Mr. Collie, 'who preserved the mother with this little one for me, the latter by no means passes the whole of its time with the lacteal papilla in its mouth, but has been remarked, more than once, without having hold of it. It has even been wholly removed from the sac to the person's hand, and has always attached itself anew to the teat. Yesterday,* on again looking at it, I gently pressed, with the tip of my finger, the head of the little one away from the teat of which it had hold, and continued pressing a little more strongly for the space of a minute altogether, when the teat, that had been stretched to more than an inch, came out of the young one's mouth, and showed a small circular enlargement at its tip, well adapting it for being retained by the mouth of the sucker. The opening of the mouth seemed closed in on both sides, and only sufficiently open in front to admit the slender papilla. After this I placed the extremity of the teat close to the mouth of the young, and held it there for a short time, without perceiving any decided effort to get hold of it anew; when I allowed the sac to close, and put the mother into her place of security. An hour afterwards the young one was observed still unattached, but in about two hours it had hold of the teat and was actively employed in sucking.'

Professor Owen then refers to a similar experiment tried with a mammary foetus about the size of a Norway rat by Mr. Morgan. This foetus, after two hours' separation from the nipple, regained its hold, and sustained no injury from the interruption of the supply of nourishment. Mr. Owen concludes, therefore, that the evidence adduced establishes the fact that the mammary foetus at a very early period is at least capable of sustaining a separation from the nipple; and although it may not at this stage of growth possess the power of regaining its hold by its own unaided efforts, it is far from being the inert and formless embryo that it has been described to be, resembling on the contrary, in its vital powers, the new-born young of the smaller *Mammalia* rather than the uterine foetus of a larger species at a period of development when such a foetus corresponds in size to a new-born Kangaroo; and although the latter possesses greater powers of action than the same-sized embryo of a sheep, and approximates more nearly in this respect to the new-born young of the rat, yet, Mr. Owen observes, it is evidently inferior to the latter. For, though enabled by the muscular power of its lips to grasp and adhere firmly to the nipple, its own unaided efforts seem incapable of drawing sustenance therefrom. The peculiar adaptation of a muscle, analogous to the cremaster, to the mammary gland, for the purpose of injecting the milk from the nipple into the mouth of the adherent foetus, has been demonstrated by Professor Geoffroy and Mr. Morgan; and Mr. Owen remarks that it can scarcely be supposed that the foetal efforts of suction should always be coincident with the maternal act of injection. If at any time this should not be the case, the consequences might be fatal from the forcible injection of milk into the larynx. To guard against this there is a special contrivance, first described by M. Geoffroy, the necessity for which appears to have been foreseen by John Hunter in his dissection of two small mammary foetuses of the Kangaroo for the especial purpose of showing the relation of the larynx to the posterior nares (Nos. 3731, 3734, 3735, Mus. Coll. Reg. Chir., Physiological series), in which, as Mr. Owen states, there are evidences that Hunter had anticipated most of the anatomical discoveries which have subsequently been made upon the embryo of the Kangaroo. The epiglottis and arytenoid cartilages are elongated and approximated, and the rima glottidis is thus situated at the apex of a cone-shaped larynx which projects, as in the *Cetacea*, into the posterior nares, where it is closely embraced by the muscles of the soft palate. The air-passage is thus completely separated from the fauces, and the injected milk passes in a divided stream on either side the larynx to the oesophagus.

'Thus aided and protected by modifications of structure,' continues Professor Owen, 'both in the system of the mother and in its own, designed with especial reference to each other's peculiar condition, and affording therefore the most irrefragable evidence of creative foresight, the feeble offspring continues to increase from sustenance exclusively derived from the mother for a period of about eight months. The young Kangaroo may then be seen frequently to protrude its head from the mouth of the pouch, and to crop the grass at the same time that the mother is browsing. Having thus acquired additional strength, it quits the pouch, and hops at first with a feeble and vacillating gait, but continues to return to the pouch for occasional shelter and supplies of food till it has attained the weight of ten pounds. After this it will occasionally insert its head for the purpose of sucking, notwithstanding another fœtus may have been deposited in the pouch, for the latter, as we have seen, attaches itself to a different nipple from the one which had been previously in use

1. The head of a mammary fœtus of a Kangaroo, about eight weeks old, dissected to show the relation of the larynx to the tongue and posterior nares. *a*, the epiglottis, drawn down out of the aperture in the soft palate; *b*, the cavity in the tongue for the reception of the nipple. 2. The elongated nipple, withdrawn from the mouth: the dotted line shows the extent to which it is grasped; it never extends into the œsophagus or stomach, as has been conjectured. (Owen.)

For the observations made by Professor Owen on the structure of the female generative organs in the other Marsupials, as compared with those of Oviparous, Ovoviviparous, and Viviparous animals, we must refer to his paper above quoted, our space not permitting us to do more than call the reader's attention to the fact that his inductions rest principally on the examination of those organs in *Didelphys dorsigera*, *Petaurus pygmæus*, *Petaurus Taguanoides*, *Dasypus viverrinus*, *Didelphys Virginiana*, *Hypsiprymnus Whitei*, and *Macropus major*. His remarks on the inferiority of the cerebral development of the Marsupials will be read with great interest as bearing on the structure and analogies of those organs, and other points of resemblance to the lower vertebrate classes, especially to the reptiles. 'Those marsupial quadrupeds which I have had an opportunity of observing alive in the Zoological Gardens,' says the professor (' and there are at present (1834) species of *Dasyurus*, *Didelphys*, *Phalangista*, *Petaurus*, *Hypsiprymnus*, *Macropus*, and *Phascalomys*), are all characterised by a low degree of intelligence; nor can I learn that they ever manifest any sign of recognition of their keepers or feeders. Another character, no less uniformly belonging to them, is the want of a power of uttering vocalised sounds. When irritated they emit a wheezing or snarling guttural sound; that of the *Dasyurus ursinus* is the clearest, and is the nearest approach to a growl. Mr. Harris however states that in addition to this noise, the Ursine Opossum utters a kind of hollow barking. The *Thylacinus cynocephalus*, or large Dog-faced Opossum, he observes, utters 'a short guttural cry, and appears exceedingly inactive and stupid, having, like the owl, an almost constant motion with the nictitating membrane of the eye.' The Wombat, when irritated, emits a loud hiss, which forcibly reminds one of that of the serpent. The noise emitted by the Kangaroo under similar circumstances is equally remote from a vocalised sound; the necessary apparatus for producing which, Cuvier long ago observed to be wanting in the larynx of this animal. It is interesting to find these analogies to the *Reptilia*, and more might be pointed out if it were not a comparison which merits a separate consideration.' The reader who would pursue his inquiries as to the generative system of the Marsupialia may also consult the previous writings of Daubenton, Rengger, and Leuckart. The museum of the Royal College of Surgeons will afford ample materials for following out the organization of this extraordinary group in the skeletons and preparations preserved in the Physiological Series of that noble institution. The following is the arrangement, based on the organization of the animals, proposed by Professor Owen in a paper read to the Zoological Society of London on the 8th and 22nd of January, 1839.

Classification of the Marsupialia.

Tribes.	Families.	Genera.	Subgenera.
SARCOPHAGA. Three kinds of teeth; canines long in both jaws; a simple stomach; no intestinum cæcum.	*Dasyuridæ* . .	Thylacinus. Dasyurus. Phascogale.	
. . . .	Extinct transitional forms.	Phascalotherium Thylacotherium } fossil.	
ENTOMOPHAGA. Three kinds of teeth in both jaws; simple stomach; a moderately long *intestinum cæcum*.	*Ambulatoria* . .	Myrmecobius.	
	Saltatoria . . .	Chœropus. Perameles.	
	Scansoria . . .	Didelphys . . .	Cheironectes.
CARPOPHAGA. Anterior incisors large and long in both jaws; canines inconstant; a simple stomach; a very long *intestinum cæcum*.	*Phalangistidæ* . .	Phalangista . . .	Cuscus. Pseudocheirus. Tapoa (Gray).
		Petaurus	Ascobates.
	Phascolarctidæ .	Phascolarctos.	
POEPHAGA. Anterior incisors large and long in both jaws, canines present in the upper jaw only or wanting; a complex stomach; a long *intestinum cæcum*.	*Macropodidæ* . .	Hypsiprymnus.	
		Macropus	Halmaturus. Macropus.
RHIZOPHAGA.* Two scalpriform incisors in both jaws; no canines; stomach with a special gland; cæcum short, wide, with a vermiform appendage.	*Phascolomyidæ* .	Phascolomys. Diprotodon (fossil)	

---

* The terms given to the tribes or primary groups of Marsupialia in the classification are not to be understood as strictly indicating the food of the species severally included therein, but only their general tendency to select for their support the substances implied by those designations.

We now proceed to give a succinct illustration of the genera and forms of the subgroups above mentioned.

Thylacinus. (Temminck.)

Generic Character.—Dental Formula:—Incisors $\frac{8}{6}$, Canines $\frac{1-1}{1-1}$, Molars $\frac{7-7}{7-7}$ = 46. The incisors are ranged in a semicircle, equal and separated in the middle in each jaw by a vacant space; the external incisor on each side is the smallest; the canines are of considerable size, curved and pointed like those of the Cats and Dogs; the last molars are armed with three obtuse tubercles, resembling those of the two groups of *Carnivora* last mentioned. *Toes* five on each fore-foot, and four on each hind-foot.

Example, *Thylacinus cynocephalus* (*Dasyurus cynocephalus* of Geoffroy; *Thylacinus Harrisii* of Temminck).

Description.—Size of a young wolf; the short smooth hair of a dusky yellowish-brown above, barred or banded on the lower part of the back and rump with about sixteen jet-black transverse stripes, broadest on the back and gradually tapering downwards, two of which extend a considerable way down the thighs. The ground colour on the back inclines to blackish gray. *Tail* much compressed and tapering to a point.

Habits and *Locality.*—Mr. Harris, from whose paper in 'Linn. Trans.' our description and figure are taken, states that this species, the largest of the Australian *Carnivora*, inhabits amongst caverns and rocks in the deep and almost impenetrable glens in the neighbourhood of the highest mountainous parts of Van Diemen's Land, where it probably preys upon the brush (Bush?) Kangaroo and various small animals that abound in those places. The individual from which the description and drawing were taken was caught in a trap baited with Kangaroo-flesh. It remained alive but a few hours, and during that period uttered the cry and presented the appearances quoted by Mr. Owen. In its stomach were found the partly-digested remains of a Porcupine Ant-Eater (*Echidna aculeata*). The vulgar names for this species are, the *Zebra Opossum*, *Zebra Wolf*, &c.

Thylacinus cynocephalus.

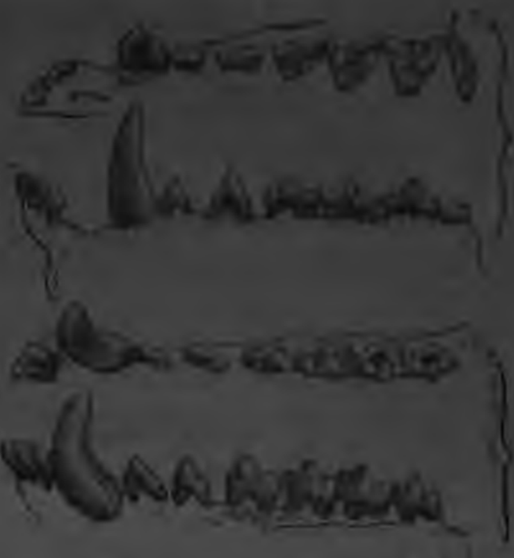
Dasyurus. (Geoffroy.)

Generic Character.—*Head* conical, very much pointed; gape very wide; ears moderate. *Toes* five on the fore-feet; on the hind-feet the great toe is reduced to a tubercle or is entirely absent.

Dental Formula:—Incisors $\frac{8}{6}$, Canines $\frac{1-1}{1-1}$, Molars $\frac{6-6}{6-6}$ = 42.

Example, *Dasyurus ursinus* (*Didelphis ursina* of Harris).

Description.—Head, body, legs, and upper part of the tail covered with long, coarse, black hair, irregularly marked with one or two blotches of white; in some specimens on the shoulders, in others on the throat or rump. Tail slightly prehensile, its under part bare. (Harris.)



Teeth of Dasyurus (Dasyurus ursinus).

Habits and Locality.—This species, which is very voracious, and burrows in the ground in Van Diemen's Land, is of the size of a badger. 'These animals,' says Mr. Harris, 'were very common on our first settling at Hobart Town, and were particularly destructive to poultry, &c. They however furnish the convicts with a fresh meal, and the taste was said to be not unlike veal. As the settlement increased, and the ground became cleared, they were driven from their haunts near the town to the deeper recesses of forests yet unexplored. They are however easily procured by setting a trap in the most unfrequented parts of the woods, baited with raw flesh; all kinds of which they eat indiscriminately and voraciously; they also, it is probable, prey on dead fish, blubber, &c., as their tracks are frequently found on the sands of the seashore. In a state of confinement they appear to be untameably savage; biting severely, and uttering at the same time a low yelling growl.

Dasyurus ursinus (Ursine Opossum). (Harris.)

A male and female, which I kept for a couple of months chained together in an empty cask, were continually fighting; their quarrels began as soon as it was dark (as they slept all day), and continued throughout the night almost without intermission, accompanied with a kind of hollow barking, not unlike a dog, and sometimes a sudden kind of snorting, as if the breath was retained a considerable time, and then suddenly expelled. The female generally conquered. They frequently sat on their hind parts, and used their fore-paws to convey food to their mouths. The muscles of their jaws were very strong, as they cracked the largest bones with ease asunder; and many of their actions, as well as their gait, strikingly resembled those of the bear. Its vulgar name is the Native Devil.'

The specimen in the garden of the Zoological Society was a snarling surly animal.

Mr. Owen's account of the dissection of a *Dasyurus macrurus*, or *Long-tailed Dasyurus* (*Spotted Martin* of Phillip's Voyage), will be found in the 'Zoological Proceedings' for 1835.

Phascogale. (*Temminck.*)

Generic Character.—Differing from *Dasyurus*, especially in its Dental Formula:—

$$\text{Incisors } \frac{8}{6}\text{; Canines } \frac{1-1}{1-1}\text{; Molars } \frac{7-7}{7-7} = 46.$$

Example, *Phascogale penicillata* (*Didelphis penicillatus* of Shaw, *Dasyurus penicillatus* of Geoffroy). Size rather larger than that of the Brown Rat (*Mus decumanus*). Tail very bushy. Fur uniform, ash-colour, whitish beneath, short, woolly, and very thick.

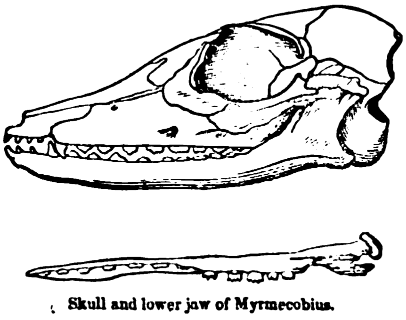
Habits and Locality.—This *Phascogale* lives on trees in New Holland.

Phascogale penicillata.

Myrmecobius. (Waterhouse.)

Generic Character.—*Fore-feet* with 5 toes; hind-feet with 4 toes, all free. *Head* elongated, snout produced; ears moderate, narrower, and subacute at the apex. *Body* slender. *Tail* moderate.

$$\text{Dental Formula:—Incisors } \frac{8}{6}\text{; Canines } \frac{1-1}{1-1}\text{; Pseudo-molars } \frac{3-3}{3-3}\text{; Molars } \frac{5-5}{6-6} = 52.$$

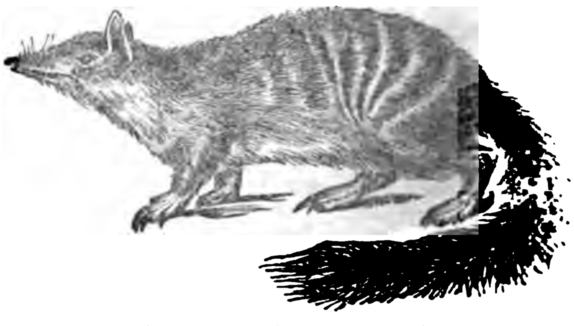


Skull and lower jaw of Myrmecobius.

Example, *Myrmecobius fasciatus.*

Description.—Fore part of the body reddish, gradually blended into the black, which is the prevailing colour of the posterior half, and which is adorned with nine white bands. Fur of two kinds. Under hair scanty and whitish grey; upper hair rather coarse, short, and adpressed on the anterior parts; long on the posterior and under parts; hairs on the anterior part of the back generally black at the base and fulvous at the apex; those on the head very short, brownish above, being composed of a mixture of black, fulvous, and a few white hairs; a few black hairs spring from the sides of the muzzle and under each eye; hair of the tail long and rather bushy; most of the hairs on the under part fulvous at the base and white at the tip; those on the under side of the tail generally black at the base and white at the apex. Length from nose to root of tail 10 inches; length of tail to the end of the hair 7 inches.

Habits and Locality.—Mr. Waterhouse, in his paper in the 'Transactions of the Zoological Society,' descriptive of this animal, gives the following account of the two specimens on which his description is founded. The first was procured by Lieutenant Dale of Liverpool, whilst on an exploring party in the interior of the country at the Swan River Settlement, and was discovered about ninety miles to the south-east of the mouth of that river. Two of these animals, according to Lieut. Dale, were seen within a few miles of each other; they were first observed on the ground, and on being pursued, both directed their flight to some hollow trees which were near. The party succeeded in capturing one of them; the other was unfortunately burnt to death in their endeavour to dislodge it by fumigating the hollow tree in which it had taken refuge. The country in which they were found abounded in decayed trees and ant-hills. Mr. Waterhouse was informed that the second individual was found in Van Diemen's Land (but he suspects some mistake here), and that others similar to it had been seen in the act of burrowing or digging at the roots of trees in search after insects. Their favourite haunts are stated to be in those situations in which the Port Jackson willow abounds.



Myrmecobius fasciatus. (Waterhouse.)

Mr. Waterhouse observes, that although in the structure of the skull *M. fasciatus* evinces an affinity to *Phascogale*, it differs from that genus in the want of a thumb to the hind-feet, and in the strength and larger size of the claws of the fore-feet, which are shaped somewhat like those in the genus *Herpestes*, and are evidently suited to burrowing. The fore-legs are also stouter in proportion, and the feet are stronger. In their narrow and pointed shape, the ears, he remarks, resemble those of *Perameles nasutus*, and differ from those of *Phascogale;* they also differ in being tolerably well clothed with hairs. Mr. Waterhouse imagines that in the present animal he can perceive a slight approach to the *Edentate Marsupialia*, or *Monotremes*, and he thinks that analogically it may be compared to the genus *Tupaia* among the true *Insectivora*, bearing a somewhat similar connection with *Echidna* and *Ornithorhynchus* to that which exists between the last-mentioned genus and the genera *Erinaceus* and *Mygale.* In conclusion he adds that it must be allowed that there is a greater dissimilarity in structure between the last-mentioned genus and the genera *Myrmecobius* and the *Monotremes*, than between *Tupaia* and *Mygale;* we are however prepared for this, by the comparatively sudden transitions from one form to another which we find in the *Marsupialia*, which group, it must be borne in mind, stands low in the grade of organization among the Mammalia. (*Zool. Trans.*, vol. ii.)

Chœropus. (*Ogilby.*)

On the 13th March, 1838, Mr. Ogilby exhibited to a meeting of the Zoological Society of London a drawing, made by Sir Thomas Mitchell, of a Marsupial animal found by that officer on the banks of the river Murray, during his late journey in the interior of New South Wales. Mr. Ogilby stated his original belief that the animal in question belonged to the genus *Perameles*, under which impression he had proposed to name it *Per. ecaudatus*, from its entire want of tail, a character found in no other species of the same group; but a drawing of the fore-foot, afterwards found by Sir Thomas Mitchell, and likewise exhibited to the Society on the present occasion, had considerably shaken this first opinion, and induced Mr. Ogilby to suspect that the animal may eventually form the type of a new genus. According to Sir Thomas Mitchell's drawing, and the notes which he took at the time of examining the specimen, it would appear that there were only two toes on the fore-feet, which were described as having been so perfectly similar to those of a pig, as to have procured for the animal the name of the pig-footed bandicoot, among the persons of the expedition.

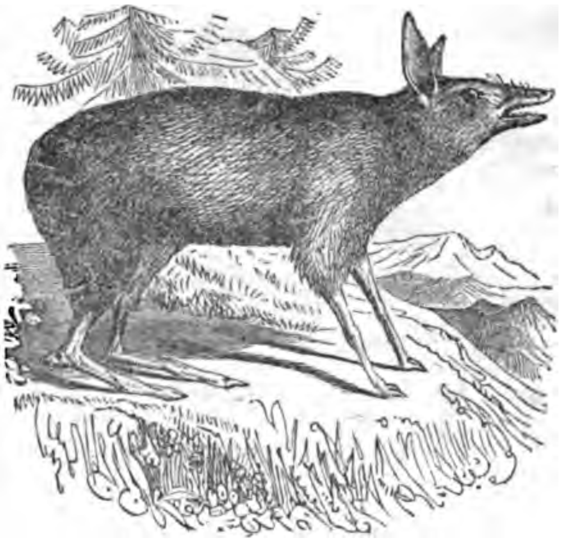
The drawing of the foot, in fact, very closely resembles that of the genus *Sus* in form and characters; two toes only are represented, short, and of equal length; but there is a swelling at the base of the first *phalanges*, which renders it probable that there may be two smaller ones behind. The *Perameles*, on the contrary, have three middle toes on the fore-feet, all of equal length, and armed with very long powerful claws, besides a small rudimentary toe very distinctly marked on each side. The form and character of the hind-feet were perfectly similar to those of the *Perameles*; as were also the teeth, as far as could be judged from the drawing, except that the canines did not appear to surpass the anterior molars in point of size. The ears were long, elliptical, and nearly naked; the head broad between the ears, and very much attenuated towards the muzzle; the body about the size of a small rabbit, and the fur very much of the same quality and colour as in that animal. Mr. Ogilby, after expressing his confidence in the fidelity of Sir Thomas Mitchell's drawings, and the care with which that gentleman assured him he had made the observation in question, expressed his belief that this animal would be found to constitute a new genus of Marsupials, and proposed for it the provisional name of *Chœropus*, in allusion to the described characters of the fore-feet.

The following is the notice of this animal inserted by Sir Thomas Mitchell in his journal, on the occasion of first discovering it. 'June 16, 1836. The most remarkable incident of this day's journey was the discovery of an animal of which I had seen only a head in a fossil state in the limestone caves of Wellington Valley, where, from its very singular form, I supposed it to belong to some extinct species. The chief peculiarity then observed was the broad head and very long slender snout, which resembled the narrow neck of a wide bottle; but in the living animal the absence of a tail was still more remarkable. The feet, and especially the fore-legs, were also singularly formed, the latter resembling those of a pig; and the marsupial opening was downwards, and not upwards, as in the Kangaroo and others of that class of animals. This quadruped was discovered by the natives on the ground; but on being chased, it took refuge in a hollow tree, from which they took it alive, all of them declaring that they had never before seen an animal of the kind. This was where the party had commenced the journey up the left bank of the Murray, immediately after crossing that river.' Such, Mr. Ogilby remarked, was all the information he possessed at present with regard to this singular animal; but Mr. Gould had promised to examine the original specimen on his arrival at Sydney, in the Museum of which town it had been deposited; and Mr. Ogilby therefore hoped that, through the kindness of that gentleman, he should shortly have it in his power to communicate a more detailed description of its form and characters to the Society. (*Zool. Proc.* 1838.)

Dental Formula:—

Jaw	Upper	4 incisors,	4 spurious molars,*	3 or 4 molars
		4 ,,	4 ,,	3 or 4 ,,
	Lower	3 incisors,	4 spurious molars,	3 or 4, perhaps 5
		3 ,,	4 ,,	3 or 4 ,, 5.

* The anterior of these might be termed canines.

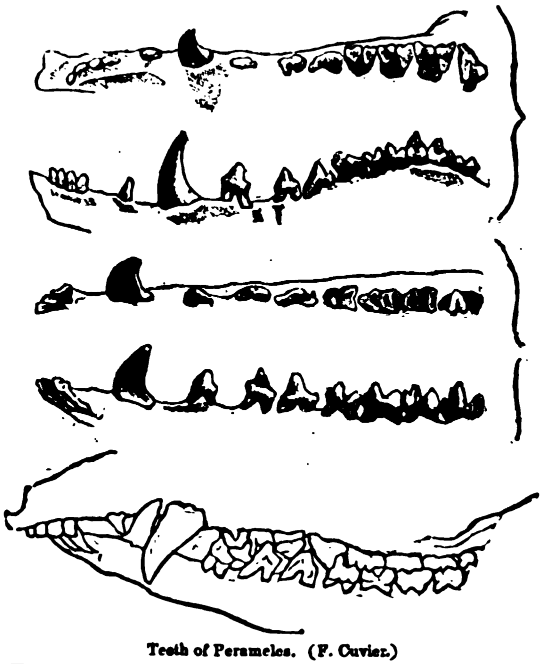


Chœropus ecaudatus.

Perameles. (*Geoffroy.*)

Generic Character.—*Head* elongated, pointed; ears moderate, hairy; posterior great-toes rudimentary, and the two succeeding toes united by the skin up to the nails, great toe and little toe of the fore-feet with the form of simple tubercles, so that they wear the appearance of having only three anterior toes.

Dental Formula:—Incisors $\frac{10}{6}$; canines $\frac{1-1}{1-1}$; molars $\frac{7-7}{7-7} = 48.$



Teeth of Perameles. (F. Cuvier.)

Example, *Perameles nasutus.*

Description.—*Head* very long; muzzle produced; nose prolonged above the jaw; fur grey-brown above and white beneath.

Locality.—Australia.

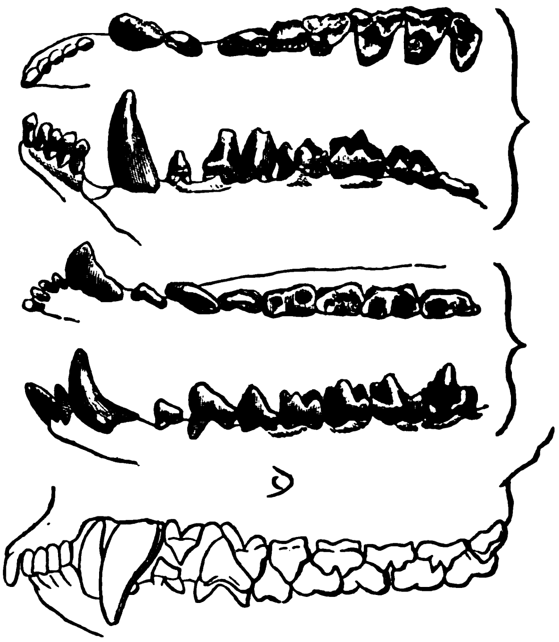
Mr. Gray, in characterizing a new species of Perameles (*Per. Gunnii*), very closely agreeing with *Per. nasutus*, but peculiar for its very short white tail, and in having several indistinct white bands over the haunches, stated that *Per Gunnii* inhabits Van Diemen's Land, where it frequents gardens, and commits great havoc amongst bulbous roots, which it is said to devour with avidity (*Zool. Proc.*, 1838). There is now (1839) a specimen of *Perameles Lagotis*, or *Rabbit Perameles*, from Swan River, in the garden of the Zoological Society in the Regent's Park.

Perameles nasutus.'

Didelphys. (*Linnæus.*)

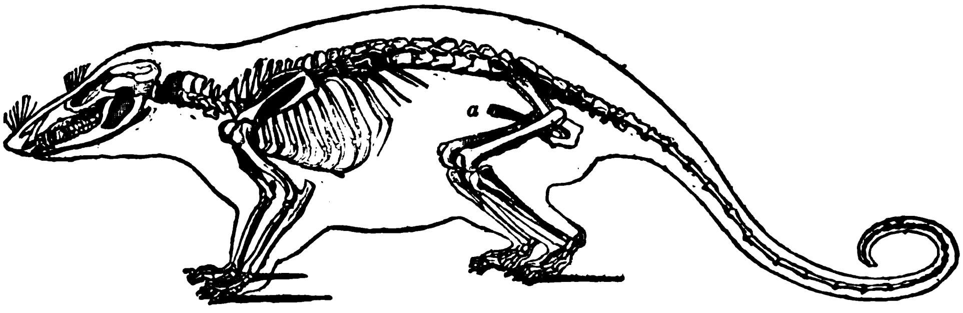
Generic Character.—Head very much pointed, gape wide, tongue rough with horny papillæ; ears large and naked; eyes small; tail long and tapering, flexible, and prehensile, with hair at the base only, the remaining part being covered with scales. Fore-feet with five toes, all armed with strong, sharp, curved claws; thumb of the hind-foot opposable and destitute of nail or claw, the other toes or fingers armed with claws like those of the fore-feet.

Dental Formula:—Incisors $\frac{10}{8}$; canines $\frac{1-1}{1-1}$; molars $\frac{7-7}{7-7}$ = 50.



Teeth of Didelphys Virginiana. (F. Cuvier.)

Geographical Distribution of the Genus.—America exclusively.



Skeleton of Didelphys Virginiana. *a*, the marsupial bones.

Example, *Didelphys Virginiana.*

Description.—Size that of a domestic cat. *Colour* dull white. *Hair* of two kinds; that which is lowest, a long fine woolly down, white at the base, brownish at the tip, through this pass the long hairs of a pure white on the head, neck, and upper parts of the body; the hair is short and close. Round each eye a brownish circle. Ears generally black at the base and yellowish at the tip. Whiskers long, partly white, partly reddish. Extremity of the nose flesh-coloured, with a tinge of yellow. Legs deep chestnut brown. Tail not so long as the body, covered at the base by long hairs, but only scantily furnished with bristles, which come out from between the whitish scales that protect it, for the greater part of its length.

Habits and Locality.—The Virginian Opossum is an arboreal animal, as might be expected from the structure of its posterior feet or hands especially. It appears to be to a certain degree carnivorous, for it preys upon insects and birds, and feeds also on fruits; but there is reason for believing that animal food forms its principal support, for it sometimes invades the farm-yards in its neighbourhood. According to Barton, the period of uterine gestation in this species is twenty-six days. It inhabits North America, and was, perhaps is, very abundant in the North of Mexico, and nearly throughout the United States, where it is called the opossum. In the *Perfect Description of Virginia* (1649), we find, in the catalogue of animals, '*Passonnes*—This beast hath a bagge under her belly, into which she takes her young ones, if at any time affrighted, and carries them away.' Lawson says, 'The *Possum* is found nowhere but in America. She is the wonder of all the land animals, being the size of a badger and near that colour. The female doubtless breeds her young at her teats, for I have seen them stick fast thereto, when they have been no bigger than a small rasberry, and seemingly inanimate. She has a paunch or false belly, wherein she carries her young, after they are from those teats, till they can shift for themselves. Their food is roots, poultry, or wild fruits. They have no hair on their tails, but a sort of a scale, or hard crust, as the beavers have. If a cat has nine lives, this creature surely has nineteen; for if you break every bone in their skin, and mash their skull, leaving them for dead, you may come an hour after, and they will be gone quite away, or perhaps you may meet them creeping away. They are a very stupid creature, utterly neglecting their safety. They are most like rats of anything. I have, for necessity in the wilderness, eaten of them. Their flesh is very white, and well tasted; but their ugly tails put me out of conceit with that fare. They climb trees as the racoons do. Their fur is not esteemed nor used, save that the Indians spin it into girdles and garters.' The tail appears to be not alone of use as an organ of prehension to the adult animal; for it is stated that the little ones when advanced in growth leap upon their mother's back if they are frightened, and, twisting their tails round hers, escape with her assistance the threatened danger.* In captivity the animal is sullen, snarling, and stupid.

---

* In the British Museum there is a stuffed specimen of Didelphys dorsigera beautifully prepared, with the young in this position.

Didelphys Virginiana (Virginian Opossum).

The French name *Sarigue* for the species of this genus is evidently a form of *Carigueya*, the Brazilian name for the genus. They are known in Paraguay under the name of *Micouré*, in the American Islands under that of *Manicou*, and in Mexico by the appellation of *Tlaquatzin*.

Cheironectes. (Illiger.)

Generic Character.—The complete dental formula of this subgenus does not appear to be known. The number of incisors is stated at ten above and eight below. *Head* rather pointed; ears naked, rounded; tail scaly, prehensile; an opposable thumb on the hind feet or hands, and the toes webbed.

Example, *Cheironectes palmatus* (*Cheironectes Yapock* of Desmarest; *Didelphis palmata* of authors).

Description.—Fur brown above, with three transverse bright grey bands, interrupted in the middle; white below. Size larger than that of the brown rat.

Habits and Locality.—The river Yapock, or Oyapock (the boundary that separates the French Settlements from Brazil), in Guyana, is the place where this species has been found. It swims with facility; indeed Buffon describes it under the name of *Petite loutre de la Guyane.*

Cheironectes palmatus.

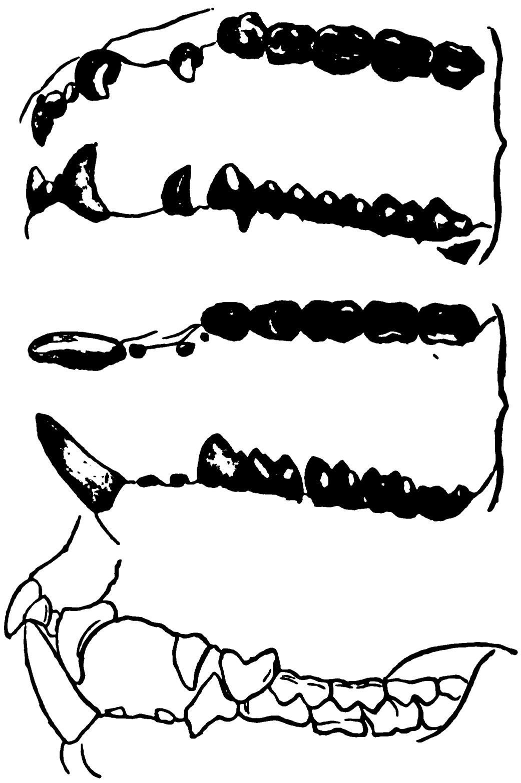
Phalangista. (Cuvier.)

Generic Character.—*Head* rather short; ears hairy; fur woolly and short; no extensible membrane between the anterior and posterior limbs; *tail* long, prehensile, sometimes without hair on its extremity.

Subgenus Phalangista, properly so called—Balantia (Illiger).

Tail prehensile, but covered with hair; ears long and erect.

Dental Formula:—Incisors $\frac{6}{2}$; canines $\frac{4}{0}$; pseudo-molars $\frac{4}{8}$; molars $\frac{8}{8}=40$.[*]



Teeth of Phalangista. (F. Cuvier.)

Example, *Phalangista vulpina.*

Description.—The following description of this species is given in Phillip's *Voyage*:—' Vulpine Opossum. This is not unlike the common fox in shape, but considerably inferior to it in respect to size, being from the point of the nose to the setting on of the tail only 26 inches; the tail itself 15 inches: the upper parts of the body are of a grisly colour, arising from a mixture of dusky and white hairs, with rufous yellow tinge; the head and shoulders partaking most of this last colour: round the eyes blackish: above the nostrils ten or twelve black whiskers, four inches or more in length: all the under parts of the body are of a

Phalangista vulpina (Vulpine Opossum).

---

[*] Lesson gives the dentition of Phalangista as, Incisors $\frac{6}{2}$, canines 0, molars $\frac{8-8}{7-7}=38$.

tawny buff colour, deepest on the throat, where the bottom of the hairs are rust colour: the tail is of the colour of the back for about one quarter of its length, from thence to the end black: the toes on the fore-feet are five in number, the inner one placed high up: on the hind-feet four toes only; with a thumb, consisting of two joints, without a claw, placed high up at the base of the inner toe: the whole foot serving the purpose of a hand, as observable in many of the Opossum genus. The legs are much shorter in proportion than those of the common fox: the ears about one inch and a half in length.' It is the *Phalanger Renard* of the French, *Bruno* of Vicq-d'Azyr, and *Whatapooroo* of the natives.

Locality.—New Holland; neighbourhood of Port Jackson.

Subgenus Cuscus. (*Lacépède.*)

Tail prehensile, but in great part naked and covered with rugosities; ears very short.

Dental Formula:—Incisors $\frac{6}{6}$; canines 0; molars $\frac{6-6}{8-8}$ = 40. (Lesson.)

Geographical Distribution of the Genus.—Peculiar to the Western Polynesia or Malaisia (Lesson).

Example, *Cuscus maculatus* (*Didelphis Orientalis* of Gmelin; *Cuscus Amboinensis* of Lacépède; *Phalangista maculata* of Geoffroy).

Description, Habits, and Locality.—This species, which is named Coescoes at the Moluccas, according to Valentyn, varies much in its colouring, with reference to sex and age. M. Lesson, who found it at Wagiou, where the natives call it *Scham-scham*, says that its fur, which is thick and woolly, is generally whitish, covered with isolated brown spots, sometimes running together. The same author states that its habits are slow and nocturnal, and that it lives on fruits in the equatorial forests of the great Molucca and Papuan Islands.

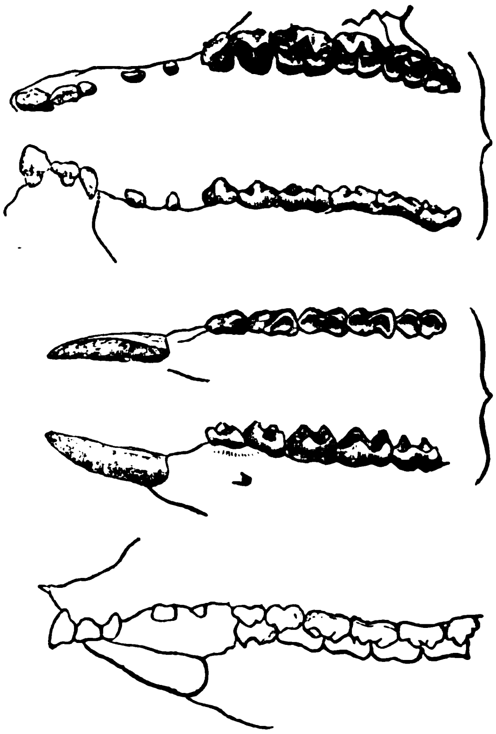
Cuscus maculatus.

Petaurus. (Shaw.)

Generic Character.—*Head* rather short; ears small and hairy; skin of the flanks extended between the anterior and posterior limbs, and covered with hair; tail not strictly prehensile.

Dental Formula:—Incisors $\frac{6}{2}$; canines $\frac{0-0}{0-0}$; molars $\frac{8-8}{7-7}$ = 38.

It will be observed that the number of lower molar teeth given in the cut amounts only to five, and consequently does not correspond with the formula above given, or with that stated by M. F. Cuvier himself, who makes the total number of teeth 22 in the upper jaw, and 16 in the lower, and the number of upper false molars 8, and of molars 8 also; the number of lower molars being 6 false and 8 true, 38 in all. He tells us that this form of dentition is taken from *Phalangista Cookii*, *Petaurus Taguanoides*, '*Le Phalanger didelphoide* or *Le Macraure* of M. Geoffroy, and a species which has no name.'



Teeth of Petaurus. (F. Cuvier.)

Mr. Bennett, who, in common with Cuvier, Desmarest, and Lesson, has placed the interesting species which we have chosen as the example under the genus *Petaurus*, remarks that M. F. Cuvier, relying solely on the discrepancy or agreement of the dentary systems, and putting entirely out of the question all consideration of other and essential points of structure, has reunited the old genus *Phalangista*, in order again to subdivide it into two incongruous and heterogeneous groups; in the one confounding two well marked species of flying *Petauri* not only with the climbing *Phalangistæ* of New Holland, but with the naked-tailed and strictly prehensile Couscous of the Moluccas; repaying the other group, which he had so unnecessarily dismembered, by the addition of a true *Phalangista*, whose only pretensions to such an association are made to depend on a somewhat similar arrangement of the teeth. 'By thus confining himself to a single character,' continues Mr. Bennett, 'he has broken up the regular series of affinities which connected together three marked but still closely allied gradations of form, to substitute an arrangement which has no other recommendation than the theoretic views of its author. In such a case we cannot hesitate in giving to the organs of locomotion, combined with the general habit, that precedence before those of mastication, which, under other circumstances, we are generally in the habit of conceding to the latter; and we feel the less repugnance to adopting this course, because it is admitted that the dentary formula is in these animals subject to some variation, and because zoologists are by no means agreed with respect to its exact definition. The teeth of the *Squirrel Petaurus* agree generally, according to M. F. Cuvier, with those of the Phalangistas. They are consequently 38 in number, 20 occupying the upper jaw, and 18 the lower. The former are divided by the same eminent naturalist into six incisors, four canines, two false molars, and eight true ones; the latter consisting of two incisors, and no canines, with eight false and as many true molars. The dentary character of the original species of *Petaurus*, which he takes as the type of his other group, differs chiefly in the total want of canine teeth; but we may here be permitted to observe that it appears to us somewhat doubtful how far those which are above enumerated as such truly deserve the name which has been applied to them. In every other respect the little creature in question perfectly agrees with the group of animals to which we have restored it; and which are at once characterised by the broad expansion of their skin on each side of the body, extending between the anterior and posterior limbs, as in the Flying Squirrels, to which indeed they bear a close resemblance. In common with nearly the whole of the mammiferous quadrupeds of the country which they inhabit, they possess the abdominal pouch which fixes their place in the system among the marsupial animals; and, as in many of these, the thumbs of the hind-feet are long and distinctly opposable to the sole. The other toes are four in number, and furnished with tolerably strong claws, of which the thumbs are destitute. The fore-feet have long radiating toes, the middle one of which is the longest, all armed with similar claws to those of the hind-feet. The tail is round, covered with loose hair, somewhat tapering towards the point, and not strictly prehensile, having no naked surface at its extremity beneath. In size the present species is about equal to the common Squirrel, and its tail is rather longer than its body. Its colour is delicately gray above, somewhat darker on the head, and white beneath. A black line passes from the point of the nose along the back towards the tail; and the lateral folds of the skin are bounded in front and on the sides by a similar band, which confounds itself gradually in the inside with the gray of the body, and is bordered at the outer margin by a fringe of white. The eyes are each placed in a spot of black, and a faint blackish line extends along the upper surface of the hinder limbs. The tail is also of a darker hue, especially towards its extremity.

Example, *Petaurus sciureus* (*Norfolk Island Flying Squirrel*, figured and described in Phillip's Voyage).

Description.—See above.

Petaurus Sciureus (Squirrel Petaurus).

Habits and Locality.—'During the day,' says Mr. Bennett, 'the animal generally remains quietly nestled in the hollows of trees, but becomes animated as night advances, and skims through the air, supported by its lateral expansions, half leaping, half flying from branch to branch, feeding upon leaves and insects. This peculiar mode of locomotion can scarcely be considered as a true flight, inasmuch as the cutaneous folds which serve the purposes of wings seem rather destined for the mere support of the animal in its long and apparently desperate leaps, than for raising it in the air and directing its course towards any given object. For this latter purpose they are indeed but little fitted by their structure, the want of proper muscles in a great measure incapacitating them from performing such offices as are dependent on volition. It may be doubted however whether these animals are entirely destitute of the power of exercising their will in their flight-like leaps. For the following anecdote bearing upon this subject we are indebted to our friend Mr. Broderip, who related it to us on unquestionable authority. On board a vessel sailing off the coast of New Holland was a Squirrel Petaurus, which was permitted to roam about the ship. On one occasion it reached the mast-head, and as the sailor who was despatched to bring it down approached, made a spring from aloft to avoid him. At this moment the ship gave a heavy lurch, which, if the original direction of the little creature's course had been continued, must have plunged it into the sea. All who witnessed the scene were in pain for its safety; but it suddenly appeared to check itself, and so to modify its career that it alighted safely on the deck.' Those that we have seen in captivity are in a state of somnolency all day; one kept at the Garden in the Regent's Park was formerly in the possession of the then marchioness of Cleveland. At night it was lively and active, and was perfectly tame, but rather shy. The species inhabits New South Wales, and is said to be abundant at the foot of the Blue Mountains. There seems to be no authority for the locality of Norfolk Island as a habitat of this very pretty little animal, excepting the figure and description in Phillip's Voyage above alluded to. The fur would be highly ornamental from its colour, softness, and beauty, as an article of dress.

Phascolarctos (*De Blainville*; *Lipurus*, *Goldfuss*; Amblotis, *Illiger*).

Generic Character.—*Body* stout. *Head* short, ears shaggy. *Limbs* rather short, robust, and nearly equal in length. *Toes* five on each fore-foot; the anterior toes divided into two groups for prehension, the thumb and the fore-finger being in one group, and the remaining three fingers in the other, the thumb of the posterior foot very large, but without a nail, and the two inner fingers united. *Tail* very short, almost null. Mr. Martin says that it differs from the *Wombat* in its dental formula, in which respect it closely resembles the Kangaroos.

Dental Formula:—Incisors $\frac{6}{2}$; canines $\frac{1-1}{0-0}$; spurious molars $\frac{1-1}{1-1}$; true molars $\frac{4-4}{4-4} = 30$.

The canines are small, and in the intermaxillary suture. The false molars are compressed and trenchant, but thicker than in *Hypsiprymnus*, the dentition of which, otherwise, that of the *Koala* resembles closely. The lower true grinders are narrower than the upper ones, and both quadricuspid.

Only one species is known, namely *Phascolarctos cinereus* (*Lipurus cinereus* of Goldfuss; *Phascolarctos fuscus* of Desmarest; *Phascolarctos Flindersii* of Lesson. The *Ashy Koala*).

Phascolarctos cinereus (Ashy Koala).

Description, Habits, and Locality.—As large as a dog of moderate size. Fur long, thick, rather coarse, and ashy brown, tufted ears rather lighter. It is said to have the gait and carriage of a young bear, to be arboreal in its habits, and to pass its life upon trees and in dens or holes which it hollows at their feet. Of its powers of climbing there can be no doubt; the structure of its extremities would lead to this inference, and actual observation has confirmed it. Its locality is New Holland, and we are enabled to give figures of the parent and young, taken by the kind permission of a friend, from a very accurate and beautiful drawing executed from the living animals, the first that were known in the colonies. They were brought in by natives to Colonel Paterson, then lieutenant-governor of the colony, from the Hat Hill district, to the southward of Port Jackson, in 1803. The native name 'Koala' is said to signify 'Biter.'

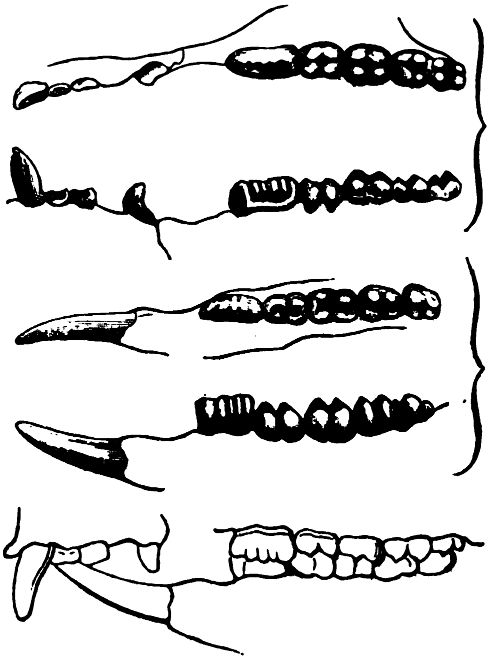
There are old and young stuffed specimens in the British Museum, and a stuffed specimen (Mr. Caley's) in the Museum of the Linnean Society.

The visceral anatomy will be found in Mr. Martin's paper 'On the anatomy of the *Koala*,' read to the Zoological Society in November, 1836 (*Zool Proc.*, 1836). It is chiefly remarkable for the enormous size and length of the cæcum.

Hypsiprymnus. (Illiger.)

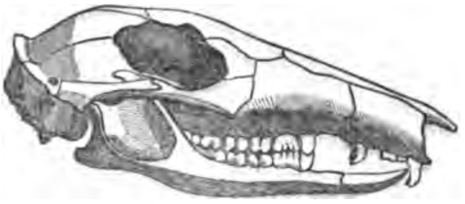
Generic Character.—Head elongated; ears large; upper lip cleft. *Tail* moderate, scaly, covered scantily with hairs. Two teats only in the ventral pouch of the females. Anterior feet five-toed, armed with obtuse nails; third toe of the hind-feet very robust, and armed with a very strong nail.

Dental Formula:—Incisors, $\frac{6}{2}$; canines, $\frac{1-1}{0}$; molars, $\frac{5-5}{5-5} = 30$.



Teeth of Hypsiprymnus. (F. Cuvier.)

Example, *Hypsiprymnus Potoroo* (*Macropus minor* of Shaw; *Potorous minimus* and *Kangurus Gaimardi* of Desmarest; *Hypsiprymnus Whitei* of Quoy and Gaimard; *Potoroo* of White, and *Kanguroo Rat* of Phillip's Voyage).



Skull of Hypsiprymnus.

Description.—Size of a rabbit; general colour grayish, reddish-brown above, whitish below; head triangular, ears large, tarsi very long; tail elongated, flexible, terminated by a pencil of hairs.

Habits and Locality.—The manners of the *Kangaroo Rat* are stated to be mild and timid; its food consists of vegetables, and it is said to burrow in the ground. New Holland is its locality, and Lesson says that it is not rare in the neighbourhood of Port Jackson, especially near the river Wera-mbia in the Blue Mountains.

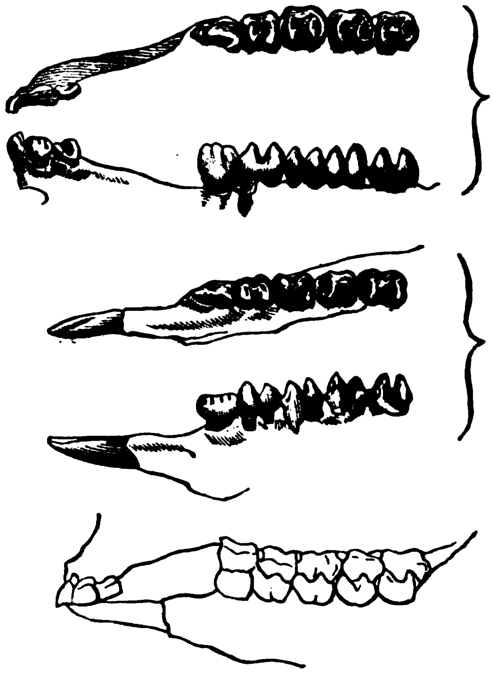
M. Lesson records two other species, and Mr. Ogilby de- ibes (*Zool. Proc.*, 1831) a fourth, *Hypsiprymnus setosus*, own in the colony of New South Wales by the native me of *Bettong Kangaroo.* The specimen described by r. Ogilby was believed to have been brought from Swan River. The last-named zoologist has also characterised six other new species. (*Zool. Proc.*, 1838.)

Hypsiprymnus Potoroo (Kangaroo Rat).

Subgenus Halmaturus. (*Illiger* in part.)

Generic Character.—Differing from the true Kangaroos in having shorter ears, a tail nearly naked, or only with a few hairs.

Dental Formula:—Incisors, $\frac{6}{2}$; canines, $\frac{0-0}{0-0}$; molars $\frac{5-5}{5-5} = 28$.



Teeth of Halmaturus. (F. Cuvier.)

Example, *Halmaturus elegans* (*Kangurus fasciatus* of Péron and Lesueur).

Description.—Colour mouse-gray, bounded transversely with reddish-brown on the back and loins. Size of a large hare.

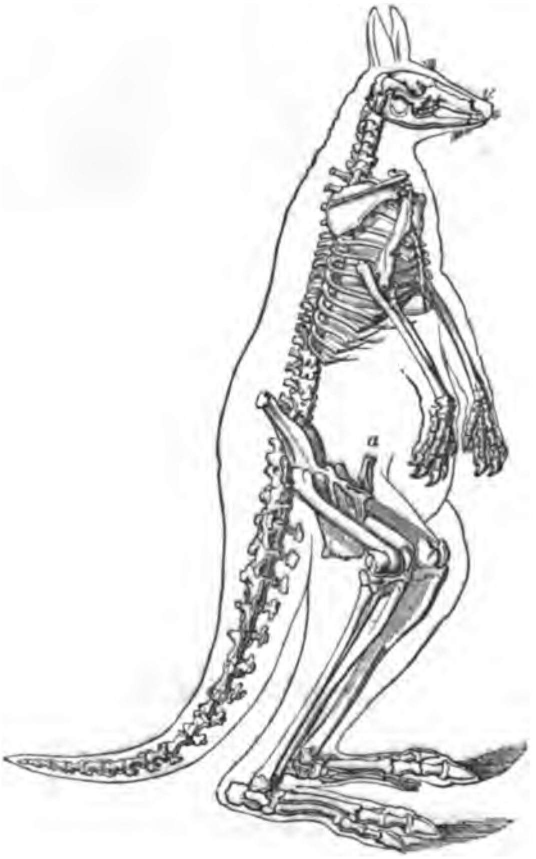
Habits and Locality.—Haunts under thick bushes, and is said to form subterranean galleries in the island of St. Pierre.

Subgenus Macropus (*Shaw;* Halmaturus of *Illiger* in part).

Generic Character.—Head elongated; ears very large; upper lip cleft; whiskers very short and few. Posterior limbs like those of *Hypsiprymnus*, but much longer and more robust. *Tail* long, triangular, very muscular.

Dental Formula:—Incisors $\frac{6}{2}$; canines $\frac{0-0}{0-0}$; molars $\frac{4-4}{4-4}=24$.

Example, *Macropus Major* of Shaw (*Kangurus labiatus* of Geoffroy; *Didelphis gigantea* of Gmelin; *The Kangaroo* of Cook).



Skeleton of Macropus major (the Great Kangaroo).
a, the marsupial bones.

Macropus major (the Great Kangaroo).

This extraordinary animal, discovered by Captain Cook, is now so well known, that a description, in addition to our illustrations and account of its animal economy at the beginning of this article, would be superfluous. Our countrymen pursued it in New Holland with greyhounds, and the leaps which it took surprised those who beheld it clear obstacles seven or eight feet high. In size it equals a sheep, some of the largest weighing 140 lbs., and the flesh is represented by those who have tasted it as being a little like venison. The species breeds pretty freely in this country, and has been kept with success in our parks.

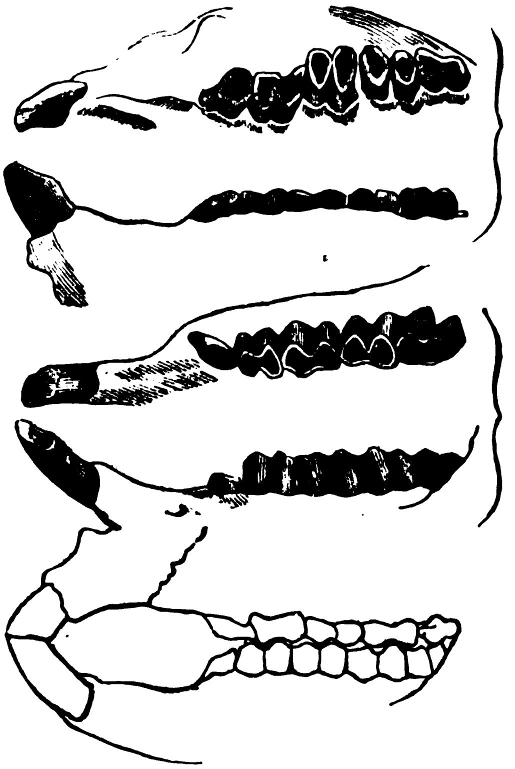
Locality.—New Holland.

There are several other species.

Phascolomys. (Geoffroy.)

Generic Character.—Body clumsy. *Head* large and bluff. Fore-*feet* with five toes, armed with crooked nails; hind-feet with four, and a little tubercle without a nail, in place of the great toe; indeed it may be said to have but four toes on the hind-feet. *Tail* nearly null.

Dental Formula:—Incisors $\frac{2}{2}$; canines $\frac{0-0}{0-0}$; molars $\frac{5-5}{5-5}=24$.



Teeth of Phascolomys, or Wombat (F. Cuvier), nearly of the natural size.

Example.—The only species known is *Phascolomys Wombat* (*Didelphis ursina* of Shaw; *The Wombat* of the natives, navigators, and naturalists).

Description.—From Lieut.-Col. Collins's 'Account of the English Colony of New South Wales' (1802), we select the following part of a description of a *Wombat* found on Cape Barren Island, abstracted from Bass's 'Journal:'—'The *Wombat*, or, as it is called by the natives of Port Jackson, the *Womback*, is a squat, short, thick, short-legged, rather inactive quadruped, with great appearance of stumpy strength, and somewhat bigger than a large turnspit dog. Its figure and movements, if they do not exactly resemble those of the bear, at least strongly remind one of that animal. Its length, from the tip of the tail to the tip of the nose, is thirty-one inches, of which its body takes up twenty-three and five-tenths. The head is seven inches and the tail five-tenths. Its circumference behind the fore-legs twenty-seven inches; across the thickest part of the belly thirty-one inches. Its weight by hand is somewhat between twenty-five and thirty pounds. The hair is coarse, and about one inch or one inch and five-tenths in length, thinly set upon the belly, thicker on the back and head, and thickest upon the loins and rump; the colour of it a light sandy brown of varying shades, but darkest along the back.' The head is large, flattish, and nearly triangular when viewed in front; the ears are sharp and erect; the eyes small and rather sunken than prominent, but quick and lively.

Habits and Locality.—From the same work we take the following account of the habits, &c. of this species:—'This animal has not any claim to swiftness of foot, as most men could run it down. Its pace is hobbling or shuffling, something like the awkward gait of a bear. In disposition it is mild and gentle, as becomes a grass-eater; but it bites hard, and is furious when provoked. Mr. Bass never heard its voice but at that time; it was a low cry between a hissing and a whizzing, which could not be heard at a distance of more than thirty or forty yards. He chased one, and with his hands under his belly suddenly lifted him off the ground without hurting him, and laid him upon his back along his arm like a child. It made no noise, nor any effort to escape, not even a struggle. Its countenance was placid and undisturbed, and it seemed as contented as if it had been nursed by Mr. Bass from its infancy. He carried the beast upwards of a mile, and often shifted him from arm to arm, sometimes laying him upon his shoulder, all of which he took in good part; until, being obliged to secure his legs while he went into the brush to cut a specimen of a new wood, the creature's anger arose with the pinching of the twine; he whizzed with all his might, kicked and scratched most furiously, and snapped off a piece from the elbow of Mr. Bass's jacket with his grass-cutting teeth. Their friendship was here at an end, and the creature remained implacable all the way to the boat, ceasing to kick only when he was exhausted. This circumstance seems to indicate that, with kind treatment, the Wombat might soon be rendered extremely docile; but let his tutor beware of giving him provocation, at least if he should be full grown. Besides Furneaux's Islands, the Wombat inhabits, as has been seen, the mountains to the westward of Port Jackson. In both these places its habitation is under ground, being admirably formed for burrowing; but to what depth it descends does not seem to be ascertained. According to the account given of it by the natives, the Wombat of the mountains is never seen during the day, but lives retired in his hole, feeding only in the night; but that of the islands is seen to feed in all parts of the day. His food is not yet well known; but it seems probable that he varies it, according to the situation in which he may be placed. The stomachs of such as Mr. Bass examined were distended with the coarse wiry grass, and he, as well as others, had seen the animal scratching among the dry ricks of sea-weed thrown up upon the shores, but could never discover what it was in search of. Now the inhabitant of the mountains can have no recourse to the sea-shore for his food, nor can he find there any wiry grass of the islands, but must live upon the food that circumstances present to him.'

A letter from James Hunter, Esq., Governor of the settlement, dated Sydney, New South Wales, August 5, 1798, and published in Bewick's 'Quadrupeds,' states, that this animal, there called *The Wombach*, was found upon an island on the coast of New South Wales, in lat. 40′ 36″ S., where considerable numbers were caught by the company of a ship which had been wrecked there on her voyage from Bengal to Port Jackson. The same communication relates that it had 'lately been discovered to be an inhabitant of the interior of this country also. The mountain natives call it the *Wombach*.'

The specimen dissected by Sir Everard Home in 1808 was brought from one of the islands in Bass's Straits, and lived as a domestic pet in the house of Mr. Clift for two years.

The individual dissected by Mr. Owen in May, 1836, had lived at the Gardens of the Zoological Society upwards of five years.

M. Lesson says that it lives in King Island and the Furneaux Islands, but that it does not exist in the neighbourhood of Port Jackson.

The anatomy of the Wombat will be found in Cuvier's 'Leçons d'Anatomie Comparée,' in Sir Everard Home's paper, 'Phil. Trans.,' 1808, and in Mr. Owen's memoir, 'Zool. Proc.,' 1836. The latter observes that the digestive organs in the abdominal cavity presented a development corresponding generally to that which characterises the same parts in the *phytiphagous Rodents*. It has a very short cæcum.

The flesh of the Wombat is said to be excellent. Mr. Hunter, the writer of the letter above quoted, terms it delicate meat, and some have remarked that the animal might be easily naturalised in this country.

The impression made upon us by Mr. Bass's account of the behaviour of the Wombat which he caught, and by one that we have seen in captivity, is, that the animal is of a low grade in point of intellect. In both cases, as long as there was no positive pain or disagreeable sensation, the animal was content, however new its situation might be. There was none of that anxiety and uneasiness which all animals of lively sense show when suddenly placed in new positions or in strange places; and indeed the following note is appended to Mr. Bass's account of the capture of his Wombat:—'The Kangooroo and some other animals in New South Wales were remarkable for being domesticated as soon as taken.' This may be one of the consequences of the low cerebral development generally to be observed in this group.

Phascolomys Wombat.

Fossil Marsupialia.

Besides the Fossil Opossum (*Didelphys Cuvieri*) of the Montmartre Gypsum, figured and described by Cuvier in the 'Annales du Museum,' and in his 'Ossemens Fossiles,' and the fossil *Dasyurus*, *Hypsiprymnus*, *Halmaturus*, *Phascolomys*, and *Kangaroo*, described by Mr. Clift and Cuvier and Mr. Pentland, from the Australian bone-caverns and bone breccia, there are some fossil forms now generally considered as belonging to the Marsupialia, which it will be necessary, on account of the great interest which attaches to them both geologically and zoologically, to mention more at length. We commence with those fossil jaws originally described as belonging to the Marsupialia, which were found at Stonesfield.

Thylacotherium. (Owen.)

In consequence of strong doubts* having been recently expressed by M. de Blainville, *from inspection of casts*, respecting the mammiferous nature of the fossil jaws found at Stonesfield, and assigned to the *Marsupialia* by Baron Cuvier, a paper 'On the Jaws of the *Thylacotherium Prevostii* from Stonesfield' was read before the Geological Society by Richard Owen, Esq., F.R.S., G.S., &c., Hunterian professor in the Royal College of Surgeons, on the 21st of November, 1838, being the first of two memoirs meeting the objections, and giving a detailed account of the fossils from a careful inspection of the originals. In this communication Mr. Owen confined his description to the jaws discovered at Stonesfield, characterised by having eleven molars in each ramus of the lower jaw. He commenced by observing that the scientific world possesses ample experience of the truth and tact with which the illusmens Cuvier formed his judgments of the affinities of an extinct animal from the inspection of a fossil fragment; and that it was only when so distinguished a comparative anatomist as M. de Blainville questioned the determinations, that it became the duty of those who possessed the means to investigate the nature of the doubts, and re-assure the confidence of geologists in their great guide.

---

* See 'Comptes Rendus,' 1838.

When Cuvier first hastily examined at Oxford, in 1818, one of the jaws described in Mr. Owen's paper, and in the possession of Dr. Buckland, he decided that it was allied to the Didelphys ('me semblèrent de quelque Didelphe'*); and when doubts were raised by M. Constant Prevost, in 1824,† relative to the age of the Stonesfield slate, Cuvier, from an examination of a drawing made for the express purpose, was confirmed in his former determination; but he added that the jaw differs from that of all known carnivorous Mammalia in having ten molars in a series in the lower jaw: ('il [the drawing] me confirme dans l'idée que la première inspection m'en avoit donnée. C'est celle d'un petit carnassier dont les mâchelières ressemblent beaucoup à celles des sarigues; mais il y a dix de ces dents en série, nombre que ne montre aucun carnassier connu.' *Oss. Foss.*, v., 349, note.) It is to be regretted that the particular data, with the exception of the number of the teeth, on which Cuvier based his opinion, were not detailed; but he must have been well aware that the grounds of his belief would be obvious, on an inspection of the fossil, to every competent anatomist; it is also to be regretted that he did not assign to the fossil a generic name, and thereby prevent much of the reasoning founded on the supposition that he considered it as belonging to a true Didelphys.

Mr. Owen then proceeded to describe the structure of the jaw; and he stated that having had in his possession two specimens of the *Thylacotherium Prevostii* belonging to Dr. Buckland, he had no hesitation in declaring that their condition is such as to enable any anatomist conversant with the established generalizations in comparative osteology, to pronounce therefrom not only the class but the more restricted group of animals to which they have belonged. The specimens plainly reveal, first, a *convex* articular condyle; secondly, a well-defined impression of what was once a broad, thin, high, and slightly recurved, triangular, coronoid process, rising immediately anterior to the condyle, having its basis extended over the whole of the interspace between the condyle and the commencement of the molar series, and having a vertical diameter equal to that of the horizontal ramus of the jaw itself: this impression also exhibits traces of the ridge leading forwards from the condyle and the depression above it, which characterises the coronoid process of the zoophagous marsupials; thirdly, the angle of the jaw is continued to the same extent below the condyle as the coronoid process reaches above it, and its apex is continued backwards in the form of a process; fourthly, the parts above described form one continuous portion with the horizontal ramus of the jaw, neither the articular condyle nor the coronoid being distinct pieces, as in reptiles. These are the characters, Mr. Owen believes, on which Cuvier formed his opinion of the nature of the fossil; and they have arrested the attention of M. Valenciennes in his endeavours to dissipate the doubts of M. de Blainville.‡

From the examination of a cast, M. de Blainville however has been induced to infer that there is no trace of a convex condyle, but in place thereof an articular fissure, somewhat as in the jaws of fishes; that the teeth, instead of being embedded in sockets, have their fangs confluent with or anchylosed to the substance of the jaws, and that the jaw itself presents evident traces of the composite structure.

In answer to the first of these positions, Mr. Owen stated that the portion of the true condyle which remains in both the specimens of Thylacotherium examined by Cuvier and M. Valenciennes, clearly shows that the condyle was convex, and not concave. It is situated a little above the level of the grinding surface of the teeth, and projects beyond the vertical line dropped from the extremity of the coronoid process, but not to the same extent as in the true Didelphys. In the specimen examined by M. Valenciennes the condyle corresponds in position with that of the jaw of the Dasyurus rather than the Didelphys: it is convex, as in mammiferous animals, and not concave, as in oviparous. The entire convex condyle exists in the specimen belonging to the other genus, *Phascolotherium*, now in the British Museum, but formerly in the cabinet of Mr. Broderip. Mr. Owen is of opinion that the existing angle or notch, either above or below the true articular condyle, has been mistaken for 'une sorte d'échancrure articulaire, un peu comme dans les poissons.'

The specimen of the half-jaw of the Thylacothere examined by M. Valenciennes, like that which was transmitted to Cuvier, presents the inner surface to the observer, and exhibits both the orifice of the dental canal and the symphysis in a perfect state. The foramen in the fossil is situated relatively more forward than in the recent Opossum and Dasyure, or in the Placental Insectivora, but has the same place as in the marsupial genus *Hypsiprymnus*. The symphysis is long and narrow, and is continued forward in the same line with the gently convex inferior margin of the jaw, which thus tapers gradually to a pointed anterior extremity, precisely as in the jaws of the Marsupial Insectivora. In the relative length of the symphysis, its form and position, the jaw of the Thylacotherium precisely corresponds with that of the Didelphys.

In addition however to these proofs of the mammiferous nature of the Stonesfield remains, and in part of their having belonged to Marsupialia, Mr. Owen stated that the jaws exhibit a character hitherto unnoticed by the able anatomists who have written respecting them, but which, if co-existent with a convex condyle, would serve to prove the marsupial nature of a fossil, though all the teeth were wanting.

In recent marsupials the angle of the jaw is elongated and bent inwards in the form of a process, varying in shape and development in different genera. In looking therefore directly upon the inferior margin of the marsupial jaw, we see, in place of the edge of a vertical plate of bone, a more or less flattened triangular surface or plate of bone extended between the external ridge and the internal process or inflected angle. In the Opossum this process is triangular and trihedral, and directed inwards with the point slightly curved upwards and extended backwards, in which direction it is more produced in the small than in the large species of Didelphys.

Now, observed Mr. Owen, if the process from the angle of the jaw in the Stonesfield fossil had been simply continued backwards, it would have resembled the jaw of an ordinary placental carnivorous or insectivorous mammal; but in both specimens of Thylacotherium, the half-jaws of which exhibit their inner or mesial surfaces, this process presents a fractured outline, evidently proving that when entire it must have been produced inwards or mesially, as in the Opossum.

Mr. Owen then described in great detail the structure of the teeth, and showed, in reply to M. de Blainville's second objection, that they are not confluent with the jaw, but are separated from it at their base by a layer of matter of a distinct colour from the teeth or the jaw, but evidently of the same nature as the matrix; and secondly, that the teeth cannot be considered as presenting an uniform compressed tricuspid structure, and being all of one kind, as M. de Blainville states, but must be divided into two series as regards their composition. Five if not six of the posterior teeth are quinque-cuspidate, and are *molares veri*; some of the *molares spurii* are tricuspid, and some bicuspid, as in the Opossums. An interesting result of this examination is the observation that the five cusps of the tuberculate molares are not arranged, as had been supposed, in the same line, but in two pairs placed transversely to the axis of the jaw, with the fifth cusp anterior, exactly as in the Didelphys, and totally different from the structure of the molares in any of the Phocæ, to which these very small Mammalia have been compared; and in reference to this comparison Mr. Owen again called attention to the value of the character of the process continued from the angle of the jaw, in the fossils, as strongly contradistinguishing them from the Phocidæ, in none of the species of which is the angle of the jaw so produced. The Thylacotherium differs from the genus Didelphys in the greater number of its molars, and from every ferine quadruped known at the time when Cuvier formed his opinion respecting the nature of the fossil. This difference in the number of the molar teeth, which Cuvier urged as evidence of the generic distinction of the Stonesfield mammiferous fossils, has since been regarded as one of the proofs of their Saurian nature; but the exceptions by excess to the number seven, assigned by M. de Blainville to the molar teeth in each ramus of the lower jaw of the insectivorous Mammalia, are well established, and have been long known. The insectivorous Chrysochlore, in the order Feræ, has eight molars in each ramus of the lower jaw; the insectivorous Armadillos have not fewer; and in one subgenus (Priodon) there are more than twenty molar teeth on each side of the lower jaw. The dental formulæ of the carnivorous Cetacea, again, demonstrate the fallacy of the argument against the mammiferous character of the Thylacotherium founded upon the number of its molar teeth. From the occurrence of the above exceptions in recent placental Mammalia, the example of a like excess in the number of molar teeth in the marsupial fossil ought rather to have led to the expectation of the discovery of a similar case among existing Marsupials, and such an addition to our zoological catalogues has, in fact, been recently made. In the Australian quadruped described by Mr. Waterhouse under the name of Myrmecobius an approximation towards the dentition of the Thylacotherium is exemplified, not only in the number of the molar teeth, which is nine on each side of the lower jaw in the Myrmecobius, but also in their relative size, structure, and disposition. Lastly, with respect to the dentition, Mr. Owen says it must be obvious to all who inspect the fossil and compare it with the jaw of a small Didelphys, that, contrary to the assertion of M. de Blainville, the teeth and their fangs are arranged with as much regularity in the one as in the other, and that no argument of the Saurian nature of the fossil can be founded on this part of its structure.

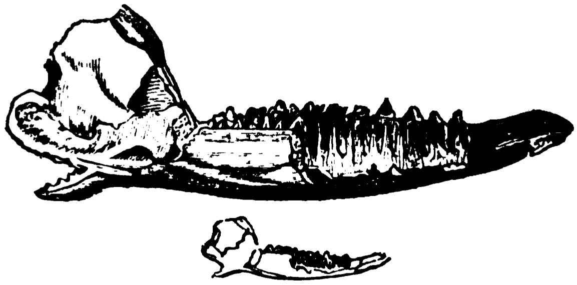
* 'Ossemens Foss.,' tom. v., p. 349.

† 'Annales des Sciences Nat.,' Avril, 1825; also the papers of Mr. Broderip and Dr. Fitton, in the 'Zoological Journal,' 1828, vol. iii., p. 408.

‡ 'Comptes Rendus,' 1838, Second semestre, No. 11, Sept. 10, p. 329, et seq.

With respect to M. de Blainville's assertion that the jaw is compound, Mr. Owen stated that the indication of this structure near the lower margin of the jaw of the Thylacotherium is not a true suture, but a vascular groove similar to that which characterises the lower jaw of Didelphys, Opossum, and some of the large species of Sorex. (*Geol. Proc.*)



Jaw of Thycalotherium Prevostii. Upper figure magnified.

Some discussion having ensued, in which Dr. Grant and Mr. Ogilby expressed opinions in support of M. de Blainville's views, Mr. Owen, on the occasion of reading, on the 9th of December following, his paper on *Phascalotherium*, being the second part of the 'Description of the Remains of Marsupial Mammalia from the Stonesfield slate,' gave a brief summary of the characters of the Thylacotherium, described in the first part of the memoir, and which he conceived fully proved the mammiferous nature of that fossil. He stated that the remains of the split condyles in the specimen demonstrate their original convex form, which is diametrically opposite to that which characterises the same part in all reptiles and all ovipara;—that the size, figure, and position of the coronoid process are such as were never yet witnessed in any except a zoophagous mammal endowed with a temporal muscle sufficiently developed to demand so extensive an attachment for working a powerful carnivorous jaw;—that the teeth, composed of dense ivory with crowns covered with a thick coat of enamel, are everywhere distinct from the substance of the jaw, but have two fangs deeply embedded in it;—that these teeth, which belong to the molar series, are of two kinds; the hinder being bristled with five cusps, four of which are placed in pairs transversely across the crown of the teeth, and the anterior or false molars, having a different form, and only two or three cusps—characters never yet found united in the teeth of any other than a zoophagous mammiferous quadruped;—that the general form of the jaw corresponds with the preceding more essential indications of its mammiferous nature. Fully impressed with the value of these characters, as determining the class to which the fossils belonged, Mr. Owen stated that he had sought in the next place for secondary characters which might reveal the group of Mammalia to which the remains could be assigned, and that he had found in the modification of the angle of the jaw, combined with the form, structure, and proportions of the teeth, sufficient evidence to induce him to believe that the *Thylacotherium* was a marsupial quadruped.

Mr. Owen then recapitulated the objections against the mammiferous nature of the *Thylacotherian* jaws from their supposed imperfect state, and repeated his former assertion that they are in a condition to enable these characters to be fully ascertained: he next reviewed, first the differences of opinion with respect to the actual structure of the jaw; and, secondly, with respect to the interpretation of admitted appearances.

1. As respects the structure.—It has been asserted that the jaws must belong to cold-blooded vertebrata, because the articular surface is in the form of an entering angle: to which Mr. Owen replied, that the articular surface is supported on a convex condyle, which is met with in no other class of vertebrata except in the Mammalia. Again, it is asserted that the teeth are all of an uniform structure, as in certain reptiles; but, on reference to the fossils, Mr. Owen stated that it will be found that such is not the case, and that the actual difference in the structure of the teeth strongly supports the mammiferous theory of the fossils.

2. With respect to the argument founded on an interpretation of structure, which really exists, the author showed that the *Thylacotherium* having eleven molars on each side of the lower jaw is no objection to its mammiferous nature, because among the placental Carnivora the *Canis Megalotis* has constantly one more grinder on each side of the lower jaw than the usual number; because the *Chrysochlore*, among the *Insectivora*, has also eight instead of seven molars in each ramus of the lower jaw; and the *Myrmecobius*, among the Marsupialia, has nine molars on each side of the lower jaw; and because some of the insectivorous *Armadillos* and zoophagous *Cetacea* offer still more numerous and reptile-like teeth, with all the true and essential characters of the mammiferous class. The objection to the false molars, having two fangs, Mr. Owen showed was futile, as the greater number of the spurious molars in every genus of the placental *Feræ* have two fangs, and the whole of them in the Marsupialia. If the ascending ramus in the Stonesfield jaws had been absent, and with it the evidence of their mammiferous nature afforded by the condyloid, coronoid, and angular processes, Mr. Owen stated that he conceived the teeth alone would have given sufficient proof, especially in their double fangs, that the fossils do belong to the highest class of animals.

In reply to the objections founded on the double fangs of the *Basilosaurus*, Mr. Owen said, that the characters of that fossil not having been fully given, it is doubtful to what class the animal belonged; and in answer to the opinion that certain sharks have double fangs, he explained that the widely bifurcate basis supporting the tooth of the shark is no part of the actual tooth, but true bone, and ossified parts of the jaw itself, to which the tooth is anchylosed at one part, and the ligaments of connection attached at the other. The form, depth, and position of the sockets of the teeth in the *Thylacothere* are precisely similar to those in the small Opossums. The colour of the fossils, Mr. Owen said, could be no objection to those acquainted with the diversity in this respect, which obtains in the fossil remains of Mammalia. Lastly, with respect to the *Thylacothere*, the author stated that the only trace of compound structure is a mere vascular groove running along its lower margin, and that a similar structure is present in the corresponding part of the lower jaw of some species of Opossum, of the *Wombat*, of the *Balæna antarctica*, and of the *Myrmecobius*, though the groove does not reach so far forwards in this animal; and that a similar groove is present near the lower margin, but on the outer side of the jaw, in the *Sorex Indicus*.

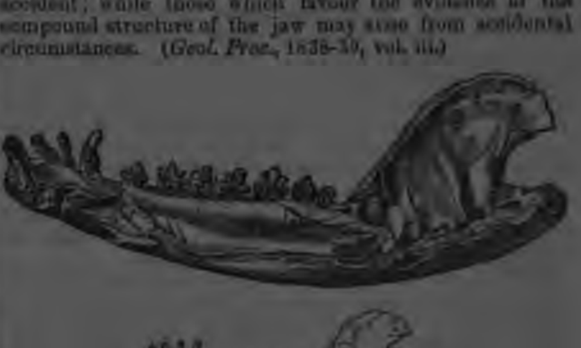
Phascolotherium. (Owen.)

Description of the Half-Jaw of the Phascolotherium.—This fossil is a right ramus of the lower jaw, having its internal or mesial surface exposed. It once formed the chief ornament of the private collection of Mr. Broderip, by whom it has since been liberally presented to the British Museum. It was described and figured by Mr. Broderip (1828, with the provisional name of *Didelphis Bucklandi* in the 'Zoological Journal,' and its distinction from the *Thylacotherium* clearly pointed out. The condyle of the jaw is entire, standing in bold relief, and presents the same form and degree of convexity as in the genera *Didelphys* and *Dasyurus*. In its being on a level with the molar teeth, it corresponds with the marsupial genera *Dasyurus* and *Thylacynus*, as well as with the placental zoophaga. The general form and proportions of the coronoid process closely resemble those in zoophagous Marsupials; but in the depth and form of the entering notch, between the process and the condyle, it corresponds most closely with the *Thylacynus*. Judging from the fractured surface of the inwardly reflected angle, that part had an extended oblique base, similar to the inflected angle of the *Thylacynus*. In the *Phascolotherium* the flattened inferior surface of the jaw, external to the fractured inflected angle, inclines outwards at an obtuse angle with the plane of the ascending ramus, and not at an acute angle, as in the *Thylacyne* and *Dasyurus*; but this difference is not one which approximates the fossil in question to any of the placental zoophaga; on the contrary, it is in the marsupial genus *Phascolomys*, where a precisely similar relation of the inferior flattened base to the elevated plate of the ascending ramus of the jaw is manifested. In the position of the dental foramen the *Phascolothere*, like the *Thylacothere*, differs from all zoophagous Marsupials and the placental *Feræ*; but in the *Hypsiprymnus* and *Phascolomys*, marsupial herbivora, the orifice of the dental canal is situated, as in the Stonesfield fossils, very near the vertical line dropped from the last molar tooth. The form of the symphysis, in the *Phascolothere*, cannot be truly determined; but Mr. Owen stated his opinion that it resembles the symphysis of the *Didelphys* more than that of the *Dasyurus* or *Thylacynus*.

Mr. Owen agrees with Mr. Broderip in assigning four incisors to each ramus of the lower jaw of the *Phascolothere*, as in the *Didelphys*; but in their scattered arrangement they resemble the incisors of the *Myrmecobius*. In the relative extent of the alveolar ridge occupied by the grinders, and in the proportions of the grinders to each other, especially the small size of the hindermost molar, the *Phascolothere* resembles the *Myrmecobius* more than it does the *Opossum*, *Dasyurus*, or *Thylacynus*; but in the form of the crown the molars of the fossil resemble the *Thylacynus* more closely than any other genus of Marsupials. In the number of the grinders the *Phascolothere* resembles the *Opossum* and *Thylacine*, having four true and three false in each maxillary ramus; but the *molares veri* of the fossil differ from those of the *Opossum* and *Thylacothere* in wanting a pointed tubercle on the inner side of the middle large tubercle, and in the same transverse line with it, the place being occupied by a ridge which extends along the inner side of the base of the crown of the true molars, and projects a little beyond the anterior and posterior smaller cusps, giving the quinquecuspid appearance to the crown of the tooth. This ridge, which in *Phascolotherium* represents the inner cusps of the true molars in *Didelphys* and *Thylacotherium*, is wanting in *Thylacynus*, in which the true molars are more simple than in the *Phascolothere*, though hardly less distinguishable from the false molars. In the second true molar of the *Phascolothere* the internal ridge is also obsolete at the base of the middle cusp, and this tooth presents a close resemblance to the corresponding tooth in the *Thylacine*; but in the *Thylacine* the two posterior molars increase in size, while in the *Phascolothere* they progressively diminish, as in the *Myrmecobius*. As the outer sides of the grinders in the jaw of the *Phascolothere* are imbedded in the matrix, we cannot be sure that there is not a smaller cuspidated ridge sloping down towards that side, as in the crowns of the teeth of the *Myrmecobius*. But assuming that all the cusps of the teeth of the *Phascolothere* are exhibited in the fossil, still the crowns of these teeth resemble those of the *Thylacine* more than they do those of any placental *Insectivore* or *Phoca*, if even the form of the jaw permitted a comparison of it with that of any of the Seal tribe. Connecting then the close resemblance which the molar teeth of the *Phascolotherium* bear to those of the *Thylacynus* with the similarities of the ascending ramus of the jaw, Mr. Owen is of opinion that the Stonesfield fossil was nearly allied to *Thylacynus*, and that its position in the marsupial series is between *Thylacynus* and *Didelphys*. With respect to the supposed compound structure of the jaw of the *Phascolotherium*, Mr. Owen is of opinion that, of the two linear impressions which have been mistaken for *harmoniæ*, or toothless sutures, one, a faint shallow linear impression continued from between the antepenultimate and penultimate molars obliquely downwards and backwards to the foramen of the dental artery, is due to the presence of a small artery, and he stated that he possessed the jaw of a *Didelphys Virginiana* which exhibits a similar groove in the same place. Moreover this groove in the *Phascolothere* does not occupy the same relative position as any of the contiguous margins of the opercular and dentary pieces of a reptile's jaw. The other impression in the jaw of the *Phascolotherium* is a deep groove continued from the anterior extremity of the fractured base of the inflected angle obliquely downwards to the broken surface of the anterior part of the jaw. Whether this line be due to a vascular impression or an accidental fracture is doubtful; but as the lower jaw of the *Wombat* presents an impression in the precisely corresponding situation, and which is undoubtedly due to the presence of an artery, Mr. Owen conceives that this impression is also natural in the *Phascolothere*, but equally unconnected with a compound structure of the jaw; for there is not any suture in the compound jaw of a reptile which occupies a corresponding situation.

The most numerous, the most characteristic, and the best-marked sutures in the compound jaws of a reptile are those which define the limits of the coronoid, articular, angular, and surangular pieces, and which are chiefly conspicuous on the inner side of the posterior part of the jaw. Now the corresponding surface of the jaw of the *Phascolothere* is entire, yet the smallest trace of sutures, or of any indication that the coronoid or articular processes were distinct pieces, cannot be detected; these processes are clearly and indisputably continuous, and confluent with the rest of the ramus of the jaw. So that where sutures ought to be visible, if the jaw of the *Phascolothere* were composite, there are none; and the hypothetical sutures that are apparent do not agree in position with any of the real sutures of an oviparous compound jaw.

Lastly, with reference to the philosophy of pronouncing judgment on the Saurian nature of the Stonesfield fossils from the appearance of sutures, Mr. Owen offered one remark, the justness of which, he said, would be obvious alike to those who were and to those who were not conversant with comparative anatomy. The accumulative evidence of the true nature of the Stonesfield fossils, afforded by the shape of the condyle, coronoid process, angle of the jaw, different kinds of teeth, shape of their crowns, double fangs, implantation in sockets,—the appearances, he repeated, presented by these important particulars cannot be due to accident; while those which favour the evidence of the compound structure of the jaw may arise from accidental circumstances. (*Geol. Proc.*, 1838-39, vol. iii.)



Jaw of Phascolotherium Bucklandii. Upper figure magnified.

A paper was afterwards read, entitled 'Observations on the Structure and Relations of the presumed Marsupial Remains from the Stonesfield oolite,' by William Ogilby, Esq., F.G.S.

These observations were intended by the author to embody only the most prominent characters of the fossils, and those essential points of structure in which they are necessarily related to the class of mammifers or of reptiles respectively. For the sake of putting the several points clearly and impartially, he arranged his observations under the two following heads:—

1. The relations of agreement which subsist between the fossils in question and the corresponding bones of recent Marsupials and Insectivora.

2. The characters in which the fossils differ from those families. Mr. Ogilby confined his remarks to Marsupialia and Insectivora, because it is to those families only of Mammifers that the fossils have been considered by anatomists to belong; and to the interior surface of the jaw, as the exterior is not exhibited in any of the fossil specimens.

1. In the general outline of the jaws, more especially in that of the *Didelphys* (*Phascolotherium*) *Bucklandii*, the author stated that there is a very close resemblance to the jaw in recent Insectivora and insectivorous Marsupials; but he observed that with respect to the uniform curvature along the inferior margin, Cuvier has adduced the same structure as distinctive of the Monitors, Iguanas, and other true Saurian reptiles; so that whatever support these modifications of structure may give to the question respecting the marsupial nature of the Stonesfield fossils, as compared with other groups of Mammals, they do not affect the previous question of their mammiferous nature, as compared with reptiles and fishes. The fossil jaws, Mr. Ogilby said, agree with those of Mammals, and differ from those of all recent reptiles, in not being prolonged backward behind the articulating condyle; a character, in conjunction with the former relation, which would be, in this author's opinion, well-nigh incontrovertible, if it were absolutely exclusive; but the extinct Saurians, the *Pterodactyles*, *Ichthyosauri*, and *Plesiosauri*, cotemporaries of the Stonesfield fossils, differ from their recent congeners in this respect, and agree with Mammals. Mr. Ogilby is of opinion that the condyle is round both in *D. Prevostii* and *D. Bucklandii*, and is therefore a very strong point in favour of the mammiferous nature of the jaws. The angular process, he said, is distinct in one specimen of *D. Prevostii*, and, though broken off in the other, has left a well-defined impression; but that it agrees in position with the Insectivora, and not the Marsupialia, being situated in the plane passing through the coronoid process and the ramus of the jaw. In the *D. Bucklandii*, he conceived, the process is entirely wanting; but that there is a slight longitudinal ridge partially broken, which might be mistaken for it, though placed at a considerable distance up the jaw, or nearly on a level with the condyle, and not at the inferior angular rim of the jaw. He is therefore of opinion that the *D. Bucklandii* cannot be properly associated either with the Marsupial or Insectivorous Mammals. The composition of the teeth, he conceives, cannot be advanced successfully against the mammiferous nature of the fossils, because animal matter preponderates over mineral in the teeth of the great majority of the Insectivorous *Cheiroptera*, as well as in those of the *Myrmecobius* and other small Marsupials. In the jaw of the *D. Prevostii* Mr. Ogilby cannot perceive any appearance of a dentary canal, the fangs of the teeth, in his opinion, almost reaching the inferior margin of the jaw, and being implanted completely in the bone; but in the *D. Bucklandii* he has observed, towards the anterior extremity of the jaw, a hollow space filled with foreign matter, and very like a dentary canal. The double fangs of the teeth of *D. Prevostii*, and probably of *D. Bucklandii*, he said, are strong points of agreement between the fossils and mammifers in general; but that double roots necessarily indicate, not the mammiferous nature of the animal, but the compound form of the crowns of the teeth.

2. With respect to the most prominent characters by which the Stonesfield fossils are distinguished from recent mammals of the insectivorous and marsupial families, Mr. Ogilby mentioned, first, the position of the condyle, which is placed in the fossil jaws in a line rather below the level of the crowns of the teeth; and he stated that the condyle not being elevated above the line in the *Dasyurus Ursinus* and *Thylacinus Harrisii*, is not a valid argument, because those Marsupials are carnivorous. The second point urged by the author against the opinion that the fossils belonged to insectivorous or marsupial mammifers, is in the nature and arrangement of the teeth. The number of the molars, he conceives, is a secondary consideration; but he is convinced that they cannot be separated in the fossil jaws into true and false, as in Mammalia; the great length of the fangs, equal to at least three times the depth of the crowns, he conceives, is a strong objection to the fossils being placed in that class, as it is a character altogether peculiar and unexampled among mammals; the form of the teeth also, stated, cannot be justly compared to that of any known ies of marsupial or insectivorous mammifer, being, in the author's opinion, simply tricuspid, and without any appearance of interior lobes. As to the canines and incisors, Mr. Ogilby said that the tooth in *D. Bucklandii*, which has been called a canine, is not larger than some of the presumed incisors, and that all of them are so widely separated as to occupy full five-twelfths of the entire dental line, whilst in the *Dasyurus viverrinus* and other species of insectivorous Marsupials they occupy one-fifth part of the same space. Their being arranged longitudinally in the same line with the molars, he conceives, is another objection, because, among all mammals, the incisors occupy the front of the jaw, and stand at right angles to the line of the molars. With respect to the supposed compound structure of the jaw, Mr. Ogilby offered no formal opinion, but contented himself with simply stating the appearances: he nevertheless objected to the grooves being considered the impression of blood-vessels, though he admitted that the form of the jaws is altogether different from that of any known reptile or fish.

From a due consideration of the whole of the evidence, Mr. Ogilby stated, in conclusion, that the fossils present so many important and distinctive characters in common with mammals on the one hand, and cold-blooded animals on the other, that he does not think naturalists are justified at present in pronouncing definitively to which class the fossils really belong. (*Geol. Proc.*, 1838-39, vol. iii.)

On the 9th of January, 1839, Mr. Owen proved, in a paper read to the Geological Society, that the so-called *Basilosaurus* of Dr. Harlan, upon which M. de Blainville and the other objectors, thinking it to be a fossil reptile with double-fanged teeth, had relied so strongly as an argument for the non-mammiferous nature of the Stonesfield jaws, is no Saurian at all, but a mammiferous animal forming a most interesting link between the carnivorous and herbivorous *Cetacea;* and in compliance with the suggestion of Dr. Harlan, who, having compared with Mr. Owen the microscopic structure of the teeth of the *Basilosaurus* with those of the *Dugong* and other animals, admitted the correctness of the inference of its mammiferous nature.—Mr. Owen proposed to substitute for the name of *Basilosaurus* that of *Zeuglodon*. [WHALES.]

Among the fossil remains collected by Sir Thomas Livingstone Mitchell, in the caves of Wellington Valley, Australia, and which are now deposited in the museum of the Geological Society of London, Professor Owen describes the following genera and species:—

Macropus.

Macropus Atlas, at least one-third larger than the *Macropus major*, the largest known existing species of Kanguroo, approaching in the great size of its permanent spurious molar to *Hypsiprymnus*.

Macropus Titan, as large as the preceding, but differing chiefly in the smaller size of the permanent spurious molar, which in this respect more nearly corresponds with the existing *Macropus major*.

Hypsiprymnus.

An undetermined species, rather larger than any of the three species with whose crania Mr. Owen has had the opportunity of comparing them. There is no evidence, according to him, that it agrees with any existing species.

Phalangista.

A species differing from *Phalangista Vulpina* in having the spurious molar of relatively smaller size, and the second molar narrower; the symphysis of the lower jaw is also one line deeper in the fossil. Mr. Owen states that there is no proof that it corresponds with any existing species; but, he adds, that a comparison of the fossils with the bones of these species (which are much wanted in our osteological collections) is obviously necessary to establish the important fact of the specific difference or otherwise of the extinct Phalanger.

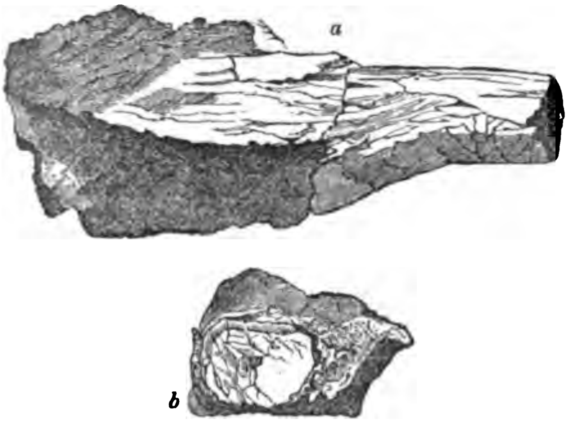
Phascolomys.

Phasolomys Mitchellii, a little larger, probably, than the existing Wombat.

Diprotodon. (N. G. Owen.)

Mr. Owen applies this name to the genus of *Mammals* represented by the anterior extremity of the right ramus of the lower jaw, with a single large procumbent incisor, of which we give a reduced figure below (*a*, *b*). It had been formerly conjectured to belong to the Dugong, but the incisor resembles the corresponding tooth of the Wombat;

in its enamelled structure and position (*b*), and the section of the Wombat's teeth. It differs however in the quadrilateral figure of its transverse section, in which it corresponds with the inferior incisors of the Hippopotamus.



Anterior extremity of the right ramus, lower jaw, of Diprotodon.
a, profile. (Owen.)

Dasyurus.

Dasyurus laniarius, closely resembling *Dasyurus Ursinus*, but differing from it in being one-third larger, and in having the canines or laniaries of proportionately larger size. Another specimen leads Mr. Owen to doubt whether it is the lower jaw of the *Dasyurus laniarius*, or of some extinct marsupial carnivore of an allied but distinct species.

The general result of the examination of the remains found in the Wellington Valley bone-caves are,—1st. That the fossils are not referrible to any known extra-Australian genus of mammals. 2nd. That the fossils are not referrible, from the present evidence, to any existing species of Australian mammal. 3rd. That the greater number certainly belong to species either extinct or not yet discovered living in Australia. 4th. That the extinct species of *Macropus*, *Dasyurus*, and *Phascolomys*, especially *Macropi Atlas* and *Titan*, are larger than the largest known existing species. 5th. That the remains of the saltatory animals, as the *Macropi* and *Hypsiprymni*, are all of young individuals; while those of the burrowing Wombat, the climbing Phalanger, and the ambulatory Dasyure, are the remains of adults. (Owen, in Mitchell's *Three Expeditions into the Interior of Eastern Australia*, &c.)

Dr. Buckland observes, that the discovery of the *Marsupialia*, both in the secondary and tertiary formations, shows that this order, so far from being of more recent introduction than other orders of Mammalia, is in reality the first and most antient condition under which animals of this class appeared upon our planet;—that, as far as we know, it was their only form during the secondary period;—that it was co-existent with many other orders in the early parts of the tertiary period; and that its geographical distribution in the present creation is limited to North and South America, and to New Holland, with the adjacent islands. (*Bridgewater Treatise*.)

MARSUPIOCRINITES, a genus of Crinoidea, recently proposed by Professor Phillips for some remarkable fossils noticed by Mr. Murchison in the strata of the Silurian system. (*The Silurian System*, pl. 18, f. 3.) The arms are formed of two rows of calcareous plates.

MARSUPIOCRINITES. [Encrinities, vol. ix., p. 393.]

MARSUPITES, a fossil genus of *Echinodermata*, established by Miller in his work on the Crinoidea. In many respects it resembles the Crinoidea, but has no stem. [Encrinites, vol. ix., p. 393.] It belongs to the chalk.

MARTABAN. [Tenasserim.]

MARTEL, CHARLES. [Charles Martel.]

MARTELLO TOWER, a circular building of masonry, generally two stories high; the lower story is divided into chambers for the reception of stores, and the upper serves as a casemate for troops: the roofs are vaulted, and that of the upper story is shell-proof. The wall of the building terminates above in a parapet; and, on the terreplein of the roof, are placed pieces of artillery which rest on platforms of timber traversing on pivots, so that the guns are capable of being fired in any direction. The entrances are at a considerable height above the ground, and over these are machicolations. The whole work is generally surrounded by a ditch and glacis.

It is probable that the name of such works should be Mortella Towers, since it is supposed to have been derived from that of a fort in Mortella (Myrtle) Bay, Corsica, which after a gallant resistance was taken in 1794 by a British naval force. Several such towers were, during the late war, built on the coasts of this country, in Jersey, and elsewhere: but most of them have, since the peace, been taken down, from an opinion that the defence which could be made from them, in the event of an invasion, would not be adequate to the expense of keeping them in repair.

MARTEN, or MARTIN (Mammalogy), the name of a carnivorous quadruped (*Mustela Martes*, Linn.), of the Weasel family. [Weasel.]

MARTHA'S VINEYARD. [Massachusetts.]

MARTIAL LAW is a series of regulations made to preserve order and discipline in the army, and enforced by the prompt decisions of courts-martial; this is generally however called military law. During the existence of a rebellion, when, in consequence of the ordinary processes of general law becoming ineffectual for the security of life and property in any province or state, the legislature has appointed that a military force shall be employed to suppress the disorders and secure the offenders—and when the trial of the latter takes place according to the practice of military courts, that province or state is said to be subject to martial law.

On the occurrence of such a calamity in any part of the British dominions, the two houses of parliament, jointly with the crown, determine that a temporary suspension of the Habeas Corpus Act shall take place. This measure is, of course, adopted only in cases of great emergency, on account of the abuses to which it may give rise; and the necessity of it and the time of its duration are always stated in the provisions of the decree. The act by which martial law was declared in Ireland during the Rebellion in 1798 may be seen in Tytler's *Essay on Military Law*, Appendix, No. 6.

In merely local tumults the military commander is called upon to act with his troops only when the civil authorities have failed in preserving peace; and the responsibility of employing soldiers on such occasions falls entirely upon the magistrate. The military officer must then effect by force what by other means could not be effected; and, for the consequences, the officer can be answerable only to a military court or to the parliament of the nation.

The constitution of this country permits a military law for the government of the army, even in times of internal tranquillity, to co-exist with the general law of the land. But the former applies to military persons only; among these its jurisdiction comprehends all matters relating to the discipline of the army, to the cognizance of which the civil courts are not competent—as disobedience of orders, cowardice, &c.; and extends to such crimes as desertion, mutiny, and holding correspondence with the enemy. On the other hand, every citizen who is not engaged in the military profession is subject to the general laws of the land alone, and is free from all the restraints which, by the necessity of preserving discipline, are imposed on the soldier: he is his own master, he can dispose of his time at pleasure, and the peculiar regulations of the military service are, to him, as though they did not exist.

This distinction between the two classes of persons with respect to military law is clearly expressed in the 'Mutiny Act,' as it is called, which was first passed in the reign of William III. It is there stated that the subjects of this realm cannot be punished in any other manner than conformably to the common laws of the country. But an exception is immediately made in the case of military persons; and there follow several enactments for the purpose of bringing soldiers who shall mutiny, excite sedition, or desert from the service, to a more exemplary and speedy punishment than the usual forms of law will allow.

Immediately after the Norman conquest of this country the military law consisted in the obligation imposed on the vassals of the crown to follow the king to the field, under penalty of a pecuniary fine or the forfeiture of their land. But the first known record concerning the regulation of the army is believed to be that which was made in the reign of King John; and this relates chiefly to the purchase of provisions at the sales held for supplying the army with necessaries. The ordonnances of Richard II. and of

Henry V., and the statutes of Henry VIII., contain many useful rules for the government and discipline of the army. They prescribe obedience to the king and the commanders; they award punishments for gaming, theft, and other crimes; for raising false alarms in the camp, and for the seizure of religious persons. They also contain regulations concerning the disposal of prisoners taken in battle, and concerning the stakes, fascines, ladders, and other materials for military operations, with which the soldiers were to provide themselves. (*Grose*, vol. ii.)

The early kings of this country do not appear to have exercised, generally, a discretionary power over the army; for a statute of Edward I. states that the king had power to punish soldiers only according to the laws of the realm. The court of high constable and high marshal of England had for many years an exclusive jurisdiction in all military affairs, and this was sometimes extended over the civil courts. But the power of that court was restrained by a statute in the reign of Richard II. (1386), and it subsequently expired. From the time of Henry VII. till the reign of Charles I. the enactment of laws for the government of the army depended on the king alone.

The excesses which, during the last-mentioned reign, were committed by the undisciplined army which that ill-advised prince quartered on such of the people as had refused to lend money to the crown for raising them, led to the promulgation of a martial law, by which power was given to the magistrates to arrest and execute the persons guilty of murders, robberies, and other crimes, as in time of war. The *petition of right* abolished martial law for a time in this country, but it was subsequently restored by the parliament, and several ordinances of great severity were during the interregnum enacted respecting the maintenance of discipline. In the beginning of the reign of James II., after the rebellion of the Duke of Monmouth, several executions took place by martial law; and this may be said to have been the last occasion on which the law was exercised in Great Britain. At the time of the Revolution the present regular code was established for the government of the army; and this, under the name of the 'Mutiny Act,' has ever since been annually renewed by parliament.

(Grose, *Military Antiquities*; Tytler's *Essay on Military Law*, by Charles James; Samuel, *Historical Account of the British Army*; Major Adye, *Treatise on Military Law*; Major-General C. J. Napier, *Remarks on Military Law*. See also COURTS-MARTIAL.)

MARTIA'LIS, MARCUS VALE'RIUS, was a native of Bilbilis [BILBILIS], in Spain, where he was born on the Calends of March, about the year 40 A.D. Very few particulars of his life are ascertained, and even these are principally collected from his own writings. He came to Rome at an early age, and passed about thirty-five years of his life in that city. He left Rome probably about the commencement of Trajan's reign, and retired to his native town. The emperor Titus appears to have been his first imperial patron. Domitian, the successor of Titus, gave him the 'jus trium liberorum,' and conferred on him the dignity of tribune (*Epig.* ii. 91; iii. 95), for which and other favours the grateful poet made a most abundant return of flattery. Some critics have supposed that the author was married, and had a wife Marcella (xii., 21, 31); but the conclusion to be drawn from his writings is on the whole the other way. Martial was acquainted with most of his literary contemporaries, Juvenal, Quintilian, Pliny the younger, and others, as appears from his own writings (ii., 90; xii., 18, &c.).

There are extant of Martial fourteen books, entitled 'Epigrammata,' of which the thirteenth also bears the particular name of Xenia, and the fourteenth that of Apophoreta. A book called 'Spectaculorum Liber,' which is prefixed to the 'Epigrams,' contains a number of small poems on the shows of Titus and Domitian, and, as some critics suppose, may not be altogether the work of Martial. The whole collection contains above 1500 epigrams.

Many of the epigrams of Martial belong to that class of compositions which are now known by the name of epigrams, and may be considered as the prototype of that species of composition: they are short pieces, varying in length from two lines to four, six, or more, the point of which is generally contained in the last line. Like modern compositions of this kind, the thought is often forced and laboured, and the whole meaning sometimes obscure. Other of his compositions belong to that class more properly called epigrams [EPIGRAM], according to the original signification of the word, and are often characterized by great felicity of expression: they are on a great variety of subjects, and contain much matter that needs and requires comment. There is perhaps no Roman writer extant whose works, if well studied, would be so useful as Martial in illustrating the period in which he lived. Martial's description of his native Bilbilis and the river Salo (Xalon) which flows by it, and several other pieces, show a taste for a country life, and a poetic vein hardly inferior to that of Horace (i. 50, &c.). The twelfth book of his 'Epigrams' was published after his return to Bilbilis (xii. 3).

Many of the epigrams of Martial are as gross and obscene as thought and expression can make them; as to which it may be sufficient to remark that the manners of his age did not forbid the publication of obscene poetry, and that in this respect Martial was no worse than many of his contemporaries. In the Delphin edition the most obscene epigrams have been carefully selected and placed together at the end of the work, for reasons which, as there given, do not appear very satisfactory.

The editions and translations of Martial are very numerous. There are several English translations, the latest of which, so far as we know, is that by James Elphinstone, London, 1782.

MARTIGUES, LES, a town in France in the department of Bouches du Rhône, on the channel which forms the communication between the étang or lake of Martigues, or Berre, and the sea. It consists of three parts communicating with each other by bridges: the most antient part, called the Isle, is on an island in the mid channel; the other two, called Jonquières and Ferrières, are on the south-east and north-west banks respectively. The streets are generally well laid out and the houses neatly built. The banks of the channel are lined with quays. There are a spacious and regularly built town-hall and a handsome church. The population in 1831 was 5335 for the town, or 7379 for the whole commune; the inhabitants are engaged as seamen, or in the manufacture of hats, in ship-building, and in the fishery on the lake. They export oil, wine, salt, and a great quantity of fish. The fish of the Mediterranean resort periodically to the lake, where the greater part are taken by the fishermen.

MARTIN (Ornithology), the name for some of the Swallow tribe, as the *House Martin* (*Hirundo urbica*, Linn.), the *Bank* or *Sand Martin* (*Hirundo riparia*), and the *Black Martin* or *Swift*. [SWALLOWS.]

MARTIN I., a Tuscan by birth, succeeded Theodore I. in the see of Rome, A.D. 649. He held a council of Italian bishops in the Lateran church, in which the Monothelites were condemned. The emperor Constans II., who favoured the Monothelites, gave orders to the exarch of Ravenna to seize the person of the pope. Martin was taken to Constantinople, where a judicial inquiry was instituted against him for disobedience to the emperor, and he was banished to the Thracian Chersonesus, where he died in 655. He was succeeded by Eugenius I.

MARTIN II., called by some Marinus I., succeeded John VIII. in 882, and died in 884. He was succeeded by Adrian III.

MARTIN III., called by some Marinus II., a Roman by birth, succeeded Stephen VIII. in 942. He died in 946, and was succeeded by Agapitus II.

MARTIN IV., cardinal Simon de Brie, a native of France, succeeded Nicholas III. in the papal chair in 1281, through the influence of Charles of Anjou, king of Sicily and Naples. The Sicilian Vespers in 1282 having deprived Charles of Sicily, Martin excommunicated Peter of Aragon, whom the Sicilians had elected king, but his excommunication was of no more avail than the arms of the Angevins, for the Sicilians stood firm against both. Martin excommunicated the Byzantine emperor Michael, by which he widened the breach between the Greek and Latin churches. He died in 1285, and was succeeded by Honorius IV.

MARTIN V., Cardinal Otho Colonna, of an illustrious Roman family, was chosen by the council of Constance, after the deposition of John XXIII. and of the two antipopes Gregory and Benedict. Martin closed the council of Constance, in April, 1417, without its having effected the reforms in the church which were expected from it by Europe in general. Martin however promised to call together a new council for the purpose, which after much delay met first at Siena and afterwards at Basle in Switzer land, whither the pope sent his legate, cardinal Julian Cesarini, in 1431. But Martin died soon after, and was succeeded by Eugenius IV.

MARTIN-DE-RE', ST. [CHARENTE INFÉRIEURE.]

MARTIN, SAINT, one of the Lesser Antilles, lies to the south of Anguilla, from which island it is separated by a deep channel, about four miles wide in the narrowest part. Saint Martin is about 12 miles long and of a very irregular shape; its area is about 90 square miles. It contains no mountains, but a great number of rocky hills. The soil of the valleys and plains is sandy, and not very productive; there are no rivers or running streams on the island. The little rain which falls is collected into cisterns. The produce consists of sugar, cotton, and tobacco. The island also contains some valuable salt-ponds.

Saint Martin was originally settled by Spaniards, soon after the discovery of the West Indies by Columbus, but they abandoned the island in the middle of the seventeenth century. After this it was held jointly by the French and the Dutch, the former taking the northern and the latter the southern half, which is the most valuable, from its containing the salt-ponds. In March, 1801, the island was taken by the English, but at the peace of Paris was given up wholly to the Dutch, who have since retained possession of it. Philisburg, the town, is on the south-west side, in 18° 1′ N. lat. and 63° 7′ W. long.; it has a commodious harbour with from 8 to 10 fathoms water.

MARTINI, GIAMBATTISTA, well known throughout Europe under the title of the Padre Martini, was born at Bologna in 1706. Early in youth he entered the order of St. Francis, and, prompted by a spirit of inquiry and love of antiquity, soon set out on travels which he extended to Asia, on his return from which he seriously recommenced the study of music, under the celebrated Ant. Perti. In 1725 he became Maestro di Capella of the convent of his order, which office he retained till his death. 'He was,' says Dr. Burney, who knew him well, 'regarded during the last fifty years of his life as the most profound harmonist, and the best acquainted with the art and science of music, in Italy. All the great masters of his time were ambitious of becoming his disciples, and proud of his approbation.' He was also a composer, and produced much music for the church, which was formerly held in esteem. His sixty Canons in the unison, for 2, 3, and 4 voices, are still known, and admired for their smoothness and grace. But the reputation of the excellent and learned Father is built, and durably, on his Essay on Counterpoint, published, in two folio volumes, at Bologna, in 1774; and on his History of Music, in three volumes, quarto, the last of which appeared in 1781.

Martini's Essay (*Saggio fondamentale pratico di Contrappunto sopra il Canto-Fermo*) is divided into two parts. In the first is a compendium of the rules of counterpoint, explaining clearly, and well illustrating, the laws of harmony. This is followed by the application of the foregoing to *Canto-Fermo* [PLAIN-CHANT], and succeeded by upwards of sixty compositions by the great masters of the antient Italian school. The second part is wholly devoted to fugue and canon, and is extremely recondite, containing, however, too many musical enigmas and other matters which, happily, have no value in the present day: but compensation is made, for what now can only be considered as laborious trifling, by nearly fifty specimens of composition, in from two to eight parts, by several of the most distinguished of the old Italian masters.

The History (*Storia della Musica*) by Martini was intended to be most voluminous, it is to be presumed, for the third volume only reaches the time of Alexander the Great. What is completed exhibits vast erudition and astonishing research, but is grievously defective in plan; and though valuable as a work of reference, will now be read chiefly by the studious professor and the patient antiquary, who may derive from it much curious and useful information. The materials collected by the author for his purpose were of surprising extent; the number of volumes in his library amounted, we are told, to seventeen thousand, of which three hundred were manuscripts of great rarity; and a large part of all this he was enabled to purchase and obtain through the generosity and interest of Farinelli, the famous singer, whose numerous acts of liberality and benevolence proved that he was able to repress his resentment against mankind for having sanctioned the cruel practices under which he had suffered. Martini died in 1784.

MARTINI, GIUSEPPE SAN, a composer of distinguished merit, and a most celebrated performer on the oboe—an instrument which he may be said to have civilized—was a native of Milan, and arrived in England in 1723. He was soon engaged at all the public and private concerts, and in 1740 was taken into the service of the Prince of Wales, and received the appointment of music-master to the princesses. His Twelve Sonatas for two violins and violoncello were long in the highest favour with the public; but his best work is his Concertos for a full band, which display great invention, very elegant taste, and a thorough knowledge of his art. He died in 1750.

MARTINI, VINCENZO, commonly known as Martini of Madrid, was born at Valencia in Spain, about the year 1756. He was Maestro di Capella to the prince of Asturias, in 1785, and has always been thought one of the most agreeable composers of Italian operas. Among his works are *L'Arbore di Diana*, brought out at Vienna in 1787, and *La Cosa Rara*, produced about the same time, both of which have been everywhere popular, particularly the latter, which is well known on our English as well as on the Italian stages, Stephen Storace having introduced most of it in Cobb's opera, the *Siege of Belgrade*.

MARTINIQUE, or MARTINICO, one of the largest of the Caribbee Islands, is 10 leagues south-south-east of Dominica. The greatest length is 39 miles from north-west to south-east, and the mean breadth is about 16 miles; in form it is very irregular, and its surface is very uneven, being generally occupied by conical shaped hills. Three mountains of considerable height are visible on approaching the island in any direction; one of these, Mont Pelée, on the north-west side, is an exhausted volcano; the summits of the three are mostly covered with clouds. The island contains a great number of streams, and the coast, being indented by numerous bays and inlets, affords many good harbours. There are two principal towns, Saint Pierre and Port Royal, both on the west side of the island; the former is in 14° 44′ N. lat. and 61° 14′ W. long., and the latter in 14° 35′ N. lat. and 61° 7′ W. long. Port Royal, the residence of the governor, stands on the north side of a deep and well sheltered bay, protected by a fort which covers the whole surface of a peninsula and commands the town and harbour. During the war and while Martinique was in possession of the English, Port Royal was the general rendezvous and head-quarters of the fleet stationed in the West Indies. The Diamond Rock, which is about three leagues south-south-east from Port Royal bay, was taken possession of by the English between the breaking out of the war in 1803 and the capture of the island in 1809, and was commissioned and rated as a sloop of war in the British navy. Saint Pierre is an open roadstead, affording very indifferent shelter to shipping, but it is the principal place of trade in the island, and is said to be the handsomest town in the West Indies. It consists of three spacious streets parallel to the beach, and several transverse streets. Streams of water are conveyed through the principal streets, and impart a degree of freshness to the air most desirable in so warm a climate.

The population of the island in 1834 consisted of 35,766 whites and free coloured persons, and 79,233 slaves; together 114,999.

The staple production of the island is sugar, of which it yielded in 1834, 28,692 tons, besides 8748 tons of molasses and 385,609 gallons of rum. There were also grown about 600 tons of coffee, and small quantities of cotton, cocoa, and cloves. The total value of the imports in that year was 455,000*l*., and of the exports 647,000*l*. The number and tonnage of ships that arrived and sailed were—

	Vessels.	Tons.
Arrived—French ships . .	375	50,121
,, Foreign ships . .	440	tonnage not stated.
Sailed—French ships . .	371	48,063
,, Foreign ships .	444	tonnage not stated.

The foreign vessels were chiefly craft from the neighbouring English colonies; the rest were Americans.

Martinique was first settled by a party of about 100 men headed by a French planter, M. Desnambuc, from St. Christopher, in 1635. The island was at that time peopled by Caribs, but in the course of a very few years they were exterminated. It was taken in 1762 by the English, but was restored at the peace in the following year. In 1794 it was again taken by the English, and again restored to France at the peace of Amiens. It was once more captured by the English in 1810, and finally restored by the treaty of Paris in 1814, since which time it has remained under the dominion of France. At the beginning of the present year (1839) the island suffered the shock of an earthquake, which did considerable damage to the town of St. Pierre, and almost wholly destroyed Port Royal, in which town upwards of 500 persons were killed by the falling of the buildings, including nearly all the inmates of the principal hospital. The works and the negro villages of many of the sugar plantations were destroyed by the same shock.

MARTLET. [HERALDRY.]

MARTOS, IVAN PETROVITCH, director of the Academy of Fine Arts, St. Petersburg, was not only the most eminent sculptor Russia has yet produced (and she has given birth to a Prokophiev and a Kozlovsky), but one who would have ranked high in almost any age or country. The number of his works is very considerable, and among the more important are the following public monuments:—the bronze colossal group of the patriot Minin and Pozharsky, at Moscow; the monument to the emperor Alexander, at Taganrog; the statue of the duke of Richelieu, at Odessa; Potemkin's monument, at Cherson; and that erected in honour of Lomonosov, at Arkhangel. Martos has been styled the Canova of Russia; and while some have admitted that his works are inferior to those of the great Italian artist in point of refined elegance and high finish, they assert them to be free from that mannerism and over-studied gracefulness which were Canova's defects. It has been further admitted that they do not evince equal power of imagination with those of his countryman Kozlovsky, although on the other hand they stand the test of a critical scrutiny much better. Their characteristics are nobleness of conception, truth of expression, and freedom, without negligence, of execution. In the draping of his figures he was, if anything, superior to Canova, besides which he had a particular talent for bas-relief subjects. One of the most admired of these is that which adorns the monument of the grand-duchess Helena Paulovna, and which represents Hymen extinguishing a torch. Martos died April 17th, 1835, being upwards of eighty years of age.

MARTYN, HENRY, known as *The Missionary*, born 1781, died 1812. The short life of this amiable and zealous man may thus in brief be delineated. His birth was obscure. He was the son of a person who had been a labourer in the mines at Gwennap in Cornwall, but who was probably a person of talent and virtue, as he raised himself to the situation of clerk to a merchant at Truro, in which town Henry Martyn was born. He had his education in the grammar-school of Truro, and having acquired a considerable share of grammar learning, he tried for a scholarship in Corpus Christi College, Oxford; but failing in this, in 1797 he entered Saint John's College, Cambridge. Here he pursued his studies with such energy, that in 1801 he came out senior wrangler. During this period also his mind became directed with more than common earnestness to the truths of revelation. The death of his father is thought to have affected him at this period of his life so deeply as to have had no small share in turning his thoughts into the channel in which from this time they continued to flow; and not less the intimacy which at this time began with the Rev. Charles Simeon, the celebrated evangelical preacher in the university of Cambridge. He was chosen fellow of St. John's in March, 1802; but out of zeal in the cause of religion, he finally determined to devote himself to the work in which many of his countrymen had by that time begun to engage themselves, of propagating Christianity in nations which had not received it. There had been, it is true, a Society in England associated for the purpose of propagating the gospel in foreign parts, but a new impulse and a new energy were given to such operations by the establishment of Missionary Societies, supported by the Methodists, the Independent Dissenters, and by the Evangelical party in the church. Mr. Martyn was not content with supporting this object by his influence at home, but he proposed himself to the African and Eastern Missionary Society as a person willing to undertake the duties of a missionary in the East, and finally embarked for India in 1805.

It now became necessary that he should make himself ster of the languages of the countries which he was about sit; and with what success he studied them is evi-ed by the fact that he had the superintendence of the lations of the New Testament made under the instructions of the Missionary Society, both into Persian and Hindustanee. He made also some progress in an Arabic translation. In his capacity of missionary he traversed large tracts both of India and Persia. After above five years' labour in these countries, his health began to decline, and it soon became manifest that he would see his native shores no more. He did however make the attempt to return; but his strength wholly failing him, he was obliged to halt at Tokat, in Asia Minor, about 250 miles from Constantinople, where in a few days he died. The regrets in England which this event occasioned were great. Much was expected from him, and much would probably have been done by him in the cause to which he had devoted himself. As it was, he brought not a few both Hindus and Mohammedans to make profession of the Christian faith, and he caused the Scriptures to be extensively dispersed among a people who had not previously known them.

An interesting account of his life, compiled from various Journals left by him, was published by the Rev. John Sargent, 1819.

MARTYR, JUSTIN. [JUSTIN MARTYR.]

MARTYRS, MARTYROLOGY, from the Greek *Martur* or *Martus* (μάρτυρ or μάρτυς), *a witness*.

By the term *martyr* we now generally understand a person who suffers death rather than renounce his religious opinions; and those who have made a profession of their faith and thereby endured sufferings short of death are called *confessors*. These terms appear to have been used in the same sense by some of the early Christian writers; but others give the title of *martyr* to all who suffered tortures on account of their faith, and that of *confessor* to those who were only imprisoned for its avowal. Tertullian calls the latter 'martyres designati,' *martyrs elect*. The duty of enduring suffering, and even death, for the sake of religion was plainly taught by Christ and the apostles. (*Matt.*, x. 17-39; xvi. 25; *Rev.*, ii. 10, 11.) In the *Acts of the Apostles* we have several instances of the patience and even exultation of the first Christians under persecution; and in some passages martyrs are spoken of with peculiar honour. (*Acts*, xxii. 20; 2 *Tim.*, i. 8; *Rev.*, ii. 13; vi. 9-11; xvii. 6; xx. 4.) The annals of the early Christian church contain the histories of many martyrs, whose astonishing fortitude under the most cruel tortures was doubtless one great cause of the rapid diffusion of Christianity. Among the earliest and most valuable documents relating to this subject are the letter of the church at Smyrna, giving an account of the martyrdom of Polycarp (A.D. 167), and that of the churches at Lyon and Vienne (A.D. 177), concerning the martyrs who suffered in the same reign, namely, that of Marcus Aurelius Antoninus. (Eusebius, *Ecc. Hist.*, iv. 5; v. i.; and Lardner's *Works*, vol. vii., p. 150, edition of 1831.) We learn from these accounts that martyrs were highly honoured by the church, but we read nothing of that intercessory power nor of those extraordinary privileges which were ascribed to them in later ages. The degree of honour paid to them is expressed by the writers of the letter from Smyrna, where they state that the governor was induced to refuse their request to have the body of Polycarp delivered to them, 'lest they should leave him that was crucified, to worship this man; . . . . little considering that we can never forsake Christ, who has suffered for the salvation of all men. Him we worship as the Son of God. The martyrs we love as the disciples and imitators of the Lord.' But in less than a century the reverence felt towards martyrs became quite extravagant and superstitious. We learn from the writings of Cyprian, bishop of Carthage (A.D. 248), that the sufferings of martyrdom were held to purge away the stain of sin, so that the martyr was admitted at once into paradise without needing the fires of purgatory: martyrs were thought to expiate by their blood not only their own sins, but those of other men, and even of the church; and the fiery baptism of martyrdom was accounted of equal efficacy with the sacraments of Christ. The sense of pain was believed to be blunted or even removed by miraculous power. If they expired under their tortures, temples (called *martyrum confessiones* or *memoriæ*) were built over their graves, yearly festivals were instituted in their honour, their relics were held sacred and believed to have the power of working miracles, and their intercession with God was invoked as being peculiarly prevalent. If their sufferings fell short of death, they had ever after the highest authority in the church. But these honours appear sometimes to have had a bad effect on those to whom they was paid, for Cyprian complains strongly of the disgraceful conduct of some who had been confessors.

In proportion to the honour paid to martyrdom was the disgrace attached to those who found it. But here we observe a remarkable difference. In the earliest ages the Christians, acting upon Christ's command in *Matt.*, x. 23, did not think it disgraceful to avoid persecution by flight; but in later times the glory ascribed to martyrdom induced men to throw themselves in its way. Tertullian wrote a book against all flight in persecution; and Cyprian himself, when he retired from Carthage during a persecution, did not attempt to defend his conduct by general arguments, but pleaded an express revelation from God as his excuse. In a word, the martyrs of this age seem to have had more ambition and less steadfastness than those of earlier times.

The earliest accounts of Christian martyrdoms, for instance, that of Stephen in the *Acts* (vii.), are related with the utmost simplicity; but it was not long before the narratives of the deaths of martyrs were adorned with accounts of miracles, which, to say the least, are difficult to believe. This fashion had commenced even in the second century, for we find examples of it in the letter already mentioned, which relates the death of Polycarp. On these miracles Middleton remarks, 'These deaths of the primitive martyrs seldom failed of being accompanied by miracles, which, as we find them related in the old Martyrologies, were generally copied from each other; concerning sweet smells issuing from their bodies, and their wonderful resistance to all kinds of torture; and the miraculous cures of their wounds and bruises, so as to tire their tormentors by the difficulty of destroying them, which yet, after a vain profusion of miracles, was always effected at the last.' (*Free Enquiry*, p. 126, note.)

It is very difficult to ascertain the number of martyrs who suffered in the early persecutions. Some writers have made it enormous, others quite insignificant. Among the latter is Dodwell, who has written an elaborate dissertation on the subject. (*Dissertationes Cyprianicæ*, Diss. xi.) The expressions of Eusebius and other ecclesiastical writers would lead us to infer that the number of martyrs was considerable, but probably it has been much overrated.

Middleton has shown that many of the accounts in the *Martyrologies* are fabulous. He mentions, in his 'Letter from Rome,' some curious instances in which persons who never existed, heathen deities with their names slightly or not at all changed, and even inanimate objects, have been canonized as saints and martyrs.

That department of ecclesiastical history which relates to the acts and deaths of martyrs is termed *martyrology*; and a work embracing one or more such narratives is called a *martyrology*. As examples of this description of works we may mention the 'Martyrology' of Eusebius, which was translated into Latin by Jerome, and was celebrated in the early church, but is lost; that ascribed to the venerable Bede, but the genuineness of which is very doubtful; and the 'Acts and Monuments' of Fox, which is an elaborate and valuable record of the sufferings of the English reformers.

Much interesting information on this subject may be found in Ruinart's *Acta Martyrum*, Dodwell's *Dissertationes Cyprianicæ*, x., xi., xii., xiii., and Dr. Conyers Middleton's *Free Enquiry into the Miraculous Powers supposed to have subsisted in the Christian Church*.

MARVEJOLS. [Lozère.]

MARVELL, ANDREW, was born on the 15th of November, 1620, at Kingston-upon-Hull, where his father was master of the grammar-school and lecturer of Trinity church. At the age of fifteen he was sent to Trinity College, Cambridge. All that is known of Marvell's career through the university is what may be gathered, and that is not much certainly, from the following entry in the Conclusion Book of his college, under date September 24th, 1641:—'It is agreed by the master and eight seniors that Mr. Carter, Dominus Wakefield, Dominus Marvell, Dominus Waterhouse, and Dominus Maye, in regard that some of them are reported to be married, and the others looke not after their dayes nor acts, shall receive no more benefit of the colledge and shall be out of their places, unless they shew just cause to the colledge for the contrary in three monthes.'

For the ten following years there is little information respecting Marvell, though some notice of his occupations during that time may be gathered from the following passage of a letter from Milton to Bradshaw, dated February 21, 1652:—'He (Marvell) hath spent four years abroad in Holland, France, Italy, and Spain, to very good purpose, as I believe, and the gaining of those four languages; besides he is a scholar, and well read in the Latin and Greek authors, and no doubt of an approved conversation, for he comes now lately out of the house of the Lord Fairfax, who was general, where he was intrusted to give some instructions in the languages to the lady his daughter.'

In 1660 Andrew Marvell commenced his parliamentary career. We may judge of the manner in which he acted in that course from an anecdote which has been often related, varying somewhat as to details, though the same in the main circumstances.

The following version of it is extracted from a pamphlet printed in Ireland about 1754; but we think it has too melodramatic an air to be strictly accurate. 'The borough of Hull, in the reign of Charles II., chose Andrew Marvell, a young gentleman of little or no fortune, and maintained him in London for the service of the public. His understanding, integrity, and spirit were dreadful to the then infamous administration. Persuaded that he would be theirs for properly asking, they sent his old schoolfellow the lord-treasurer Danby, to renew acquaintance with him in his garret. At parting the lord-treasurer, out of pure affection, slipped into his hand an order upon the treasury for 1000*l*., and then went to his chariot. Marvell, looking at the paper, calls after the treasurer, 'My lord, I request another moment.' They went up again to the garret, and Jack, the servant boy, was called. 'Jack, child, what had I for dinner yesterday?' 'Don't you remember, sir? You had the little shoulder of mutton that you ordered me to bring from a woman in the market.' 'Very right, child. What have I for dinner to-day?' 'Don't you know, sir, that you bid me lay by the blade-bone to broil?' 'Tis so; very right, child; go away.' 'My lord, do you hear that? Andrew Marvell's dinner is provided; there's your piece of paper. I want it not. I know the sort of kindness you intended. I live here to serve my constituents: the ministry may seek men for their purpose; I am not one.'

Marvell was twice elected member for Hull in 1660. In April, 1661, he thus writes to his constituents:—'I perceive you have again (as if it were grown a thing of course) made choice of me, now the third time, to serve you in parliament; which as I cannot attribute to any thing but your constancy, so I find myself, as in gratitude obliged, with no less constancy and vigour I shall continue to execute your commands and study your service.' Marvell really had cause to be grateful for their constancy. They were undeviating in their support of a man who had neither wealth, nor power, nor rank, nor even brilliant reputation to strike the vulgar eye and dazzle the vulgar imagination; and who had in fact nothing to recommend him but his unostentatious adherence to what he considered to be the line of his duty.

Throughout the whole of Marvell's parliamentary career the electors are no less deserving of praise than the elected. In the first parliament in which Marvell served, he and his colleague, Mr. Ramsden, used to write jointly. But afterwards Colonel Gilby was elected in the room of Mr. Ramsden, and then, in consequence of some misunderstanding between him and Marvell, the latter wrote singly to his constituents. He thus alludes to the difference between them:—'Though perhaps we may differ in our advice concerning the way of proceeding, yet we have the same good ends in general; and by this unlucky falling out we shall be provoked to a greater emulation of serving you. I must beg you to pardon me for writing singly to you, for if I wanted my right hand yet I would scribble to you with my left rather than neglect your business.'

A gap occurs in Marvell's correspondence after June, 1661. He appears to have been in Holland for a considerable time. Lord Bellasis, then high-steward of Hull, having requested the corporation to proceed to the election of a new member, they wrote to Marvell, who immediately returned to England and resumed his seat in the house.

About three months after his return Marvell again left England as secretary to Lord Carlisle, who was appointed ambassador extraordinary to Russia, Sweden, and Denmark. Marvell's acceptance of this appointment seems a little at variance with his alleged invariable refusal to accept any mark of royal favour.

Marvell was absent on this embassy nearly two years.

On his return he began to correspond with his constituents almost every post.

The following passages are characteristic both of the man and the times:—

'*Nov.* 14, 1667.—Really the business of the House hath been of late so earnest daily and so busy, that I have not had the time and scarce vigour left me by night to write to you; and to-day, because I would not omit any longer, I lose my dinner to make sure of this letter.' *Letter to Mayor and Aldermen of Hull.*

'*April* 14, 1670.—The king about ten o'clock took boat with Lauderdale only, and two ordinary attendants, and rowed awhile as towards the bridge; but soon turned back to the Parlt. Stairs, and so went up into the House of Lords and took his seat. Almost all of them were amazed, but all seemed so, and the duke of York especially was very much surprised. He told them it was a privilege he claimed from his ancestors, to be present at their deliberations. After three or four days' continuance, the lords were very well used to the king's presence, and sent the lord-steward and lord-chamberlain to him to enquire when they might wait as an House on him, to render their humble thanks for the honour he did them. The hour was appointed them, and they thanked him, and he took it well. The king has ever since continued his session among them, and says, "it is better than going to a play."' *Letter to William Ramsden, Esq.*

The following presents a curious picture of the government of Charles II.:—

'The king having, upon pretence of the great preparations of his neighbours, demanded 300,000*l.* for his navy (though, in conclusion, he hath not sent out any), that the parliament should pay his debts, which the ministers would never particularize to the House of Commons, our house gave several bills. You see how far things were stretched beyond reason, there being no satisfaction how those debts were contracted; and all men foreseeing that what was given would not be applied to discharge the debts, which I hear are at this day risen to four millions, but diverted as formerly. Nevertheless, such was the number of the constant courtiers, increased by the apostate patriots, who were bought off for that term, some at six, others at ten, one at fifteen thousand pounds, in money; besides what offices, lands, and reversions to others, that it is a mercy they gave not away the whole land and liberty of England. The duke of Buckingham is again 140,000*l.* in debt, and, by this prorogation, his creditors have time to tear all his lands in pieces. The House of Commons has run almost to the end of their line, and are grown extremely chargeable to the king and odious to the people. They have signed and sealed 10,000*l.* a year more to the duchess of Cleveland, who has likewise near 10,000*l.* a year out of the new farm of the country excise of beer and ale; 5000*l.* a year out of the post-office; and, they say, the reversion of all the king's leases; the reversion of all places in the custom-house, the green wax, and, indeed, what not. All promotions, spiritual and temporal, pass under her cognizance.'

In 1672 Marvell engaged in a controversy with Dr. Samuel Parker (afterwards nominated bishop of Oxford by James II.). The following are a few of Parker's opinions, published in 1670, in a book entitled 'Ecclesiastical Polity.' 'It is better to submit to the unreasonable impositions of Nero and Caligula than to hazard the dissolution of the state.' 'Princes may with less hazard give liberty to men's vices than to their consciences.' Of the different sects then subsisting he held 'that tenderness and indulgence to such men were to nourish vipers in our bowels, and the most sottish neglect of our own quiet and security.'

Marvell's various publications were mostly of a temporary interest. Mr. Dove gives the following account of the close of his career. 'Marvell had now rendered himself so obnoxious to the usual friends of a corrupt court, and to the heir presumptive, James, duke of York, that he was beset on all sides by powerful enemies, who even proceeded so far as to menace his life. Hence he was obliged to use great caution, to appear seldom in public, and frequently to conceal the place of his abode; but all his care proved ineffectual to preserve him from their vengeance, for he died on the 16th of August, 1678, aged fifty-eight years, not without strong suspicions (as his constitution was entire and vigorous) of having suffered under the effect of poison.' (*Life of Andrew Marvell*, p. 65, London, 1832.)

Marvell's powers as a poet were not sufficient to ensure him lasting fame. Few or none of his poetical compositions, any more than his prose, obtained a lasting popularity. Many of his verses, particularly the satirical, are defaced by the coarseness of his time, from which his contemporary, Milton, is so remarkably free. Others display a degree of feeling and a perception of the beauties of nature, expressed with a harmony of versification and felicity of language which not unfrequently recall the 'L'Allegro' and 'Il Penseroso' of Milton. But Marvell's verse did not possess sufficient vitality to secure its continued existence. He says of it himself, with a sort of prophetic truth, in his lines to 'His Coy Mistress,'—

> 'But at my back I always hear
> Time's winged chariot hurrying near;
> And yonder all before us lie
> Deserts of vast eternity.
> Thy beauty shall no more be found,
> Nor in thy marble vault shall sound
> My echoing song.'

Upon the whole Andrew Marvell's claim to be honourably remembered is founded rather on his moral than his intellectual qualities. His intellectual merits are those of a wit and satirist; and though in these departments considerably above mediocrity, and even famous in his day, he could scarcely have hoped for a different fate from that of other wits and satirists who are now forgotten. But the degree in which Andrew Marvell possessed that very rare quality, political integrity, gives him a claim to the remembrance and even the reverence of after-ages, still greater than is due to him as the friend and associate of Milton.

(Marvell's Works, by Captain Edward Thompson, with his *Life*, London, 1776.)

MARWAR, a district or division of the province of Ajmeer, lying between 24° 35′ and 27° 45′ N. lat., and between 70° 25′ and 75° 15′ E. long. Its greatest length from north-east to south-west is 310 miles, and its mean breadth is about 120 miles. The surface of the district is irregular and mountainous, rising towards the south; some of the mountains in that quarter indicate by the barometer an elevation of 5000 feet above the level of the sea: European fruits and shrubs are produced on their summits. The country contains many hill forts, and is for the most part subject to the rajah of Joudpore. The population is partly Mohammedan and partly Hindu; but there are, besides these sects, many tribes of uncivilized people, who, by their predatory habits, are frequently troublesome to their more quiet neighbours. The failure of the annual fall of rain in 1811, together with the desolation occasioned by clouds of locusts, produced a dreadful famine throughout the district, and drove great numbers of the inhabitants into the province of Gujerat, which, in the following year, also experienced a failure of rain, and the people died by thousands in a state of the greatest misery, so that it is said scarcely one in a hundred ever returned to his native province. Marwar contains few towns of any size. Nagore, in [illegible] 8′ N. lat. and 73° 33′ E. long., stands upon barren sandy hills, with scarcely any vegetation within a mile of its walls, and it is badly supplied with water. The only other town requiring notice is Joudpore, the capital and the residence of the rajah, in 26° 18′ N. lat. and 73° 5′ E. long. The country has been so little visited by Europeans, that our knowledge concerning it is very scanty. The castle palace of Joudpore is said to be a large and very magnificent building. In 1818, when part of his territory was in the occupation of the sovereign of Jeypore, the rajah of Joudpore made an arrangement with the English government, under which, in return for our protection, he bound himself to the payment of an annual tribute of 10,800*l.*, and engaged to furnish a contingent of 1500 cavalry. The entire revenue of the district is estimated at 50 lacs of rupees (500,000*l.*), but usually falls far short of that sum.

MARY I., Queen of England, was the daughter of Henry VIII., by his first wife Catherine of Aragon, and was born at Greenwich, on the 18th (Burnet says 19th) of February, 1516. She was the only one of several children borne by her mother that lived; and on this account, according to Burnet, and because her father was then 'out of hope of more children,' he in 1518 'declared his daughter princess of Wales, and sent her to Ludlow to hold her court there, and projected divers matches for her.' It was first settled that she should be married to the dauphin by a treaty with the king of France, dated 9th November, 1518, which however was soon after broken. Then it was arranged, in June, 1522, that her hand should be given to the emperor

Charles V. On Charles declining to fulfil this bargain, some overtures of a Scottish marriage followed in September, 1526. Finally, in April, 1527, it was agreed that the princess should be given in marriage either to the French king Francis, or to his second son, the duke of Orleans; but before it was determined whether she should be married to the father or the son, the affair of her mother's divorce, implying her own illegitimacy, came to be agitated, and stopped all match-making for some years.

Mary was brought up from her infancy in a strong attachment to the ancient religion, under the care of her mother, and Margaret, countess of Salisbury, the effect of whose instructions was not impaired by the subsequent lessons of the learned Ludovicus Vives, who, though somewhat inclined to the reformed opinions, was appointed by Henry to be her Latin tutor. After her mother's divorce, Mary was deprived of her title of princess of Wales, which was transferred to the Princess Elizabeth soon after she came into the world; and during all the time that Anne Boleyn lived, Mary, who clung to her mother's cause and her own, remained in a state of estrangement from her father. In the mean time, according to Lord Herbert, negotiations for disposing of her in marriage were twice entered into by her near relation the emperor, without her father's consent having been asked; in 1533 he offered her to James V. of Scotland, and in 1535 to her old suitor the dauphin. But immediately after the execution of Queen Anne in 1536, a reconcilement took place between Henry and his eldest daughter, who, with great reluctance, was now prevailed upon to make a formal acknowledgment both of Henry's ecclesiastical supremacy—utterly refusing 'the bishop of Rome's pretended authority, power, and jurisdiction within this realm heretofore usurped'—and of the nullity of the marriage of her father and mother, which she declared was 'by God's law and man's law incestuous and unlawful.' (See the 'Confession of me, the Lady Mary,' as printed by Burnet, 'Hist. Ref.' from the original, 'all written with her own hand.') By the new act of succession however, passed this year, she was again, as well as her sister Elizabeth, declared illegitimate, and for ever excluded from claiming the inheritance of the crown as the king's lawful heir by lineal descent. While she was thus circumstanced, 'excluded,' as Lord Herbert expresses it, 'by act of parliament from all claim to the succession except such as the king shall give her' by the powers reserved to him of nominating his own successor after failure of the issue of Queen Jane, or of any other queen whom he might afterwards marry, she was in 1539 offered to Don Louis, prince of Portugal, and the next year to William, son of the duke of Cleves. Meanwhile continuing to yield an outward conformity in all her father's capricious movements in the matter of religion, she so far succeeded in regaining his favour, that in the new act of succession, passed in 1544, the inheritance to the crown was expressly secured to her next after her brother Edward and his heirs, and any issue the king might have by his then wife Catherine Parr.

Mary's compliance with the innovations in religion in her father's time had been dictated merely by fear or self-interest; and when, after the accession of her brother, his ministers proceeded to place the whole doctrine, as well as discipline, of the national church upon a new foundation, she openly refused to go along with them; nor could all their persuasions and threats, aided by those of her brother himself, move her from her ground. Full details of the various attempts that were made to prevail upon her may be found in Burnet's 'History,' and in King Edward's 'Journal.' Mention is made in the latter, under date of April, 1550, of a demand for the hand of the Lady Mary by the duke of Brunswick, who was informed by the council that 'there was talk for her marriage with the infant of Portugal, which being determined, he should have answer.' About the same time it is noted that 'whereas the emperor's ambassador desired leave, by letters patents, that my Lady Mary might have mass, it was denied him.' On the 18th of March of the following year, the king writes: "'The Lady Mary, my sister, came to me at Westminster, where, after salutations, she was called, with my council, into a chamber, where was declared how long I had suffered her mass, in hope of her reconciliation, and how now being no hope, which I perceived by her letters, except I saw some short amendment, I could not bear it. She answered, that her soul was God's, and her faith she would not change, nor dissemble her opinion with contrary doings. It was said, I constrained not her faith, but willed her not as a king to rule, but as a subject to obey; and that her example might breed too much inconvenience.' In fact throughout this reign the princess Mary was the centre of the intrigues of the Catholic party, and the hope of her succession their main strength and support. In the summer of that same year a project was entered into by her friends at home and abroad for removing her from England, where her faith at least, if not her person, was probably supposed to be in some danger. On the 9th of August her brother writes: 'Certain pensions were proposed to me that there should be no conveyance over sea of the Lady Mary secretly done. Also appointed that the lord chancellor, lord chamberlain, the vice-chamberlain, and the secretary Petre should see by all means they could whether she used the mass; and if she did, that the laws should be executed on her chaplains.'

Mary's firm adherence to the Roman faith finally induced Edward, under the interested advice of his minister Northumberland, to attempt at the close of his life to exclude her from the succession, and to make over the crown by will to the Lady Jane Grey, an act which was certainly without any shadow of legal force. [EDWARD VI.] Although Lady Jane however was actually proclaimed, scarcely any resistance was made to the accession of Mary, the commencement of whose reign accordingly is dated from the 6th of July, 1553, the day of her brother's death. [GREY, LADY JANE.]

Mary was scarcely seated on the throne when she proceeded to re-establish the ancient religion. In the course of the month of August, Bonner, Gardiner, and three other bishops, who had been deposed for nonconformity in the late reign, were restored to their sees, and the mass began again to be celebrated in many churches. In the following month archbishop Cranmer and bishop Latimer were committed to the Tower; and in November the parliament passed an act repealing all the acts, nine in number, relating to religion, that had been passed in the late reign, and replacing the church in the same position in which it had stood at the death of Henry VIII. These measures, and the other indications given by the court of a determination to be completely reconciled with Rome, were followed by the insurrection, commonly known as that of Sir Thomas Wyatt, its principal leader, which broke out in the end of January, 1554, but was in a few days effectually put down; its suppression being signalised by the executions of the unfortunate Lady Jane Grey and her husband the Lord Guildford Dudley, of her father the duke of Suffolk, and finally, of Wyatt himself.

On the 25th of July, Mary was married in the cathedral church of Winchester to the prince of Spain, afterwards Philip II., the son of the emperor Charles V.; and the reunion with Rome was speedily completed by a parliament which assembled in the beginning of November, and which passed acts repealing the attainder of cardinal Pole, who immediately after arrived in England with the dignity of papal legate, restoring the authority of the pope, repealing all laws made against the see of Rome since the 20th of Henry VIII., reviving the ancient statutes against heresy, and in short re-establishing the whole national system of religious policy as it had existed previous to the first innovations made by Henry VIII. By one of the acts of this session of parliament also Philip was authorised to take the title of King of England during the queen's life. All these acts appear to have been passed with scarcely any debate or opposition in either house, except occasionally upon mere points of detail and form.

The remainder of the history of the reign of Mary is occupied chiefly with the sanguinary persecutions of the adherents to the reformed doctrines. The Protestant writers reckon that about two hundred and eighty victims perished at the stake, from the 4th of February, 1555, on which day John Rogers was burnt at Smithfield, to the 10th of November, 1558, when the last *auto-da-fé* of the reign took place by the execution in the same manner of three men and two women at Colchester. Dr. Lingard admits that after expunging from the Protestant lists 'the names of all who were condemned as felons or traitors, or who died peaceably in their beds, or who survived the publication of their martyrdom, or who would for their heterodoxy have been sent to the stake by the reformed prelates themselves, had they been in possession of the power,' and making every other reasonable allowance, it will still be found that in the space of four years almost two hundred persons perished in the flames for religious opinion.' Among the most distinguished sufferers were Hooper bishop of Gloucester, Ferrar of St. David's, Latimer of Worcester, Ridley of London, and Cranmer archbishop of Canterbury. Gardiner, bishop of Winchester and lord chancellor, was Mary's chief minister till his death in November, 1555, after which the direction of affairs fell mostly into the hands of cardinal Pole, who after Cranmer's deposition was made archbishop of Canterbury; but the notorious Bonner, Ridley's successor in the see of London, has the credit of having been the principal instigator of these atrocities, which, it may be remarked, so far from contributing to put down the reformed doctrines, appear to have had a greater effect in disgusting the nation with the restored church than all other causes together.

At the same time that the new opinions in religion were thus attempted to be extinguished by committing the bodies of those who believed in them to the flames, the queen gave a further proof of the sincerity of her own faith by restoring to the church the tenths and first-fruits, with all the rectories, glebe-lands, and tithes that had been annexed to the crown in the times of her father and brother. She also re established several of the old religious houses, and endowed them as liberally as her means enabled her.

Tired both of the country and of his wife, Philip left England, in the beginning of September, 1555, and continued absent for about a year and a half. The bond however by which this marriage attached the English court to Spain and the Empire remained the same as ever; and when, after a short cessation of hostilities, war recommenced in the spring of 1557 between Spain and France, Mary was prevailed upon to join the former against the latter power. The principal consequence of this step, in so far as this country was concerned, was the loss of the only remaining English continental possession, the town and territory of Calais, which surrendered to the duke of Guise, in January, 1558, after a siege of a few days. This event, which was regarded as a national disgrace worse than any mere loss, excited the bitterest feelings of dissatisfaction with the policy of the court; and Mary herself is said never to have recovered from the blow. Some ineffectual efforts were made to retaliate upon France by force of arms; but at last negotiations for a peace between the three belligerent powers were opened at Cambray, in the midst of which queen Mary died, worn out with bodily and mental suffering, on the 17th of November, 1558, in the forty-third year of her age and the sixth of her reign. She is affirmed to have said on her deathbed, that if her breast should be opened after her decease, Calais would be found to be written on her heart. Mary left no issue, and was succeeded on the throne by her half-sister Elizabeth. [ELIZABETH.]

MARY STUART, queen of Scotland, was born on the 7th of December, 1542. She was the third child of king James V. of Scotland, by his wife Mary of Lorraine, daughter of the duke of Guise, who had previously borne her husband two sons, both of whom died in infancy. A report prevailed that Mary too was not likely to live; but being unswaddled by her nurse at the desire of her anxious mother, in presence of the English ambassador, the latter wrote to his court that she was as goodly a child as he had seen of her age. At the time of her birth her father lay sick in the palace of Falkland; and in the course of a few days after he expired, at the early age of thirty, his death being hastened by distress of mind occasioned by the defeats which his nobles had sustained at Fala and Solway Moss. James was naturally a person of considerable energy and vigour both of mind and body, but previous to his death he fell into a state of listlessness and despondency, and after his decease it was found that he had made no provision for the care of the infant princess, or for the administration of the government. The ambitious Beatoun seized this opportunity, and producing a testament which he pretended was that of the late king, immediately assumed the office and title of regent. The fraud was soon discovered; but by the haste and imprudence of the regent Arran and Henry VIII. of England, who wished a marriage agreed to between his son and the young queen, Beatoun regained his influence in the country; and on the 9th of September, 1543, Mary was crowned by the archbishop, who was also immediately afterwards appointed lord high chancellor of the kingdom. He had even the address to win over the regent Arran to his views, both political and religious; and thus the French or Roman Catholic party obtained the ascendancy. The first two years of Mary's life were spent at Linlithgow, in the royal palace of which she was born; she was then removed to Stirling castle; and when the disputes of parties in the country rendered this a somewhat dangerous residence, she was carried to Inchmahome, a sequestered island in the lake of Monteith, where she remained about two years. In the meantime a treaty of marriage had been concluded between her and the dauphin Francis; and in terms of the treaty it was resolved she should be sent into France to be educated at the French court, until the nuptials could be solemnized. Accordingly in the fifth year of her age she was taken to Dumbarton, where she was put on board the French fleet; and setting sail towards the end of July, 1548, she was, after a tempestuous voyage, landed on the 14th of August at Brest, whence she proceeded by easy stages to the palace at St. Germaine-en-Laye. At every town in her progress she was received with all the honours due to her royal rank, and as a mark of respect and joy the prisons were thrown open and the prisoners set free.

Soon after her arrival at her destination Mary was placed with the French king's own daughters in one of the first convents of the kingdom, where she made such rapid progress in the acquisition of the literature and accomplishments of the age, that when visiting her in the end of the year 1550, her mother, Mary of Guise, with her Scottish attendants, burst into tears of joy. She did not however remain long in this situation. Perceiving the bent of her mind to the society and occupations of a nunnery, which did not accord with the ambitious projects entertained by her uncles of Lorraine, they soon brought her to the court, which, as Robertson observes, was one of the politest but most corrupt in Europe. Here Mary became the envy of her sex, surpassing the most accomplished in the elegance and fluency of her language, the grace and liveliness of her movements, and the charm of her whole manner and behaviour. The youthful Francis, to whom she was betrothed, and was soon to be united in wedlock, was about her own age, and they had been playmates from early years: there appears also to have grown up a mutual affection between them; but the dauphin had little of her vivacity, and was altogether considerably her inferior both in mental endowments and personal appearance. The marriage, which took place on the 24th of April, 1558, was celebrated with great pomp; and when the dauphin, taking a ring from his finger, presented it to the cardinal Bourbon, archbishop of Rouen, who, pronouncing the benediction, placed it on the finger of the lovely and youthful bride, the vaulted roof of the cathedral rung with the shouts and congratulations of the assembled multitude.

The solemnities being over, the married pair retired to one of their princely retreats for the summer; but that season was hardly gone when, a vacancy having occurred on the throne of England by the death of Queen Mary, claims were put forth on behalf of the queen of Scots through her grandmother, who was eldest daughter of King Henry VII of England; and notwithstanding Elizabeth had ascended the throne, and was, like her sister Mary (both daughters of King Henry VIII.), queen both *de facto* and by the declaration of the parliament of England, yet this claim for the Scottish princess was made and continued to be urged with great pertinacity by her ambitious uncles the princes of Lorraine. On every occasion on which the dauphin and dauphiness appeared in public, they were ostentatiously greeted as the king and queen of England: the English arms were engraved upon their plate, embroidered on their banners, and painted on their furniture; and Mary's own favourite device at the time was, the two crowns of France and Scotland, with the motto *Aliamque moratur*, meaning that of England. Henri II. died in July, 1559, and in September of the same year Francis was solemnly crowned at Rheims. Mary was now at the height of her splendour; it was doomed however to be only of short continuance. In June, 1560, her mother died; and in December of the same year, her husband, who had been wasting away for some months, expired. By this latter event, Catherine de' Medici rose again into power in the French court, and Mary, who did not relish being second where she had been the first, immediately determined on quitting France and returning to her native country. The queen of England however interposed; and because Mary would not abandon all claim to the English throne, refused to grant her a free passage, being moved to [illegible] piece of discourtesy not less perhaps by envy than by jealousy. Mary notwithstanding resolved to go, and at length, after repeated delays, still lingering on the soil where fortune had smiled upon her, she reached Calais. Here she bade adieu to her attendants, and sailed for Scotland; but as long as the French coast remained in view, she continued involuntarily to exclaim, 'Farewell, France! Farewell, beloved country!' She landed at Leith on the 19th August, 1561, in the 19th year of her age, and after an absence from Scotland of nearly 13 years. She was now, in the language of Robertson, 'a stranger to her subjects, without experience, without allies, and almost without a friend.'

A great change had taken place in Scotland since Mary was last in the country. The Roman Catholic religion was then supreme; and under the direction of cardinal Beatoun the Romish clergy displayed a fierceness of intolerance which seemed to aim at nothing short of the utter extirpation of every seed of dissent and reform. The same causes however which gave strength to the ecclesiastics gave strength also, though more slowly, to the great body of the people; and at length, after the repeated losses of Floddon and Fala, and Solway Moss and Pinkey,—which, by the fall of nearly the whole lay nobility and leading men of the kingdom, brought all classes within the influence of public events,—the energies, physical and mental, of the entire nation were drawn out, and under the guidance of the reformer Knox expended themselves with the fury of awakened indignation upon the whole fabric of the antient religion. The work of destruction was just completed, and the Presbyterian government established on the ruins of the Roman Catholic, when Mary returned to her native land. She knew little of all this, and had been taught in France to shrink at the avowal of Protestant opinions: her habits and sentiments were therefore utterly at variance with those of her subjects; and, nurtured in the lap of ease, she was wholly unprepared for the shock which was inevitably to result from her being thrown among them.

Accordingly the very first Sunday after her arrival she commanded a solemn mass to be celebrated in the chapel of the palace; and, as might have been expected, an uproar ensued, the servants of the chapel were insulted and abused, and had not some of the lay nobility of the Protestant party interposed, the riot might have become general. The next Sunday Knox had a thundering sermon against idolatry, and in his discourse he took occasion to say that a single mass was, in his estimation, more to be feared than ten thousand armed men. Upon this, Mary sent for the reformer, desiring to have an interview with him. The interview took place, as well as one or two subsequent ones from a like cause; but the only result was to exhibit the parties more plainly at variance with each other. In one of these fruitless conferences the young queen was bathed in tears before his stern rebukes. Her youth however, her beauty and accomplishments, and her affability, interested many in her favour; and as she had from the first continued the government in the hands of the Protestants, the general peace of the country remained unbroken.

A remarkable proof of the popular favour which she had won, appeared in the circumstances attending her marriage with Darnley. Various proposals had been made to her from different quarters; but at length she gave up all thoughts of a foreign alliance, and her affections became fixed on her cousin Henry Stuart, lord Darnley, the youthful heir of the noble house of Lennox, to whom she was united on Sunday, 29th July, 1565, the ceremony of marriage being performed in the chapel of Holyrood-house, according to the rites of the Romish church. Whether the queen had any right to choose a husband without consent of parliament, was in that age, as Robertson observes, a matter of some dispute; but that she had no right to confer upon him, by her private authority, the title and dignity of king, or by a simple proclamation invest him with the character of a sovereign, was beyond all doubt: yet so entirely did she possess the favourable regard of the nation, that notwithstanding the clamours of the malecontents, her conduct in this respect produced no symptom of general dissatisfaction. The queen's marriage was particularly obnoxious to Queen Elizabeth, whose jealous eye had never been withdrawn from her rival. Knox also did not look favourably on it. Nevertheless the current of popular opinion ran decidedly in Mary's favour, and it was even remarked that the prosperous situation of her affairs began to work some change in favour of her religion.

This popularity however was the result of adventitious circumstances only. There existed no real sympathy or opinion between Mary and the great body of her people; and whatever led to the manifestation of her religious sentiments dissolved in the same degree the fascination which her other qualities had created. It is in this way we may account for the assistance given to Darnley in the assassination of Rizzio—an attendant on Mary, who seems to have come in place of Chatelard. The latter was a French poet who sailed in Mary's retinue when she came over from the Continent; and having gained the queen's attention by his poetical effusions, he proceeded, in the indulgence of a foolish attachment for her, to a boldness and audacity of behaviour which demanded at last the interposition of the law, and he was condemned and executed. Rizzio, a Piedmontese by birth, came to Edinburgh in the train of the ambassador from Savoy, a year or so before Chatelard's execution. He was skilled in music, had a polished and ready wit, and, like Chatelard, wrote with ease in French and Italian. His first employment at court was in his character of a musician; but Mary soon advanced him to be her French secretary; and in this situation he was conceived to possess an influence over the queen which was equally hateful to Darnley and the Reformers, though on very different grounds. Both therefore concurred in his destruction, and he was assassinated accordingly. Darnley afterwards disclaimed all concern in the conspiracy; but it was plain the queen did not believe and could not forgive him; and having but few qualities to secure her regard, her growing contempt of him terminated in disgust. In the mean time the well-known earl of Bothwell was rapidly advancing in the queen's favour, and at length no business was concluded, no grace bestowed, without his assent and participation. Meanwhile also Mary bore a son to Darnley; and after great preparations for the event, the baptism of the young prince was performed according to the rites of the Romish church. Darnley himself was soon after seized with the smallpox, or some dangerous distemper, the nature and cause of which are not very clear. He was at Glasgow when he was taken ill, having retired thither to his father somewhat hastily and unexpectedly. Mary was not with him, nor did she visit him for a fortnight. After a short stay they returned to Edinburgh together, when Darnley was lodged, not in the palace of Holyrood, as heretofore, but in the house of the Kirk of Field, a mansion standing by itself in an open and solitary part of the town. Ten days after, the house was blown up by gunpowder, and Darnley and his servants buried in the ruins. Whether Mary knew of the intended murder is not certain, and different views of the circumstances have been taken by different historians. The author of the horrid deed was Bothwell, and the public voice was unanimous in his reprobation. Bothwell was brought before the privy-council for the crime; but in consequence of the shortness of the notice, Lennox, his accuser, did not appear. The trial nevertheless proceeded, or rather the verdict and sentence; for, without a single witness being examined, Bothwell was acquitted. He was upon this not only continued in all his influence and employments, but he actually attained the great end which he had in view by the perpetration of the foul act. This was no other than to marry the queen herself, which he did in three months after; having in the interval met the queen, and carried her off a prisoner to his castle of Dunbar, and also raised a process of divorce against the lady Bothwell, his wife, on the ground of consanguinity, and got a decree in the cause just nine days before the marriage. Before the marriage, also, Mary created Bothwell duke of Orkney; and the marriage itself was solemnized at Holyrood-house by Adam Bothwell, bishop of Orkney, according to the forms both of the Romish and Protestant religions. [BOTHWELL.]

Public indignation could no longer be restrained. The nobles rose against Bothwell and Mary, who fled before an armed and indignant people from fortress to fortress. At length, after they had collected some followers, a pitched battle near Carbery Hill was about to ensue, when Mary abandoned Bothwell, and threw herself on the mercy of her subjects. They conducted her first to Edinburgh, and thence to the castle of Lochleven, where, as she still persisted to regard Bothwell as her husband, it was determined she should at once abdicate in favour of the prince her son James Instruments of abdication to that effect were accordingly prepared, and she was at last constrained to affix her signature to them; upon which the prince was solemnly crowned at Stirling, 29th July, 1567, when little more than a year old. Mary continued a prisoner at Lochleven; but by the aid of friends, in less than twelve months she effected her escape, and collected a considerable army. The battle of Langside ensued, where she was completely routed; upon which she fled towards Galloway, and thence passed into England, hoping to secure the favour of Elizabeth. In this however she was mistaken. Elizabeth refused her an audience, but declared her readiness to act as umpire between her and her subjects. Mary would not yield to this, or consent to be regarded in any other light than as queen of Scotland. The consequence was, that being now in the hands of her great rival, Elizabeth contrived to detain her a captive in her dominions till the end of the year 1586,—a period of about nineteen years,—when she was accused of being accessary to Babington's conspiracy against the queen of England. To try this accusation a commission was appointed by Elizabeth, but Mary refused to acknowledge its jurisdiction. 'I came into the kingdom,' she said, 'an independent sovereign, to implore the queen's assistance, not to subject myself to her authority. Nor is my spirit so broken by past misfortunes, or so intimidated by present dangers, as to stoop to anything unbecoming a crowned head, or that will disgrace the ancestors from whom I am descended, or the son to whom I leave my throne. If I must be tried, princes alone can try me: they are my peers; and the queen of England's subjects, however noble, are of a rank inferior to mine. Ever since my arrival in this kingdom I have been confined as a prisoner. Its laws never afforded me protection: let them not be perverted now, to take away my life.' Deluded however by the pretext that she would thus vindicate her character, Mary consented to be tried. The commission accordingly proceeded: Mary was condemned, and, on Wednesday the 8th of February, 1587, beheaded at Fotheringay castle, in the 45th year of her age. When about to enter the great hall which was prepared for her execution, she was allowed to stop and take farewell of the master of her household, Sir Andrew Melville, whom her keepers had not suffered to come into her presence for some weeks before. Melville kissed her hand, and kneeling down before her with tears in his eyes, declared this was the heaviest hour of his life. 'Not so to me,' said Mary: 'I now feel, my good Melville, that all this world is vanity. When you speak of me hereafter, say that I died firm in my faith, willing to forgive my enemies, conscious that I never disgraced my native country, and rejoicing in the thought that I had always been true to France, the land of my happiest years. Tell my son—,' and here she burst into a flood of tears, overcome by her feelings when she thought of her only child, the son of whom she had been so proud in his infancy, and whom she still loved notwithstanding his coldness and ingratitude,—'Tell my son, I thought of him in my last moments, and that I said I never yielded, by word or deed, to aught that might lead to his prejudice: tell him to remember his unfortunate parent; and may he be a thousand times more happy and prosperous than she ever was.' [ELIZABETH; JAMES I. of England.] She died professing the religion in which she had been brought up, and to her adherence to which many of her miseries may be traced.

For further particulars concerning Mary, and the love-letters, &c. which she is said to have written to Bothwell, we must refer to the writers who have minutely discussed the events of Mary's life. These writers are not few in number, from the time of Buchanan and Knox on the one hand, and Lesley, bishop of Ross, on the other, down to the present day, when Mr. Tytler's 'History of Scotland' is in course of issuing from the press. We may notice however Jebb's works on the subject, Anderson's 'Collections,' Goodall's 'Examination,' Tytler's 'Enquiry,' Whittaker, Laing, and Chalmers, and the 'Life of Mary,' by Henry Glassford Bell, which forms vol. 24 of Constable's 'Miscellany.'

MARY, wife of William III. [WILLIAM III.]

MARYBOROUGH. [QUEEN'S COUNTY.]

MARYLAND, one of the United States of North America, lies between 38° 3′ and 39° 42′ N. lat. and 75° 10′ and 79° 25′ W. long. It is divided into two portions by Chesa[illegible]ke Bay and the Susquehanna river. That portion which [illegible]ast of the bay is bounded on the south by Virginia for 15 [illegible]es; on the east by the Atlantic Ocean, which washes its shores for 35 miles; and by the state of Delaware, which extends 36 miles along its northern and 91 miles along its eastern boundary. Pennsylvania forms the whole northern boundary of this state, for 200 miles, along the parallel of 39° 42′. The western portion of Maryland is divided from Virginia by a straight line running north and south for about 36 miles, which constitutes the western boundary-line of Maryland. On the south, where it also borders on Virginia, the Potomac river, with its numerous windings and large æstuary, forms the boundary-line for 320 miles. The surface is calculated to be 10,000 square miles, or somewhat less than double the area of Yorkshire.

Surface and Soil.—The country east of Chesapeake Bay has a level surface as far north as Chester Bay, where it begins to be undulating, and towards the boundary of Pennsylvania isolated hills make their appearance. The soil is generally thin and sandy, but tolerably well cultivated. Along the shores both of the Atlantic and Chesapeake Bay marshy tracts of some extent occur. The largest is the Cypress Swamp, near the northern extremity of Sinepuxent Bay, a shallow arm of the sea, separated from the ocean by a ridge of low sand-hills, which however are intersected by some channels which form a communication between the bay and the ocean. Cypress Swamp partly belongs to Delaware, and is wooded. Along the eastern side of Chesapeake Bay several indentations occur, forming harbours for vessels of moderate size, as Pocomoke Bay, Fishing Bay, Choptank Bay, and Chester Bay. There are also several islands belonging to Maryland in Chesapeake Bay, of which the largest is Kent Island.

The country on the opposite shore of Chesapeake Bay is of the same description, but rather less fertile, its surface being mostly composed of a quartzose sand, without a sufficient quantity of clay to render it productive. But there are some productive tracts of considerable extent, as in the neighbourhood of Annapolis. North of the river Patapsco the country along the Chesapeake Bay is undulating, and possessed of a greater degree of natural fertility. About twenty miles from the shore the country rises into hills, which extend westward to the foot of the Blue Ridge, a part of the Appalachian range, a distance of about forty miles. In this hilly tract the fertility of the soil varies greatly; the extremes of fertility and sterility are frequently found in a very limited space. The country west of 77° 3[illegible]′ W. long. is mountainous, being traversed from south to north by six or seven of the ranges which compose the Appalachian system. The valleys which are enclosed by these ridges are generally wide and fertile; they are from 500 to 800 feet above the level of the sea. The ranges themselves are rather narrow, but they rise to an elevation of from 2000 to 2500 feet.

Rivers.—The Potomac rises within the Appalachian Mountains, with two branches: the northern branch rises in 39° 12′ N. lat., on the eastern declivity of the Backbone Range, and runs in a valley in a north-eastern direction thirty miles, when it suddenly turns south-east, and breaks through two chains of mountains in about ten miles of its course; it then runs again north-east to Cumberland, and has a course of twenty miles in a valley; deflecting again to the south-east, it traverses a mountain range, and twenty miles below Cumberland it is joined by the South Branch, which rises in the centre of Virginia, about 38° 2[illegible]′ N. lat., and runs north-east for about 100 miles in a valley enclosed between the Alleghany and Kittatinny chains, before it unites with the northern branch. After this junction the Potomac continues to flow in an eastern direction through mountain ranges with great rapidity, until it turns south-east, and before it breaks through the Blue Ridge, the most eastern chain of the Appalachian system, is joined from the south by the Shenandoah, the largest of its affluents, which rises in Virginia, near 38° N. lat., and flows over limestone rocks, in a wide and fertile valley between the Kittatinny and Blue Ridge, for about [illegible] miles. The united stream passes through the Blue Ridge at Harper's Ferry, by a gap which has all the appearance of being the effect of a violent disruption in the continuity of the mountain-chain. The river now enters the plain country, through which it flows in a south-east direction, with rather a rapid course: the last falls occur a few miles above Georgetown, to which place the tide ascends. Below the head of tide-water the Potomac becomes a deep and wide river, and, passing Washington and Alexandria, it has a general east-south-east course to the Chesapeake

Bay, which it enters in 38° N. lat. At the falls above Georgetown it is ten feet deep, and at Alexandria three fathoms; so that vessels of any burden can ascend to the latter place, and large vessels as far as Washington navy-yard. The whole course of the river exceeds 350 miles: large boats ascend it 50 or 60 miles above Harper's Ferry, and smaller ones much higher.

The Patuxent, the second largest river, rises on the eastern border of the hilly country, in 39° 20′ N. lat. Its general course varies between south-east and south, and it flows about 100 miles; towards its mouth it becomes a bay from two to three miles wide. It is navigable for vessels of 250 tons to Nottingham, forty-six miles from its outlet, and boats ascend fourteen miles higher, to Queen Anne's Town.

The Patapsco forms the harbour of Baltimore. This river likewise rises in the eastern portion of the hilly region, northwest of the source of the Patuxent; after a course of about thirty miles in an east-south-east direction, it falls over a ledge of rocks, and before it enters Chesapeake Bay it widens into an estuary ten or twelve miles in length. Vessels of 600 tons can sail to Fell's Point, the lower harbour of Baltimore, and boats may ascend to Elkridge Landing, eight miles above Baltimore.

The Susquehanna river traverses the northern part of Maryland for fifteen miles, before it falls into Chesapeake Bay.

Climate.—The climate is rather mild in the level part of the country, but the winter is severe enough to block up the harbour of Baltimore with ice for some weeks. In this town the range of the thermometer is from 7° to 98°; the mean annual temperature exceeds 52°, being about three degrees higher than that of London. In the level and hilly districts the summer-heat is modified by sea-breezes; but in the valleys between the mountains it is frequently insupportable. These valleys experience very severe winters, being from 800 to 900 feet above the sea-level. The prevailing winds blow from north-west and south-west. Rain is rather abundant, the mean annual fall amounting to about forty inches, and it occurs nearly in equal proportions throughout the year. Drought is rare.

Productions.—Wheat, Indian corn, and tobacco are chiefly cultivated; and rye, oats, and barley less extensively. Vegetables of various kinds are abundant. The common fruits of England, as apples, pears, plums, and peaches, succeed in most places, and are of good quality. Hemp and flax are raised to a considerable extent in the upper valleys. The whole country was originally covered with a dense forest, of which a considerable part still remains, composed of a great variety of trees, especially oak, hickory, ash, walnut, pine, and the tulip-tree. Along the coasts of the Atlantic and the adjacent swamps a wild grape grows, the fruit of which yields a pleasant wine.

The common domestic animals succeed well in Maryland. The wild animals have nearly disappeared from the plains, but in the forests on the mountains wolves, bears, and deer are still found. The wild turkey is still seen in the western districts. The land-tortoise is also common. Fish is abundant, especially in the Potomac.

The principal minerals are coal and limestone. Coal does not occur to the eastward of Cumberland, but west of that town it is abundant. It is found in beds which vary in thickness from one inch to several inches, and sometimes ten feet. Limestone occurs in the whole range of the mountains, and is used for different purposes; sometimes it supplies a good building marble. Iron-ore is met with in several places, and there are also indications of copper and lead.

Inhabitants.—The native tribes have long since disappeared in Maryland. The present population consists of whites and negroes. In 1820 it was composed of 260,223 whites, 39,730 free people of colour, and 107,398 slaves; in all, of 407,350 individuals. In 1830 it consisted of 344,046 free people, whites and coloured, and of 102,994 slaves, or of 447,040 souls. Since the importation of slaves into the United States has ceased, Maryland supplies slaves for the market of the southern states.

Roads and Canals.—A turnpike-road has been made across the country from Baltimore to Hagerstown, and thence to Cumberland and Wheeling in Virginia. The Chesapeake and Ohio canal is to connect Georgetown in the district of Columbia with Pittsburg on the Ohio, in Pennsylvania. It nearly follows the course of the Potomac, and in 1831 one hundred and ninety miles were completed, but it had not yet reached the coal region west of Cumberland. The difficulties in carrying the canal over the mountain-ridges suggested the construction of a railroad, which begins at Baltimore, and in 1834 was finished as far as Harper's Ferry; it is still in progress, but we are not informed how far it has advanced westward. Chesapeake Bay is united by a canal to Delaware River. This canal begins in Maryland on the Elk river, which flows into the most north-eastern corner of Chesapeake Bay, at some distance south of Elkton, and runs about thirteen miles to the Delaware river, where it terminates some miles south of Newcastle. It is calculated for sloop navigation, and has been more expensive than other canals, in consequence of a deep cut of about seventy feet for a considerable distance. A railroad connecting Baltimore with York in Pennsylvania is in progress; when terminated it will be 75 miles long. A branch of the Chesapeake and Ohio railroad runs to Washington; it is 32 miles long.

Political Division and Towns.—Maryland is divided into nineteen counties, of which eight are situated on the peninsula between Chesapeake and Delaware bays. The capital and seat of government is Annapolis [ANNAPOLIS], but the most commercial town is Baltimore. [BALTIMORE.] Other places of some importance are, Fredericktown, near the foot of the Blue Ridge, with 5000 inhabitants and a considerable trade in the produce of the country, it being situated on the turnpike-road to Wheeling; Cumberland on the Potomac, in the centre of the mountain-region, has 2000 inhabitants, who carry on trade in iron, lead, and coal. In the eastern districts the largest town is Easton, with 1500 inhabitants and some commerce. Chester and Snowhill are still less important.

Education.—The institutions for the education of the higher classes are rather numerous. As to those in Baltimore, see BALTIMORE, vol. iii., p. [illegible]. There are also St. John's College at Annapolis, and Mount St. Mary's College in Frederick county. The schools for the lower classes are also numerous, and the State has granted considerable sums for their support.

Manufactures are rather numerous, but chiefly concentrated in the neighbourhood of Baltimore. The principal articles made are iron utensils, woollen and cotton goods, hats, paper, ropes, leather, sugar, and tobacco. Vessels are built at Baltimore and Annapolis.

Commerce.—The maritime commerce is almost entirely in the hands of the inhabitants of Baltimore, Annapolis and Easton having only a small portion of it. The exports consist of flour, wheat, rye, and Indian-corn, flax-seed and flax-seed oil, salt beef and pork, butter, hog's lard, whiskey, lumber, and a considerable quantity of tobacco, which is greatly esteemed in the European market. The imports are colonial merchandise from the West Indies, wines and spirituous liquors, tea and spices, hardware and some other manufactured goods. The value of the imports from 1st of October, 1832, to the 30th of September, 1833, amounted to 4,437,647 dollars, and the exports to 4,079,167. This commerce employed 155,323 tons of shipping, of which 82,642 entered the ports, and 72,680 cleared out. Two-thirds of this amount of shipping belonged to the United States, and the remainder were foreign vessels. The shipping of Maryland is more than 80,000 tons, of which nearly 40,000 belong to Baltimore.

History.—Maryland was first settled as a place of refuge for the persecuted Roman Catholics of England by Lord Baltimore [BALTIMORE, LORD] in 1634, when 200 Roman Catholics established themselves at St. Mary's, and the country received the name of Maryland from Henrietta Maria, the wife of Charles I. The numbers of settlers soon increased, not only by emigration from England, but also by the addition of non-conformists from New England and Virginia. During the commonwealth the oppression of the Catholics retarded the growth of Maryland, though it enjoyed a more liberal constitution than the other colonies. In 1692 the seat of government was fixed at Annapolis, where it has ever since remained. The constitution of the state was adopted in 1776, and has since been often amended. The legislative body consists of two assemblies, a senate and house of delegates. The members of the senate, fifteen in number, are chosen by forty electors. These electors, who are two for each county, and one for each of the cities of Annapolis and Baltimore, are chosen by the citizens, and elect the senators by ballot out of their own body, or from the mass of citizens. The senators serve for five years. The members of the house of delegates are annually chosen by all the citizens, four for each county, and two for each of the cities of Annapolis and Baltimore. The executive power is vested in a governor and council, consisting of five members, who are elected annually by the joint ballot of the two legislative bodies. Maryland sends two senators and eight representatives to congress.

MARYLEBONE. [LONDON.]

MARYPORT. [CUMBERLAND.]

MASA'CCIO, called **MASO DA SAN GIOVANNI,** one of the earliest painters of the Florentine school, was born at San Giovanni in Val d'Arno, in the year 1401, and died in 1443. He was a disciple of Masolino da Panicali, to whom he proved as much superior as his master was to all his contemporaries. He had great readiness of invention, with unusual truth and elegance of design. He made nature his constant study; and he gave in his works examples of that beauty which arises from a judicious and pleasing choice of attitudes, accompanied with spirit, boldness, and relief. He was the first who studied to give more dignity to his draperies, by designing them with greater breadth and fulness, and omitting the multitude of small folds. He was also the first who endeavoured to adapt the colour of his draperies to the tints of his carnations, so that they might harmonise with each other.

He was remarkably well skilled in perspective, which he was taught by P. Brunelleschi. His works procured him great reputation, but excited the envy of his competitors. He died, to the regret of all lovers of the art, not without strong suspicions of having been poisoned. Fuseli says of him—'Masaccio was a genius, and the head of an epoch in the art. He may be considered as the precursor of Raphael, who imitated his principles, and sometimes transcribed his figures. He had seen what could be seen of the antique in his time at Rome, but his most perfect works are the frescos of S. Pietro del Carmine at Florence, where vigour of conception, truth and vivacity of expression, correctness of design, and breadth of manner, are supported by truth and surprising harmony of colour.'

MASANIELLO. [ANIELLO.

MASCAGNI, PAUL, was born in 1752. He studied medicine in the university of Siena, and in 1774 succeeded his master, Tabarani, in the professorship of anatomy in that institution. He is chiefly celebrated for his admirable work on the absorbent system, and the beauty of his anatomical preparations, of which the greater part are preserved in the Anatomical Museum of Florence. An outline of his great work was published in 1784 in French, under the title, 'Prodrome d'un Ouvrage sur le Systême des Vaisseaux Lymphatiques,' and was sent to the Académie des Sciences in competition for a prize offered for the best essay on the subject. In 1787 the more complete work, 'Vasorum Lymphaticorum Corporis Humani Historia et Ichnographia,' was published in folio at Siena. It contains twenty-seven large plates, finished and in outline, of the lymphatics in different parts of the body, engraved with extreme delicacy by Cyro Sancti. It was dedicated to the reigning duke of Tuscany, under whose patronage Mascagni afterwards rapidly advanced in reputation. In 1800 he left the university of Siena for that of Pisa, and the year after went to that of Florence. He died in 1815.

After his death two large works were published from his papers, 'Anatomia per uso degli Studiosi di Scultura e Pittura,' Florence, 1816, and 'Prodromo della Grande Anatomia,' Florence, 1819, by Antommarchi. Mascagni also published works of some celebrity on the lagunes and hot-springs of Tuscany, and on the cultivation of the potato and other branches of agriculture, to which he devoted all his leisure time.

MASCAGNIN, volcanic sulphate of ammonia, occurs stalactitic and pulverulent. Colour yellowish or greyish; taste acrid and bitter; translucent or opaque. Volatilized entirely at a high temperature. Occurs among the lavas of Etna and Vesuvius, &c.

By the analysis of Gmelin it contains—

Sulphuric acid . . .	53·29
Ammonia . . .	22·80
Water	23·91
	100·

MASCLEF, FRANCIS, was born at Amiens, in the year 1662. He very early devoted himself to the study of Oriental languages, in which he attained an extraordinary degree of proficiency. Having been brought up to the church, he became first a curate in the diocese of Amiens, and afterwards obtained the confidence of De Brou, bishop of Amiens, who placed him at the head of the theological seminary of the district and made him a canon. De Brou died in 1706, and Masclef, whose opinions on the Jansenist controversy were not in accordance with those of the new prelate Sabbatier, was compelled to resign his place in the theological seminary and to retire from public life. From this time he devoted himself to study with such close application as to bring on a disease, of which he died, on the 24th of November, 1728, at the age of sixty-six. Though austere in his habits, he was amiable and pious.

Masclef's chief work is the 'Grammatica Hebraica, à punctis aliisque inventis Massorethicis libera,' in which he embodied an elaborate argument against the use of the vowel points. The first edition was published in 1716, and speedily called forth a defence of the points from the Abbé Guarin, a learned Benedictine monk. In the year 1731 a second edition of Masclef's work was published at Paris, containing an answer to Guarin's objections, with the addition of grammars of the Syriac, Chaldee, and Samaritan languages. This work still ranks as the best Hebrew grammar without points. The other works of Masclef were, 'Ecclesiastical Conferences of the Diocese of Amiens;' 'Catechism of Amiens;' and, in MS., 'Courses of Philosophy and Divinity.' The last-mentioned work was not printed, on account of its being thought to contain Jansenist opinions.

MASCULINE and NEUTER. [GENDER.]

MASERES, FRANCIS. The dates and facts in the following account are taken from 'The Gentleman's Magazine' for June, 1824.

He was born in London, December 15, 1731. His father was a physician, descended of a family which was driven out of France by the revocation of the Edict of Nantes. He was educated at Clare Hall, Cambridge, and took the degree of B.A. in 1752, obtaining the highest place, both in classics and mathematics. He then (having first obtained a fellowship in his college) removed to the Temple, was in due time called to the bar, and went the Western circuit for some years with little success. He was then appointed (the date is not mentioned) attorney-general for Canada, in which province he remained till 1773, distinguished 'by his loyalty during the American contest, and his zeal for the interests of the province.' On his return in 1773 he was appointed cursitor baron of the Exchequer, which office he held till his death. He was also at different times deputy recorder of London and senior judge of the sheriff's court. He died May 19, 1824, at Reigate, in the 93rd year of his age.

Baron Masères (as he was commonly called) has left behind him a celebrity arising partly from his own writings and partly from the munificence with which he devoted a part of his income to reprinting such works as he thought useful, either in illustration of mathematical history or of that of his own country. These were the objects of his private studies, and a peculiarity of his mathematical views which tinctured the whole of his writings, as well as his selection of works to be reprinted, requires some explanation.

It is well known that the art of algebra grew faster than the science, and that, at the time when Masères began his studies, a branch of knowledge which is essentially distinct from arithmetic, or rather of which arithmetic is one particular case, had been pushed beyond the simple science of numbers in its methods, reasonings, and results, while its fundamental definitions were allowed to be expressed in arithmetical language, and restricted by arithmetical conceptions. [NEGATIVE AND IMPOSSIBLE QUANTITIES.] The consequence was, that the algebraical books were anything but logical; and while those who could make for themselves the requisite generalization at the proper time were more likely to employ themselves in extending the boundary of the science than in writing elementary works, all other students had to take a large part of algebra on trust, their faith being built partly on authority, partly on continually seeing verifiable truths produced by its operations. Masères, when a young man, rejected all of algebra which is not arithmetic, as being what he could not comprehend himself, though he admitted that others might do so. In his earliest publication but one ('Dissertation on the Use of the Negative Sign in Algebra,' London, 1758), which is in fact a treatise on the elements of algebra, after rejecting an equation in which negative quantities occur, he adds: 'I speak according to the foregoing definition, by which the affirmativeness or negativeness of any quantity implies a relation to another quantity of the same kind, to which it is added, or from which it is subtracted; for it may perhaps be very clear and intelligible to those who have formed to themselves some other idea of affirmative and negative quantities different from that above defined.'

The other works of Maseres are, 'Elements of Plane Trigonometry,' London, 1760; 'Principles of the Doctrine of Life Annuities,' London, 1783; Appendix to Frend's 'Principles of Algebra,' 1799; tracts on the Resolution of Equations, 1800; various remarks on the tracts published in the '*Scriptores Logarithmici*,' presently to be noticed; papers in the 'Philosophical Transactions;' and political writings, a list of which will be found in the 'Gentleman's Magazine' above cited. The characteristic of all these writings is an extreme prolixity, occasioned by his rejection of algebra, and the consequent multiplication of particular cases. In his 'Dissertation,' &c. above noticed, the four rules, and the solution of equations of the second and third degree, occupy three hundred quarto pages.

Of the reprints which Baron Maseres made at his own expense, the most important is the 'Scriptores Logarithmici,' a collection, in six volumes quarto, published in various years from 1791 to 1807, of writings on the subject of logarithms. Here we find the works of Kepler, Napier, Snell, &c., interspersed with original tracts on kindred subjects. The republication of these old writings has put them in the way of many students to whom they would otherwise have been inaccessible, and has thus tended to promote historical knowledge and to excite inquiry. The '*Scriptores Optici*,' 1823, a reprint of the optical writings of James Gregory, Descartes, Schooten, Huyghens, Halley, and Barrow, has a merit of the same kind: it was begun at an earlier period, but having been delayed by circumstances, was completed under the superintendence of Mr. Babbage. Besides these, he also reprinted the tract of James Bernoulli on Permutations and Combinations, and discovered and printed Colson's translation of Agnesi's 'Analytical Institutions.' He also reprinted a large number of tracts on English history. The expense of Hales's Latin treatise on Fluxions, 1800, was defrayed by him, and we understand that more than one other author was indebted to him for assistance of the same kind.

MASHAM, ABIGAIL, the favourite of Queen Anne, noted in the history of the time for her political intrigues, was the daughter of Francis Hill, a Levant merchant of London, who married the sister of Mr. Jennings, the father of the Duchess of Marlborough. Upon the bankruptcy of her father she became the attendant of a baronet's lady, whence she removed into the service of her relative, then Lady Churchill, who procured her the place of waiting-maid to the Princess Anne. She retained her situation after the princess ascended the throne, and by her assiduity and complaisance acquired a great degree of influence over her. The high church principles in which she had been educated contributed to increase her credit with the queen, who was secretly attached to the tory party, though obliged, in the beginning of her reign, to favour the whigs. The marriage of Miss Hill with Mr. Masham (son of Sir Francis Masham, of Oates in Essex) in 1707, occasioned an open quarrel with the Duchess of Marlborough, who was, in consequence of it, deprived of her majesty's confidence. Harley, afterwards earl of Oxford, connected himself with the new favourite; a change of ministry took place, and in 1711 Mr. Masham was raised to the peerage. He and his wife appear to have been actively engaged in the intrigues of the tories in favour of the exiled House of Stuart. Lady Masham lived a long time in retirement after the death of the queen, and died herself at an advanced age, December 6, 1734.

(*Life of Sarah, Duchess of Marlborough*, 8vo., London, 1745, p. 48; *Polit. State of Brit.*, vol. xlviii., p. 624; see also a character of Mr. Masham in Manley's *Secret Memoirs from the New Atalantis*, 12mo., London, 1709, vol. ii., p. 147.)

MASKELYNE, NEVIL, was born in London, October 6, 1732, was educated at Westminster, and afterwards at Catherine Hall and Trinity College, Cambridge, in which university he took the degree of B.A., with distinction, in 1754. In 1755 he took orders, but he had previously been led to turn his attention to astronomy by the solar eclipse of 1748, and by becoming acquainted with Bradley, whom he assisted in the formation of his tables of refraction. In 1761 he went to St. Helena, to observe the transit of Venus, and to detect, if possible, the parallax of the fixed stars. In this voyage, and in one undertaken to Barbadoes in 1764 to try the merits of Harrison's new chronometers, he acquired that knowledge of the wants of nautical astronomy, which afterwards led to the formation of the Nautical Almanac. In 1765 he was appointed to succeed Mr. Bliss as astronomer royal, and from this time, with the exception of his voyage to Scotland in 1774, to determine the mean density of the earth by observing the effect of the mountain Schehallien upon the plumb-line, his life was one unvaried application to the practical improvement of astronomical observation. He died February 9, 1811.

Delambre dates the commencement of modern astronomical observation, in its most perfect form, from Maskelyne, who was the first who gave what is now called a standard catalogue (A.D. 1790) of stars, that is, a number of stars observed with such frequency and accuracy, that their places serve as standard points of the heavens. His suggestion of the Nautical Almanac, and his superintendence of it to the end of his life, from its first publication in 1767, are mentioned in ALMANAC (vol. i., p. 364); his Schehallien experiment, in ATTRACTION (vol. iii., p. 69); and the character of his Greenwich observations, in GREENWICH OBSERVATORY (vol. xi., p. 432).

Dr. Maskelyne, as arbitrator on the part of the government of the merits of the chronometers which were submitted by their makers as competitors for the prize, had more than one public accusation of partiality to bear. The now celebrated Harrison was one of his oppugners, and Mr. Mudge, junior, on the part of his father, another. The only publication (as far as we know) which he ever made out of his official capacity (with the exception of papers in the 'Philosophical Transactions'), was a reply to a pamphlet by the latter, London, 1792. He edited Mayer's lunar tables, and was the means of five thousand pounds being awarded to the widow of the author.

MASON, WILLIAM, born in 1725, was the son of a clergyman at Hull. He took his B.A. degree at Cambridge in 1745, after which he removed from St. John's College to Pembroke, of which college he was elected fellow in 1747. Having taken orders, he was presented to the rectory of Aston in Yorkshire, and became chaplain to the king. His political principles strongly opposed him to the American war, and he was a member of the Yorkshire association for obtaining reform of parliament. The horrors of the French Revolution however are said to have caused a change in his opinions, but as he was growing an old man when it broke out, the timidity of age probably worked as strongly as the reign of terror. He died in 1797, aged 72, having been for years precentor and canon-residentiary of York. There is a tablet to his memory in Poets' Corner, Westminster Abbey.

Mason's Poems are now almost forgotten. Two tragedies, 'Elfrida' and 'Caractacus,' a descriptive poem called 'The English Garden,' and some odes, are his principal productions, but he is now perhaps best remembered as Gray's biographer and friend. His style is that of an imitator of Gray, and not being so perfect an artist in language as his master, he has been proportionally less successful. In addition to his poetical reputation he possessed considerable skill in painting and music, and in the latter subject entertained opinions not at all consonant to those of musicians in general. He wished to reduce church music to the most dry and mechanical style possible, excluding all such expression as should depend on the powers and taste of the organist. (*Mason's Compendium of the History of Church Music.*)

MASONRY (from the French *maçon* and *maçonner*) signifies both the operation of constructing with stone and the parts of a building consisting of such material. It is a most important branch of architectural practice, because much, both of the durability and beauty of an edifice so constructed, depends upon the excellence of the workmanship and the quality and colour of the stone. Owing to its expense, masonry is comparatively rarely employed in this country, except for public buildings or others of the highest class, the mason's work being in other cases restricted to such parts as steps to doors, string-courses, facias, and plain cornices externally, and to pavements and stairs in the interior. Yet that degree of stone-work does not constitute what is termed a brick and stone building, because such term implies a considerable mixture of stone and brick, namely, that the doorways, window dressings, columns, parapets, angle-quoins, and all the ornamental parts are of stone, the *nude* or plain face of the wall only being of brick. But such mode is now fallen into disuse, except for buildings in some of the later Gothic styles, the brick-work being now covered with stucco, cement, or mortar, to resemble as far as possible the stone, when the latter is used for columns, pilasters, and ornamental parts; or, as is now more frequently the case, the whole, even the columns themselves are formed of brick, and afterwards stuccoed. In other instances, while the building itself is entirely faced with stone, all the richer and more elaborate decorations, such as capitals, carved mouldings, and other sculptured ornament, are composed of terra-cotta, or burnt artificial composition, which is said to be not only more economical, but far more durable than stone itself, owing to its being to a certain extent vitrified. This mode has been resorted to with great success for the Ionic capitals of St. Pancras Church, London.

Of all our freestones, Portland stone is perhaps the very best yet discovered, both for durability and colour; but its high price and the expense of working it prevent its being so often employed as could be wished. Of late years therefore Bath stone is the kind more generally made use of for building purposes, it being soft when first taken out of the quarry, and very easily worked. Neither its texture nor tint however is so good; and when discoloured by time, as is quickly the case, it has a certain shabbiness of appearance. In fact a living architect (Mr. A. Bartholomew) describes it, in his 'Hints on Fire-proof Buildings,' as 'the vilest of material, which, when new, is mean and swarthy, and which decays before I myself am old;' and he further mentions St. Bartholomew's Hospital as the earliest instance of the extensive use in London of Bath stone. Ketton stone, which has been used for the tower of St. Dunstan's in the West, Fleet Street, is, though not equal to Portland, greatly superior to Bath stone. Cornwall granites and Dundee stone are now in great requisition for constructions demanding strength and solidity, and have been used in several of the docks and new bridges.

Walls which are not of solid masonry throughout, but built either of brick or inferior stone and rubble, with only an external facing of squared stone laid in courses, are termed *ashler*, or *ashlering*. [ASHLER.]

Rusticated ashler or stone work is that where the separate stones are divided at their seams or joints, which is done either by bevelling off or chamfering their *arrises* or edges to a certain depth, or sinking them by cutting each stone so that it has a general projecting surface, by which means, when united together, those surfaces are flush with the plane of the wall, and the sunk margin round each forms rectangular grooves or channels between them. This latter mode is always adopted when horizontal rustics alone are used, as is now too frequently the practice, for it is not only poor and monotonous, in comparison with rusticating with both vertical and horizontal joints, but unmeaning in itself, and therefore justly condemned by Sir W. Chambers. Though generally made quite smooth, the faces of the rustics are sometimes tooled, or else, though very rarely, *hatched*, *vermiculated*, or *frosted;* all which varieties may likewise be combined, with exceedingly good effect and great diversity, with smooth-faced rustics. Such rough rustics are sometimes distinguished by the name of *bossages*.

Stones inserted quite through a wall, in order to bind it firmly together (in the absence of which the ashlering would be a mere external coating, adhering to the brick-work only by mortar), are called *bond stones;* and those at the base of the wall, projecting beyond its general plane, for the purpose of giving greater solidity just above the foundation, are termed *footings*.

Walls built with unhewn stones, either with or without mortar, are called *rubble walls*, and the stone itself rubble.

MASONS, FREE. According to the extravagant and whimsical hypotheses entertained by some of those who have written upon the subject of freemasonry, it is an institution of almost incredible antiquity. We are told by some that it originated with the builders of the tower of Babel, though others are content with tracing it no farther back than the temple of Solomon. If we are to believe them, the institution has been continued down in uninterrupted succession from that very remote time to the present day, through all the changes of governments, religion, civilization, and knowledge. Against this there exists one very simple, yet fatal, argument, namely, that were this really the case, such an uninterrupted series of tradition must have kept alive and handed down to us much information that has, on the contrary, been utterly lost. Instead of accumulated knowledge, we find that even a technical knowledge of architecture itself has not been so preserved; else how are we to account for the ignorance which everywhere prevailed with respect to Gothic architecture and its principles almost as soon as the style itself fell into disuse? That there may have been many points of resemblance between the fraternities of masons in the middle ages, and such institutions as those of the Eleusinian mysteries, and the corporation of Ionian architects, is not only possible, but highly probable, because similarity of circumstances would almost necessarily lead to it. Before the invention of printing, when the means of communicating knowledge were few and imperfect, no readier mode presented itself of extending and keeping up the speculative and practical information spread among any profession, than by establishing the profession itself into a community or order, all the members of which would have one object and one interest in common. This would be more particularly the case with regard to architecture, which calls for the co-operation of various branches of science and the mechanical arts, and was moreover for several ages the paramount art, all the other arts of decoration being, as far as they then existed, subservient to it.

The importance of architecture to the church, on account of the impressive dignity it conferred upon religious rites and the ministers of religion, naturally induced the clergy to take it under their especial protection. For a long time not only were ecclesiastics the chief patrons but almost the chief professors of the art; yet as they had occasion for the assistance of practical artificers in various branches, they admitted them into fellowship with themselves, establishing a kind of order of a mixed character, just as the orders of chivalry combined at their origin the principles of military and religious discipline. Hence some have supposed freemasonry to have been a branch of chivalry, and to have been established at the time of the Crusades. The more probable hypothesis perhaps is that they were related to each other only in emanating from the same source—from the influence of ecclesiastical power; and their being so derived would alone account for the mystery and secrecy which the guilds of masons affected; and, together with their zeal in accumulating knowledge for themselves, the desire to confine it to their own body.

By means of these associations the inventions and improvements made in architecture were communicated from one country to another, a circumstance which at once accounts for the sudden spread of pointed or Gothic architecture throughout the whole of the west of Europe; and at the same time renders it so exceedingly difficult to determine at all satisfactorily where that style actually originated, or what nation contributed most towards its advancement. Owing also to the jealousy with which the masons kept their knowledge to themselves, it is not at all surprising that the history of the art during the middle ages should be involved in so much obscurity that it can now be traced only by its monuments, all documents relative to the study of it having been concealed as much as possible, even when something of the kind must have been in existence. Among the causes which led afterwards to the decline of these institutions was, on the one hand, the suspicion with which the church itself began to regard them as societies that might in time acquire an influence not easily watched, and which might be turned against itself; and on the other, the spread of information, together with the revival of the arts, which deprived such bodies of their utility and importance, and rendered it impossible for them to confine their knowledge exclusively within their own pale.

In this country an act was passed against Masonry in the third year of Henry VI., at the instigation of the bishop of Winchester. It was however never enforced, and Henry himself afterwards countenanced the brethren by his presence at lodges of masons. It was also patronised by James I. of Scotland: but it was no longer indispensable to the church, which accordingly withdrew its protection—an event which would otherwise have been occasioned by the Reforma-

Freemasonry revived again in this country about the time of the civil war, yet merely in semblance, being altogether different in object and character from what it had been, and becoming merely 'speculative' or modern Masonry, or masonry in no wise connected with architectural practice. From this country it was first introduced into France about the year 1725; into Spain in 1726, and into Italy in 1733, when the first masonic lodge was established at Florence. It was afterwards however the object of persecution not only in France and Italy, but also in Holland and Germany. Some writers, more especially Abbé Barruel and Professor Robison, have made it a charge against freemasonry that it has been converted into an organized secret conspiracy against religion and existing governments. If that charge has been unjustly made, it must be owned that the profound mystery in which it has cloaked itself gave some colouring to such charges, it being but natural to infer that if there was nothing to call for such extraordinary degree of secrecy, it could hardly be sought for good, or in accordance with the interests of society at large. The greater probability is that there is nothing either good or bad to conceal; that the mystery of freemasonry is nothing more than an innocent mystification; and that its symbols and institutions, whatever meaning or purpose they may originally have had, are now become mere forms and signs retained by the brethren or 'free and accepted masons,' as they style themselves, for the purpose of conferring peculiar importance on their harmless social meetings.

MASORITES. [Hebrew Language.]

MASOVIA. [Poland.]

MASQUE. [English Drama.]

MASQUERADE (from the Italian *mascherata* and French *mascarade*), an amusement introduced into England in the sixteenth century from Italy. Hall, in his 'Chronicle,' says, 'On the daie of the epiphanie, at night (A.D. 1512-13), the king (Henry VIII.) with eleven others were disguised after the maner of Italie, called a maske, a thing *not seen afore in Englande*: thei were apparelled in garmentes long and brode, wrought all with golde, with visers and cappes of golde; and after the banket doen, these maskers came in with the six gentlemen disguised in silke, bearing staffe torches, and desired the ladies to daunce: some were content; and some that knewe the fashion of it refused, because it was not a thing commonly seen: and after thei daunced and commoned together, as the fashion of the maske is, thei toke their leave and departed, and so did the quene and all the ladies.'

The distinction between this species of amusement and the disguisings and mummings of the middle ages appears to have been the general mingling of the company in dance and conversation, in lieu of the execution of a particular dance or preconcerted action by certain individuals for the entertainment of the guests, the latter being as old at least as the time of Edward III. in England, and the precursors of the dramatic masque of the sixteenth century. In 'the garmentes long and brode,' and 'disguisings of silke,' we may perceive the present *domino*, so called, according to some authorities, from an ecclesiastical vestment (a black hood worn by canons of cathedrals), *dominus* being a title applied to dignified clergymen in the middle ages. Others derive it from the ordinary robe or gown worn by Venetian noblemen at that period. Granacci, who died in 1543, is said to have been the inventor of masquerades: at what particular date does not appear; but from the above evidence of Hall, they had become fashionable in Italy as early as 1512.

MASS. By the mass of a body is meant the quantity of matter which it contains, upon the supposition that differences of weight are always the consequence of different quantities of matter. This involves an hypothesis: for instance, if gold be, bulk for bulk, nineteen times as heavy as water, it is presumed that a given bulk of gold contains nineteen times as much matter as the same bulk of water. Now it is possible that if we were better acquainted with the constitution of these bodies, it might appear that we are wrong in supposing difference of quantity to be the cause of difference of density.

The fact is, that mass means weight, so that of two bodies, the heavier is that which has the more mass; why then is this word introduced at all? If we had only to consider bodies at the surface of the earth, we might in all cases substitute weights for masses, but when we have occasion to speak of bodies at very different distances from the centre of the earth, their weight towards the earth, which is then called the attraction of the earth, depends upon their distance from the earth, as well as their absolute constitution. If we imagine two planets at the same distance from the earth, the attractions of the earth upon the two will then be in a proportion which depends, not on that distance, but on the amount of matter in the two planets.

When we say that Jupiter has only the 1047th part of the mass of the sun, we express—1, a fact of which observation and deduction make us certain, namely, that at the same distances the attraction of the sun upon the earth is 1047 times as great as that of Jupiter upon the earth; 2, an hypothesis of the following kind, that the sun contains 1047 times as much matter as Jupiter. The hypothesis is a convenience, not affecting the truth or falsehood of results; the fact represented remains, that at the same distances the sun does 1047 times as much towards deflecting the earth as is done by Jupiter.

In the application of mechanics, the following equations frequently occur:—

Weight = mass × force of gravity.

Mass = volume × density.

These equations, like others of the same kind, are to be understood with tacit reference to the units employed; they spring from the following propositions. Any two masses are to one another in the ratio compounded of that of the volumes and that of the densities; thus the two bodies being eight cubic feet three times as dense as water, and seven cubic feet four times as dense, the masses are in the proportion of 8 × 3 to 7 × 4, or of 24 to 28. Again, if two different masses be acted upon by pressures which would, in a unit of time, create different amounts of velocity, the pressures are to one another in the ratio compounded of that of the masses and that of the velocities which would be generated in the unit of time. Thus if the preceding masses, which are as 24 to 28, were subjected to attractions which would produce in single particles velocities of 10 and 11 feet, if allowed to act uniformly for one second, the pressures requisite to prevent motion at the outset would be as 24 × 10 to 28 × 11, or as 240 to 308.

To convert these proportions into equations, let the unit of time be one second, that of volume one cubic foot, and let water be the substance which has the unit of density; also let the unit of length be one foot. Then if the unit of mass be one cubic foot of water, and the unit of weight the pressure necessary to restrain a unit of mass acted on by an attraction which would, in one second, give a velocity of one foot per second, the preceding equations are true. [Weight; Specific Gravity; Acceleration.]

MASS (*Missa*, in Latin). The derivation of the word 'mass' has been variously accounted for; some derive it from missio or dimissio, 'dismissal,' because in the early ages of the church the catechumens, or new converts who were not yet admitted to partake of the sacrament, were sent out of the church after the liturgy was read, and before the consecration of the Host. Others derive it from the Hebrew word 'Missah,' *i.e.* oblation or sacrifice in commemoration of the sacrifice of our Redeemer for the sins of mankind. Ducange, in his 'Glossarium,' art. 'Missa,' gives the various opinions on the etymology of the word. The word missa, signifying the ceremony or rite of consecrating the Host, is found in the epistles of St. Ambrose, St. Augustine, and Cæsarius, bishop of Arles. See also Baronius, in his 'Annals.'

The mass is a church service which forms an essential part of the ritual of both the Roman Catholic and Greek or Eastern churches, and in which the consecration of the sacramental bread and wine takes place. It is performed entirely by the officiating priest standing before the altar, and attended by a clerk who says the responses. The prayers of the mass are all in Latin in the Roman Catholic church, in ancient Greek in the Eastern church, and in Syriac among the Maronites and Jacobites, but never in the vulgar or vernacular tongue of the country. The congregation take no ostensible part in the service, but they follow it mentally or in their prayer-books, in which the text of the prayers is occasionally accompanied by a translation in the vulgar tongue. The priest does not address the congregation, but has his back turned to them, except at the end of certain prayers, when he turns round, and says, 'Dominus vobiscum' ("The Lord be with you"), and at the 'Orate Fratres,' &c. ("Brethren, pray," &c.), which are responded to, on the part of the congregation, by the clerk.

The mass consists of various parts—1, the Introitus, or preparation, consisting of several prayers, psalms, the 'Gloria in excelsis,' the epistle and gospel for the day, the Creed, &c., which the priest recites with a loud voice. 2, The consecration, in which the priest consecrates the bread and wine, repeating the words, 'Hoc est corpus meum, et hic est calix sanguinis mei,' and then shows to the people both the bread and the chalice containing the wine, upon which all the congregation kneel down. 3, The Communion. The priest, after reciting more prayers, accompanied by an invocation of the apostles and other saints, the Lord's Prayer, &c., takes the sacrament under both forms; if any of the congregation are disposed to take the sacrament, the priest then descends from the altar and administers it to them in the shape of the consecrated wafers or bread only. 4, The post communio, which consists of a few more prayers, and of the blessing which the priest gives turning towards the congregation, after which he reads the first chapter of the gospel of St. John down to the fourteenth verse, and the mass is over.

The low or ordinary mass, *Missa brevis*, lasts in general about half an hour, and every Roman Catholic is bound, by what are styled the 'Commandments of the Church,' to attend it once at least on Sundays and other holidays, unless prevented by illness. The transgression of this precept is reckoned a sin. Pious persons hear several masses in succession, and many attend mass every day in the week, for it is celebrated every day in each parish church. A priest must not break his fast either by food or drink from the previous midnight until he has said mass, out of respect for the real presence of Jesus Christ in the sacrament. The service of the mass is indeed essentially connected with and depends on the doctrine of transubstantiation. [TRANSUBSTANTIATION.]

On great festivals and other solemn occasions the mass is performed by a priest or prelate, attended by a deacon and subdeacon, who says the responses and chants the epistle and gospel of the day. On those occasions the mass, or at least parts of it are sung by a choir, accompanied by the organ and other musical instruments. This is called 'high mass,' and is a long and pompous service. Both for the low and the high masses the officiating priest is dressed in peculiar various-coloured garments appropriated to the occasion, which he afterwards takes off in the vestry-room.

The 'Missale' is the name of the book which contains the ritual of the mass, and which the priest holds open before him on the altar. Some of the old Missals, whether MSS. or printed, are beautifully ornamented with paintings, and are valued as bibliographic curiosities.

The Protestant and reformed churches have no mass, as they do not believe in the doctrine of transubstantiation; but several of the detached 'Oremus,' or prayers of that service, which are very fine, have been retained in the Liturgy of the Church of England translated in the vulgar tongue.

MASSA, DUCHY OF, a small territory on the west coast of Italy, which, with the annexed territory of Carrara, constituted for a long time a sovereign principality under the family of Cibo. It now belongs to the duke of Modena. [CARRARA.] The territory of Massa extends about eight miles from the sea-coast to the Alpe Apuana or mountain-group which divides it from the province of Garfagnana, part of which also belongs to Modena. [GARFAGNANA.] To the south-east Massa borders upon the territory of Pietra-santa, belonging to Tuscany; and on the north-west it adjoins Carrara: its breadth between these two limits hardly exceeds six miles. The small river Frigido flows through the territory of Massa from the mountains of Carrara to the sea. The town of Massa is in the lower part of the country, not far from the sea, on the high road from Genoa to Lucca and Pisa. It is surrounded by fine gardens and plantations of fruit-trees. Massa is a neat town: it is also a bishop's see, has a cathedral with some good paintings, a town-house, a fine public garden with orange-trees, and a handsome marble bridge over the Frigido. It is the residence of the governor sent from Modena, and has a court of appeal for the duchy of Massa and Carrara. Massa and its territory contain from 9000 to 10,000 inhabitants.

MASSACHUSETTS, one of the United States of North America, lies between 41° 31′ and 42° 52′ N. lat. and 69° 50′ and 73° 50′ W. long; but the two islands of Martha's Vineyard and Nantucket, which belong to it, extend as far south as 41° 12′. The Atlantic Ocean washes its eastern and southern shores to the extent of 270 miles, if the numerous inflexions and inlets are taken into account. On the south, Massachusetts is bounded by Rhode Island, with which it has a common boundary-line of 69 miles, and by Connecticut, which forms its boundary for 85 miles. On the west the boundary-line formed by New York rather exceeds 50 miles. North of Massachusetts are Vermont and New Hampshire, which respectively form its boundary for [illegible] and 85 miles. Its length from Plymouth harbour on Cape Cod Bay, along the southern border to New York, is about 145 miles, and its mean width about 50 miles. Its surface is 7335 miles, or nearly the area of Wales.

Shores and Islands.—Narraganset Bay, which lies chiefly within the state of Rhode Island [RHODE ISLAND], enters by its most north-eastern inlet into Massachusetts, where it receives the Taunton river, the most considerable of all the streams which fall into that bay; the tide ascends this river to Dighton, eight miles above its mouth. Farther east is Buzzards Bay, a deep indentation stretching in a north-eastern direction into the mainland. From its entrance between Seaconet Point and the south-western of the Elizabeth Islands, to its innermost corner, it is 35 miles long, but it lessens in width from ten miles to one mile. The innermost corner is divided from Cape Cod Bay by an isthmus five miles in width. This bay is very much indented by small bays on both shores, but it is shallow, especially towards its inner part; yet vessels of considerable draught may ascend to New Bedford, 16 or 17 miles from its entrance. The shores are low and sandy. On the east of Buzzards Bay begins Barnstable Peninsula, which first stretches from the mainland, a little north of east, 35 miles, varying in width from 3 to 20 miles: it then changes its direction to north and north-west, for about 30 miles, with a mean width of 2½ miles, and terminates in Cape Cod. The difference in the rise of the tide, south and north of the peninsula, is remarkable. In Buzzards Bay and Nantucket Bay it rises from 3½ to 4 feet, and in Cape Cod Bay to 16 feet. Barnstable Peninsula encloses the southern portion of a large bay, which is generally called Massachusetts Bay, though at present that name is limited to the northern portion of it, and the southern, which is enclosed by the peninsula, is called Barnstable Bay or Cape Cod Bay. This large bay extends northwards to Cape Anne in the form of a parallelogram, 55 miles long from south-south-east to north-north-west, and 25 miles in width. From Cape Cod to Cape Anne it is open 44 miles to the Atlantic. It contains the important harbours of Plymouth, Boston, and Salem. North of Cape Anne the shores are somewhat high and rocky.

South of Barnstable Peninsula are the islands of Nantucket and Martha's Vineyard. Nantucket is about [illegible] miles in length and 4 in breadth, rises to a very moderate height, and is level. Its sandy soil is almost entirely [illegible] and the inhabitants live by fishing. It constitutes a separate county, inhabited by 7286 souls in 1820. Martha's Vineyard is about 16 miles in length and 8 in its greatest breadth; the surface is level and the soil sandy, but productive in some places. Together with some smaller islands lying near it, Martha's Vineyard constitutes Dukes County, which in 1820 contained 3295 inhabitants. The [illegible] which is enclosed by these islands on the south, and Barnstable Peninsula on the north, is called Nantucket Bay.

Surface and Soil.—The surface of the Barnstable Peninsula is level, or rather consists of two inclined plains which attain some elevation where they meet. Between Hya[illegible] harbour and Barnstable, the highest level is about [illegible] above low-water in Nantucket Bay; but on the [illegible] which unites the peninsula to the continent, it is [illegible] feet. The soil of this tract is sandy and light, and of an inferior quality, but cultivated with great industry. [illegible] country along the western side of Buzzards Bay and shores of Massachusetts Bay is similar in soil. But the country rises rapidly inland, so that the tide, which amounts to 16 or 18 feet, is only perceptible from 5 to [illegible] from the sea in the rivers. At the back of this low [illegible] is a hilly region, which in the north-eastern districts extends nearly to the shores of the sea, and westward to the valley of the Connecticut river. Its surface is [illegible] diversified by hills and depressions; the soil of the [illegible] deep and strong, and cultivated with considerable [illegible] In this part some hills rise to a considerable elevation, the highest, Mount Wachuset, attaining nearly [illegible] feet. [illegible] of smaller elevation extend towards the Connecticut, but they approach the banks of the river only near [illegible] ton and Hadley. North and south of these places the Connecticut runs through a valley, from two to three miles wide, which is covered by an alluvium of great fertility. West of it the country immediately rises into high hills, which gradually attain the elevation of mountains. Berkshire, the most western district of the state, being traversed from north to south by two continuous ridges, whose more elevated parts are from 2000 to 4000 feet high. The valleys of this district have a very fertile soil.

Rivers.—The western and mountainous region is traversed by the Housatonick, which rises near the north-western corner of the state, and traverses it by a southern course of nearly 50 miles, when it enters Connecticut; it is a very rapid river and not navigable in Massachusetts. The Connecticut enters Massachusetts from New Hampshire, and traverses it by a course of about 70 miles, including its numerous bends. It is navigable for boats in the whole of its course in Massachusetts. [CONNECTICUT.] No considerable river falls into Massachusetts Bay. Charles river, which falls into Boston harbour, though its whole course does not exceed 30 miles, is navigable for about eight miles for large boats, the tide flowing up to Dedham. The Merrimac rises in New Hampshire on the western declivities of the White Mountains, north of 44° N. lat., and runs nearly due south, 50 miles, when it receives a branch from Winnipiseogee lake, and then runs for 52 miles south-south-east, till it is met by the Nashua river from the south-south-west. Below the junction with the Nashua, the Merrimac curves gradually to the east for 12 miles, and afterwards runs to the north-east about 30 miles, when it falls into the Atlantic after a course of more than 150 miles. In its natural state the Merrimac opposed great impediments to navigation. The tide ascends to Haverhill, 18 miles from its mouth, but above it the course of the river is obstructed by several falls and rapids. The lowest is below Chelmsford, where the river falls over a ledge of rock, to avoid which a canal with three locks has been made. Between this ledge of rock and Haverhill the stream, though still rapid, is navigable. Numerous falls and rapids occur within New Hampshire, all which are now avoided by canals. The number of these canals is eleven, and an uninterrupted navigation has thus been effected as far up the river as Concord in New Hampshire. The importance of this river for internal navigation has been much increased by the Middlesex Canal.

Climate.—The climate of Massachusetts is much colder in winter, and warmer in summer, than the southern districts of Great Britain, though the difference of latitude amounts to about nine degrees. The mean temperature seems to be 48°, or about two degrees less than that of London. The winter commences about the middle of December and terminates about the middle of March. In this season the thermometer commonly ranges between 32° and 10°, and sometimes descends below zero of Fahr.; snow covers the ground and the rivers are frozen hard enough to bear loaded waggons. The spring terminates in the middle of May. The summer is hot, and at the solstice the thermometer frequently rises to 77° every day for a month and more; sometimes it attains 90° and even 100°. In the same season it sometimes descends in the night to 50°, whilst at noon it is 76°. The summer lasts to the beginning of October, when the weather grows rapidly colder. The prevalent winds are from the north-west and south. The north-west wind prevails during the whole year, except the summer, when the wind blows mostly from the south or south-west. In winter the coldest wind is from the north-west. Rains are more abundant in winter than in summer. The annual quantity amounts to more than 40 inches, which is nearly double the quantity that falls in many places on the continent of Europe. Yet it is stated that the number of rainy days is fewer in Massachusetts than in most countries of Europe. Slight shocks of earthquakes are not uncommon.

Productions.—As Massachusetts was early settled, a greater portion of its surface is cultivated than in most of the other states, and agriculture has been more improved. The farms generally average from 100 to 200 acres. The principal agricultural productions are, Indian corn, rye, oats, potatoes, hemp, flax, peas, hops, beans, and pumpkins, which last are used as food for swine and cattle. Wheat, buckwheat, and barley are raised only in small quantities. Forests still cover a considerable portion of the surface. In the plains there are only pines, the white pine on a soil consisting of light loam, and the yellow pine on sand and gravel. The hilly and mountainous country produces oak, walnut, birch, maple, ash, cedar, cherry, and chesnut. In the valleys and on the banks of the rivers there are elm, cherry, maple, and aspen. Some marshy places are covered mostly with white cedar. All the fruit-trees of England are cultivated.

The cattle and the hogs are of a good size, especially the former, in the mountainous and hilly country west of Connecticut river. Wolves are still found in the hilly region. Fish abound in the rivers and in the sea. The whale fishery in the sea between Massachusetts and the Great Bank of Newfoundland is still important, though the larger kinds of whales have disappeared, and only the black fish (Delphinus globiceps, Cuv.) comes there in shoals and is taken in considerable numbers by the inhabitants of Nantucket, and the vessels sent from New Bedford in Buzzards Bay. The fishery of cod in Massachusetts Bay and on the banks near Nantucket is still more important, and also that of mackerel. The other fish abounding in the same tract of sea are haddock, herring, halibut, and sturgeon. Lobsters, crabs, and some other shell-fish abound in Massachusetts Bay.

Iron occurs in several places, but is not much worked. There are some traces of copper and lead. Limestone abounds in Berkshire, where some good marble also occurs. Slate is found in one or two places.

Inhabitants.—The population, which during the last century increased very rapidly, at present increases more slowly. The emigration towards the west is considerable. In 1820 the population amounted to 523,287, and in 1830 to 610,408 individuals. According to the last census there were 81 individuals to each square mile. In 1837 it had increased to 691,222 individuals, or more than 91 to each square mile. Massachusetts has no slaves.

Canals and Railroads.—The Middlesex canal begins at Charlestown opposite Boston, and terminates at Chelmsford on the Merrimac; the length is 27 miles; the width at the surface thirty, and at the bottom twenty feet; the depth is three feet. The highest level is 104 feet above Boston harbour. By this canal the countries on both sides of the Merrimac are united with the town of Boston. The Blackstone canal extends from Worcester (which is about half way between Boston and the Connecticut river) to Providence in Rhode Island; the length is 44 miles, of which sixteen are in Rhode Island. The Hampshire and Hampden canal branches off from the Connecticut river at Northampton, and unites with the Farmington canal at the southern boundary-line of Massachusetts; the Farmington canal, which may be considered as its continuation, traverses the state of Connecticut in its whole breadth, terminating at New Haven. The whole line is about 80 miles long, of which about thirty are in Massachusetts.

The Quincy railroad, the first road of this description made in the United States, was constructed for the purpose of transporting the granite of that town to the tide-water; it is 3 miles long. A railroad intended to unite the town of Boston with Albany on the Hudson river in New York, has been completed to Worcester, about 40 miles. Another railroad is constructing from Boston to Lowell, 30 miles; and another from Boston to Providence in Rhode Island, about 40 miles; probably both are completed.

Manufactures.—The manufactures of this state are more considerable than those of any other state of the Union, if its extent and population are considered. The most important branch is the construction of vessels; but the manufactures of cotton and woollen goods, of paper, leather, iron, and glass are also very extensive. Boston has some rope manufactories, sugar-houses, and train-oil distilleries, of which last there are also some in New Bedford and on the island of Nantucket. Straw bonnets are made by the country people in some districts. There are 250 incorporated manufacturing companies in the state.

Commerce; Navigation; Fishery.—The commercial relations of this state, both with foreign countries and the other states of the Union, are extensive and important. The most important articles of export are dried and salt fish, train and spermaceti oil, salted beef, flour, soap, candles, leather, and cotton goods. The imports consist mostly of colonial goods, brought from the West Indies, as coffee, sugar, molasses, indigo, iron, and hemp, together with the manufactured goods of England, especially silk, linen, and woollen. The countries of Europe which the vessels of this state principally visit are England, Russia, and Sweden; from the two latter countries they import great quantities of iron; they also visit China, Brazil, and the English, Spanish, and Danish islands in the West Indies. Massachusetts has more foreign trade than any state of the Union, except New York, and the tonnage of its shipping exceeds even that of New York. By an agreement entered into with England in 1818, the inhabitants of the United States are permitted to fish cod on the western coasts of Newfoundland, the Straits of Belleisle, and the coasts of Labrador; and in this branch of fishery, together with that of the mackerel, more than 1000 vessels and boats belonging to Massachusetts are engaged. New Bedford and the island of Nantucket also send about 250 vessels to the whale and sperm fishery, the tonnage of which amounts to more than 80,000 tons; and when the several vessels are added, which are supplied by Boston, Salem, and Plymouth, the shipping employed by this state, in this branch of industry, probably exceeds 100,000 tons.

The total of the imports from 1st of October, 1832, to 30th of September, 1833, amounted to 19,940,911 dollars, and that of the exports to 9,683,122 dollars, of which latter 5,150,584 dollars were of domestic produce, and 4,532,538 dollars of foreign produce, which clearly shows that many of the states lying farther west receive their imports by way of Massachusetts, but export their produce by another road. In carrying on this trade, more than 225,000 tons of American and somewhat more than 30,000 tons of foreign shipping were employed.

Political Division and Towns.—The state is divided into 28 counties; the capital is Boston. [BOSTON.] Round the Bay of Boston, whose entrance is formed by Point Alderton on the south, and Point Shirley on the North, are some important places, as Quincy, which has quarries of granite, and 4000 inhabitants; Cambridge, the seat of Harvard College, with 6071 inhabitants; and Charlestown, with 8783 inhabitants, and a dockyard belonging to the general government. Cambridge and Charlestown are united to Boston by bridges, and may almost be considered as suburbs. Farther north along the shore is Lynn, with 7000 inhabitants, and extensive manufactures of shoes; Salem, built on a peninsula in Marblehead Harbour, has an extensive commerce, especially with the East Indies, and 13,836 inhabitants; Gloucester, on the south-side of Cape Anne, has a spacious harbour, with 7518 inhabitants, and is engaged in the fisheries; and Newbury Port, a well-built place at the mouth of the Merrimac, with 6388 inhabitants, who are engaged in fishing and commerce. On the shores of Barnstable Bay is Plymouth, with a good harbour; it was the first settlement in the colony, and contains 4751 inhabitants. Barnstable has 4000 inhabitants, and is engaged in the fisheries. On Buzzards Bay is New Bedford, with 7592 inhabitants, who are extensively engaged in the whale fishery and in the manufacture of spermaceti candles and salt. In the interior is Lowell on the Merrimac, with extensive manufactures of cotton and wool; in 1833 more than 36,000,000 yards of cotton goods were made here. Worcester, near the centre of the state, where the railroad and the Blackstone canal meet, has 4172 inhabitants, and some internal commerce. Northampton, on the Connecticut river, has 3613 inhabitants and large tan-yards. Pittsfield, on the banks of the Houssatonic, near the boundary of New York, has 3570 inhabitants, with manufactures of iron and considerable trade.

History.—This part of the American continent was probably discovered by John Cabot at the end of the fifteenth century, but though visited several times during the following century, no settlement was made. A company was chartered by James I. in 1606, to which this country was granted under the name of North Virginia. The first settlement however was only formed in 1620 at Plymouth, by about 120 families of non-conformists, who had fled to Holland, and thence proceeded to Cape Cod. They framed a constitution, and took an oath to keep it. It afterwards became the groundwork of the constitution of the state. The first regular house of representatives was organised in [illegible] The progress of the colony was very slow in the beginning, especially on account of the oppression to which the inhabitants were subjected during the reign of the Stuarts, [illegible] the time of the Commonwealth and after the Restoration. Though they were relieved by the Revolution of [illegible] the increase of the colony was thus promoted, its population in 1730 did not exceed 120,000 individuals. Since that time however it has improved rapidly. In the Revolutionary war Massachusetts took a leading part, by resisting the demands of the English government, and creating a military force. Hostilities were commenced by the battle of Lexington. It adopted a new constitution in 1780, and after Maine, which up to 1819 formed a part of the state, had been separated from it, the constitution was amended for the last time in 1820. According to this constitution the legislature consists of a senate and a house of representatives. The senate is chosen by the counties, each citizen possessed of landed property to the amount of 60 dollars having a vote, but the number of the senators to be chosen by each county depends on its quota of taxes. The other house is chosen by the towns, according to their population, each citizen possessed of 60 dollars having a vote. In 1830 there were 4[illegible] senators and 501 representatives. The executive power is vested in a governor, lieutenant-governor, and nine counsellors. The first two officers are chosen annually by the citizens, and the counsellors by the joint ballot of the two houses from among the persons returned as senators. Massachusetts sends two members to the senate and thirteen to the house of representatives at Washington.

Education.—As generally in the United States, the education of the lower classes is an object attended to by the state. For that purpose the State is divided into small townships, or separate corporations, of from five to seven miles square, and the number of these townships amounts to [illegible] But that the distance which children have to go to attend school may not be too great, each township is divided into smaller districts. In each a school is established, which in summer is attended by the younger children, and conducted by a woman; but in winter it is visited by children from ten to fifteen years old. The children are instructed in orthography, reading, writing, English grammar, geography, and arithmetic. The number of these schools amounts to about 3000; and in winter they are attended by more than 140,000, and in summer by upwards of 120,000 children. These common schools, as they are called, are wholly supported by a tax upon the people. The number of academies and private schools amounts to 854, but a great proportion of them are small establishments, kept in the interval between the winter and summer terms of the district schools. 6 [illegible] larger institutions of this description are attended by the children of wealthier parents, who wish to give them a greater amount of useful knowledge. Their number amounts to more than 60. Among the learned institutions is Harvard College at Cambridge, three miles from Boston, the best endowed institution in the United States; it has an anatomical museum, a botanical garden, a collection of minerals, and a library of 35,000 volumes. There are at present thirty instructors and about two hundred and thirty students. Other collegiate institutions are Williams College at Williamstown, with seven instructors and about [illegible] hundred and twenty students; Amherst College, with twelve instructors and two hundred and sixty students; the Theological Seminary at Andover, which has a deservedly high reputation, and the Newton Theological Seminary.
